Controls enabling of pointer authentication (using the APDBKey_EL1 key) of instruction addresses in the EL3 translation regime.

`0b0` Pointer authentication (using the APDBKey_EL1 key) of data addresses is not enabled.

`0b1` Pointer authentication (using the APDBKey_EL1 key) of data addresses is enabled.

For more information, see *System register control of pointer authentication* on page D5-2510.

Note

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. Specifically, when the field is 1, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When the field is 0, both of these functions are NOP.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL3:

`0b0` All instruction access to Normal memory from EL3 are Non-cacheable for all levels of instruction and unified cache.

If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

`0b1` This control has no effect on the Cacheability of instruction access to Normal memory from EL3.

If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0, EL2, or EL2&0 translation regimes.

In a system where the PE resets into EL3, this field resets to `0`.

EOS, bit [11]

When ARMv8.5-CSEH is implemented:

Exception Exit is Context Synchronizing.

`0b0` An exception return from EL3 is not a context synchronizing event

`0b1` An exception return from EL3 is a context synchronizing event

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If SCTLR_EL3.EOS is set to 0b0:

- Memory transactions, including instruction fetches, from an Exception level always use the translation resources associated with that translation regime.
- Exception Catch debug events are synchronous debug events.
- DCPS* and DRPS instructions are context synchronization events.

The following are not affected by the value of SCTLR_EL3.EOS:

- The indirect write of the PSTATE and PC values from SPSR_EL3 and ELR_EL3 on exception return is synchronized.
- If the PE enters Debug state before the first instruction after an Exception return from EL3 to Non-secure state, any pending Halting debug event completes execution.
- The GIC behavior that allocates interrupts to FIQ or IRQ changes simultaneously with leaving the EL3 Exception level.
- Behavior of accessing the banked copies of the stack pointer using the SP register name for loads, stores and data processing instructions.
- Exit from Debug state.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

Bits [10:7]

Reserved, RES0.

nAA, bit [6]

When ARMv8.4-LSE is implemented:

Non-aligned access. This bit controls generation of Alignment faults at EL3 under certain conditions.

0b0 LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLR, STLRH, STLUR, and STLURH generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes for accesses.

0b1 This control bit does not cause LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAPURW, LDAR, LDARH, LDLAR, LDLARH, STLLR, STLLRH, STLR, STLRH, STLUR, or STLURH to generate an Alignment fault if all bytes being accessed are not within a single 16-byte quantity, aligned to 16 bytes.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL3 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see *SP alignment checking* on page D1-2287.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Cacheability control, for data accesses.

0b0 All data access to Normal memory from EL3, and all Normal memory accesses to the EL3 translation tables, are Non-cacheable for all levels of data and unified cache.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 This control has no effect on the Cacheability of:

- Data access to Normal memory from EL3.
- Normal memory accesses to the EL3 translation tables.

This bit has no effect on the EL1&0, EL2, or EL2&0 translation regimes.

In a system where the PE resets into EL3, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL3.

0b0 Alignment fault checking disabled when executing at EL3.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

0b1 Alignment fault checking enabled when executing at EL3.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

In a system where the PE resets into EL3, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MMU enable for EL3 stage 1 address translation. Possible values of this bit are:

0b0 EL3 stage 1 address translation disabled.

See the SCTLR_EL3.I field for the behavior of instruction accesses to Normal memory.

0b1 EL3 stage 1 address translation enabled.

In a system where the PE resets into EL3, this field resets to 0.

Accessing the SCTLR_EL3

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.108 SCXTNUM_EL0, EL0 Read/Write Software Context Number

The SCXTNUM_EL0 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL0 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configurations

This register is present only when ARMv8.0-CSV2 is implemented. Otherwise, direct accesses to SCXTNUM_EL0 are UNDEFINED.

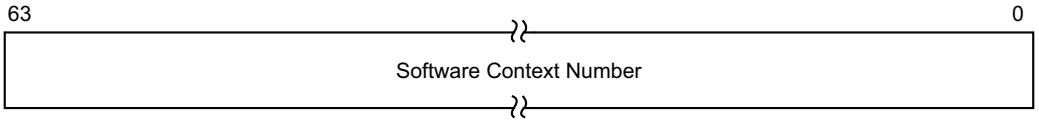
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCXTNUM_EL0 is a 64-bit register.

Field descriptions

The SCXTNUM_EL0 bit assignments are:



Bits [63:0]

Software Context Number. A number to identify the context within the EL0 exception level.

This field resets to an architecturally UNKNOWN value.

D13.2.110 SCXTNUM_EL2, EL2 Read/Write Software Context Number

The SCXTNUM_EL2 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL2 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configurations

This register is present only when ARMv8.0-CSV2 is implemented. Otherwise, direct accesses to SCXTNUM_EL2 are UNDEFINED.

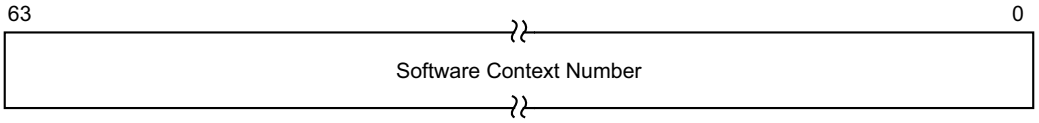
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCXTNUM_EL2 is a 64-bit register.

Field descriptions

The SCXTNUM_EL2 bit assignments are:



Bits [63:0]

Software Context Number. A number to identify the context within the EL2 exception level.

This field resets to an architecturally UNKNOWN value.

Accessing the SCXTNUM_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic SCXTNUM_EL2 or SCXTNUM_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, SCXTNUM_EL2

D13.2.111 SCXTNUM_EL3, EL3 Read/Write Software Context Number

The SCXTNUM_EL3 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL3 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configurations

This register is present only when ARMv8.0-CSV2 is implemented. Otherwise, direct accesses to SCXTNUM_EL3 are UNDEFINED.

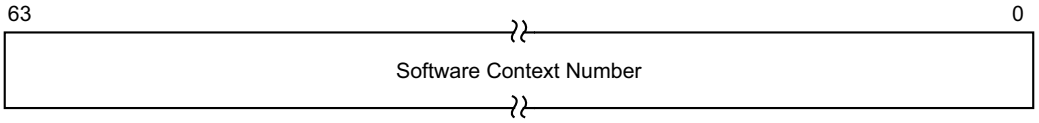
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCXTNUM_EL3 is a 64-bit register.

Field descriptions

The SCXTNUM_EL3 bit assignments are:



Bits [63:0]

Software Context Number. A number to identify the context within the EL3 exception level.

This field resets to an architecturally UNKNOWN value.

Accessing the SCXTNUM_EL3

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, SCXTNUM_EL3

op0	op1	CRn	CRm	op2
0b11	0b110	0b1101	0b0000	0b111

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    UNDEFINED;
elsif PSTATE.EL == EL3 then
    return SCXTNUM_EL3;
```

D13.2.112 TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

Purpose

The control register for stage 1 of the EL1&0 translation regime.

Configurations

AArch64 System register TCR_EL1[31:0] is architecturally mapped to AArch32 System register TTBCR[31:0].

AArch64 System register TCR_EL1[63:32] is architecturally mapped to AArch32 System register TTBCR2[31:0].

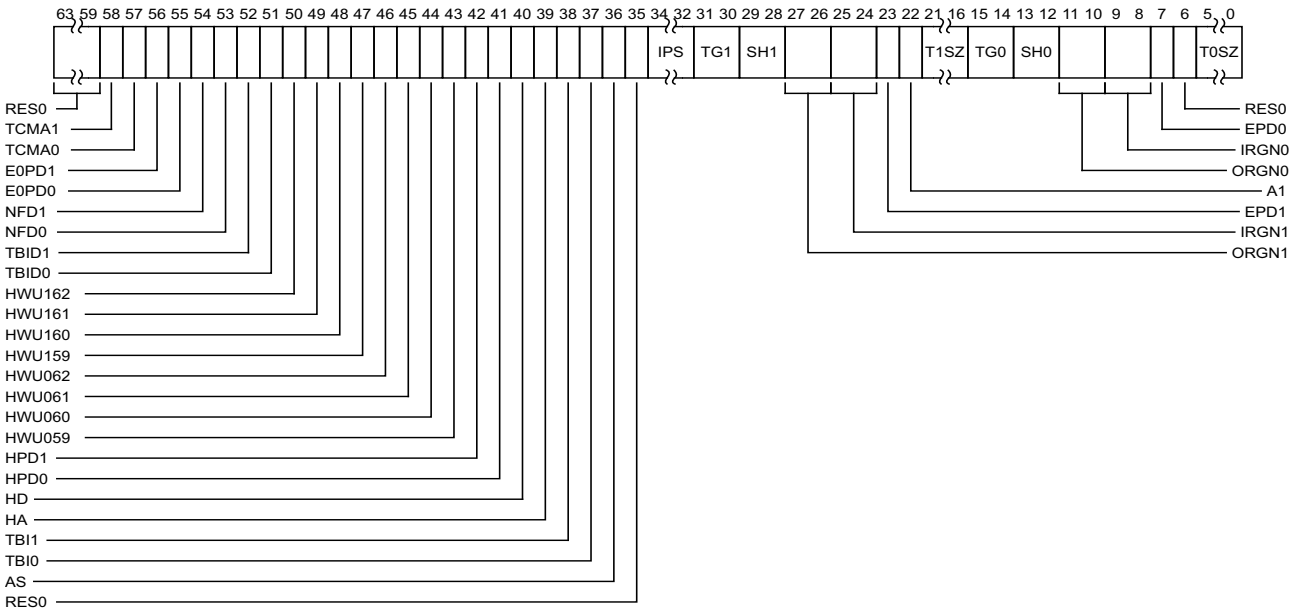
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TCR_EL1 is a 64-bit register.

Field descriptions

The TCR_EL1 bit assignments are:



Any of the bits in TCR_EL1, other than the A1 bit and the EPDx bits when they have the value 1, are permitted to be cached in a TLB.

Bits [63:59]

Reserved, RES0.

TCMA1, bit [58]

When ARMv8.5-MemTag is implemented:

Controls the generation of Unchecked accesses at EL1, and at EL0 if HCR_EL2.{E2H,TGE}!={1,1}, when address[59:55] = 0b11111.

`0b0` This control has no effect on the generation of Unchecked accesses at EL1 or EL0.

`0b1` All accesses at EL1 and EL0 are Unchecked.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Software may change this control bit on a context switch.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TCMA0, bit [57]

When ARMv8.5-MemTag is implemented:

Controls the generation of Unchecked accesses at EL1, and at EL0 if HCR_EL2.{E2H,TGE}!={1,1}, when address[59:55] = 0b00000.

0b0 This control has no effect on the generation of Unchecked accesses at EL1 or EL0.

0b1 All accesses at EL1 and EL0 are Unchecked.

Note

Software may change this control bit on a context switch.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E0PD1, bit [56]

When ARMv8.5-E0PD is implemented:

Faulting control for EL0 access to any address translated by TTBR1_EL1.

0b0 EL0 access to any address translated by TTBR1_EL1 will not generate a fault by this mechanism.

0b1 EL0 access to any address translated by TTBR1_EL1 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E0PD0, bit [55]

When ARMv8.5-E0PD is implemented:

Faulting control for EL0 access to any address translated by TTBR0_EL1.

0b0 EL0 access to any address translated by TTBR0_EL1 will not generate a fault by this mechanism.

0b1 EL0 access to any address translated by TTBR0_EL1 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NFD1, bit [54]

When SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR1_EL1.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR1_EL1.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See *The Scalable Vector Extension (SVE)* on page A2-92 for more information.

Defined values are:

`0b0` Does not disable stage 1 translation table walks using TTBR1_EL1.

`0b1` A TLB miss on a virtual address that is translated using TTBR1_EL1 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NFD0, bit [53]

When SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR0_EL1.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR0_EL1.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See *The Scalable Vector Extension (SVE)* on page A2-92 for more information.

Defined values are:

`0b0` Does not disable stage 1 translation table walks using TTBR0_EL1.

`0b1` A TLB miss on a virtual address that is translated using TTBR0_EL1 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID1, bit [52]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

`0b0` TCR_EL1.TBI1 applies to Instruction and Data accesses.

`0b1` TCR_EL1.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR1_EL1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TBID0, bit [51]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

`0b0` TCR_EL1.TBI0 applies to Instruction and Data accesses.

`0b1` TCR_EL1.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU162, bit [50]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

`0b0` For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU161, bit [49]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

`0b0` For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU160, bit [48]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

`0b0` For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU159, bit [47]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

`0b0` For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU062, bit [46]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

`0b0` For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU061, bit [45]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

`0b0` For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HWU060, bit [44]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

`0b0` For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU059, bit [43]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

`0b0` For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD1, bit [42]

When ARMv8.1-HPD is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR1_EL1.

`0b0` Hierarchical permissions are enabled.

`0b1` Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD0, bit [41]

When ARMv8.1-HPD is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL1.

`0b0` Hierarchical permissions are enabled.

`0b1` Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HD, bit [40]

When ARMv8.1-TTHM is implemented:

Hardware management of dirty state in stage 1 translations from EL0 and EL1.

`0b0` Stage 1 hardware management of dirty state disabled.

`0b1` Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HA, bit [39]

When ARMv8.1-TTHM is implemented:

Hardware Access flag update in stage 1 translations from EL0 and EL1.

`0b0` Stage 1 Access flag update disabled.

`0b1` Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBI1, bit [38]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR1_EL1 region, or ignored and used for tagged addresses. Defined values are:

`0b0` Top Byte used in the address calculation.

`0b1` Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL1.TBID1 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI1 is 1 and bit [55] of the target address to be stored to the PC is 1, then bits[63:56] of that target address are also set to 1 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

TBI0, bit [37]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL1 region, or ignored and used for tagged addresses. Defined values are:

`0b0` Top Byte used in the address calculation.

`0b1` Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL1.TBID0 is 1, then this field only applies to Data accesses.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise, if the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

AS, bit [36]

ASID Size. Defined values are:

`0b0` 8 bit - the upper 8 bits of TTBR0_EL1 and TTBR1_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.

`0b1` 16 bit - the upper 16 bits of TTBR0_EL1 and TTBR1_EL1 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

Bit [35]

Reserved, RES0.

IPS, bits [34:32]

Intermediate Physical Address Size.

`0b000` 32 bits, 4GB.

`0b001` 36 bits, 64GB.

`0b010` 40 bits, 1TB.

`0b011` 42 bits, 4TB.

`0b100` 44 bits, 16TB.

`0b101` 48 bits, 256TB.

`0b110` 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the `0b101` or `0b110` encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value `0b110` is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not `0b110` or a value treated as `0b110`, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL1 are `0b0000`.

This field resets to an architecturally UNKNOWN value.

TG1, bits [31:30]

Granule size for the TTBR1_EL1.

`0b01` 16KB.

`0b10` 4KB.

`0b11` 64KB.

Other values are reserved.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using TTBR1_EL1.

`0b00` Non-shareable.

`0b10` Outer Shareable.

`0b11` Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

This field resets to an architecturally UNKNOWN value.

ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

`0b00` Normal memory, Outer Non-cacheable.

`0b01` Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.

`0b10` Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

`0b11` Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

`0b00` Normal memory, Inner Non-cacheable.

`0b01` Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.

`0b10` Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.

`0b11` Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

EPD1, bit [23]

Translation table walk disable for translations using TTBR1_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL1. The encoding of this bit is:

`0b0` Perform translation table walks using TTBR1_EL1.

`0b1` A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

A1, bit [22]

Selects whether TTBR0_EL1 or TTBR1_EL1 defines the ASID. The encoding of this bit is:

`0b0` TTBR0_EL1.ASID defines the ASID.

`0b1` TTBR1_EL1.ASID defines the ASID.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1SZ, bits [21:16]

The size offset of the memory region addressed by TTBR1_EL1. The region size is $2^{(64-T1SZ)}$ bytes.

The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

TG0, bits [15:14]

Granule size for the TTBR0_EL1.

`0b00` 4KB

`0b01` 64KB

`0b10` 16KB

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL1.

`0b00` Non-shareable

`0b10` Outer Shareable

`0b11` Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

`0b00` Normal memory, Outer Non-cacheable.

`0b01` Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.

`0b10` Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

`0b11` Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

`0b00` Normal memory, Inner Non-cacheable.

`0b01` Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.

`0b10` Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.

`0b11` Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EPD0, bit [7]

Translation table walk disable for translations using TTBR0_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0_EL1. The encoding of this bit is:

`0b0` Perform translation table walks using TTBR0_EL1.

`0b1` A TLB miss on an address that is translated using TTBR0_EL1 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL1. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Accessing the TCR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic TCR_EL1 or TCR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, TCR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.TRVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.<NV2,NV1,NV> == '111' then
        return NVMem[0x120];
    else
        return TCR_EL1;
elsif PSTATE.EL == EL2 then
    if HCR_EL2.E2H == '1' then
        return TCR_EL2;
    else
        return TCR_EL1;
elsif PSTATE.EL == EL3 then
    return TCR_EL1;
```

D13.2.113 TCR_EL2, Translation Control Register (EL2)

The TCR_EL2 characteristics are:

Purpose

The control register for stage 1 of the EL2, or EL2&0, translation regime:

- When the Effective value of HCR_EL2.E2H is 0, this register controls stage 1 of the EL2 translation regime, that supports a single VA range, translated using TTBR0_EL2.
- When the value of HCR_EL2.E2H is 1, this register controls stage 1 of the EL2&0 translation regime, that supports both:
  - A lower VA range, translated using TTBR0_EL2.
  - A higher VA range, translated using TTBR1_EL2.

Configurations

AArch64 System register TCR_EL2[31:0] is architecturally mapped to AArch32 System register HTCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

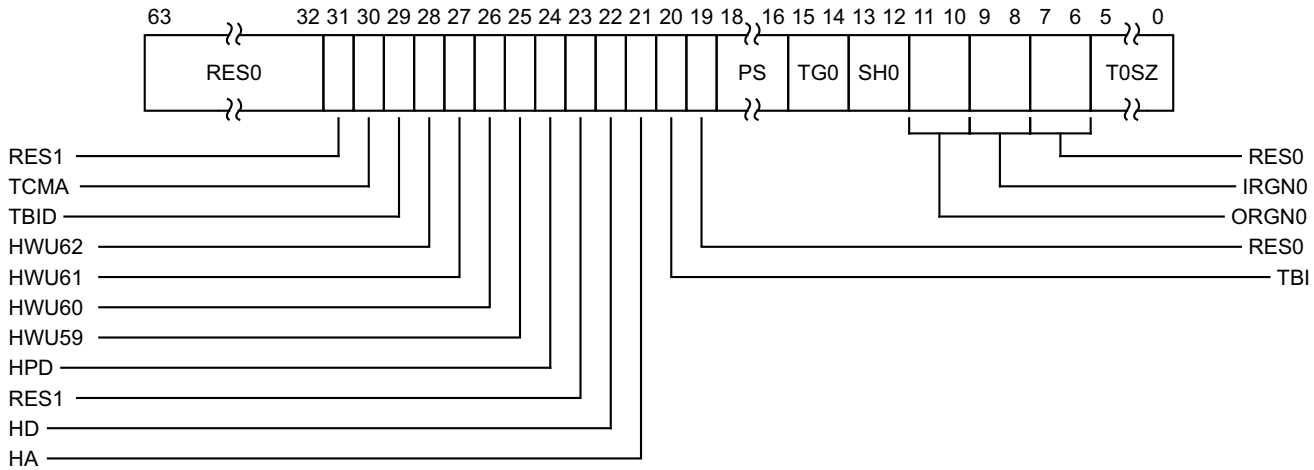
Attributes

TCR_EL2 is a 64-bit register.

Field descriptions

The TCR_EL2 bit assignments are:

When HCR_EL2.E2H == 0:



Any of the bits in TCR_EL2, other than the A1 bit and the EPDx bits when they have the value 1, are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TCMA, bit [30]

When ARMv8.5-MemTag is implemented:

Controls the generation of Unchecked accesses at EL2 when address [59:56] = `0b0000`.

`0b0` This control has no effect on the generation of Unchecked accesses.

`0b1` All accesses are Unchecked.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID, bit [29]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

`0b0` TCR_EL2.TBI applies to Instruction and Data accesses.

`0b1` TCR_EL2.TBI applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU62, bit [28]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

`0b0` Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU61, bit [27]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

`0b0` Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HWU60, bit [26]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

`0b0` Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU59, bit [25]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

`0b0` Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD, bit [24]

When ARMv8.1-HPD is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL2.

`0b0` Hierarchical permissions are enabled.

`0b1` Hierarchical permissions are disabled.

Note

In this case bit[61] (APTable[0]) and bit[59] (PXNTable) of the next level descriptor attributes are required to be ignored by the PE, and are no longer reserved, allowing them to be used by software.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [23]

Reserved, RES1.

HD, bit [22]

When ARMv8.1-TTHM is implemented:

Hardware management of dirty state in stage 1 translations from EL2.

`0b0` Stage 1 hardware management of dirty state disabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HA, bit [21]

When ARMv8.1-TTHM is implemented:

Hardware Access flag update in stage 1 translations from EL2.

`0b0` Stage 1 Access flag update disabled.

`0b1` Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBI, bit [20]

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

`0b0` Top Byte used in the address calculation.

`0b1` Top Byte ignored in the address calculation.

This affects addresses generated in EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2, or EL2&0, translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL2.TBID is 1, then this field only applies to Data accesses.

If the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL2.
- An exception taken to EL2.
- An exception return to EL2.

This field resets to an architecturally UNKNOWN value.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

`0b000` 32 bits, 4GB.

`0b001` 36 bits, 64GB.

`0b010` 40 bits, 1TB.

`0b011` 42 bits, 4TB.

`0b100` 44 bits, 16TB.

`0b101` 48 bits, 256TB.

`0b110` 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the `0b101` or `0b110` encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value 0b110 is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL2 are 0b0000.

This field resets to an architecturally UNKNOWN value.

TG0, bits [15:14]

Granule size for the TTBR0_EL2.

0b00 4KB.

0b01 64KB.

0b10 16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00 Non-shareable.

0b10 Outer Shareable.

0b11 Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00 Normal memory, Outer Non-cacheable.

0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00 Normal memory, Inner Non-cacheable.

0b01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

Bits [7:6]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

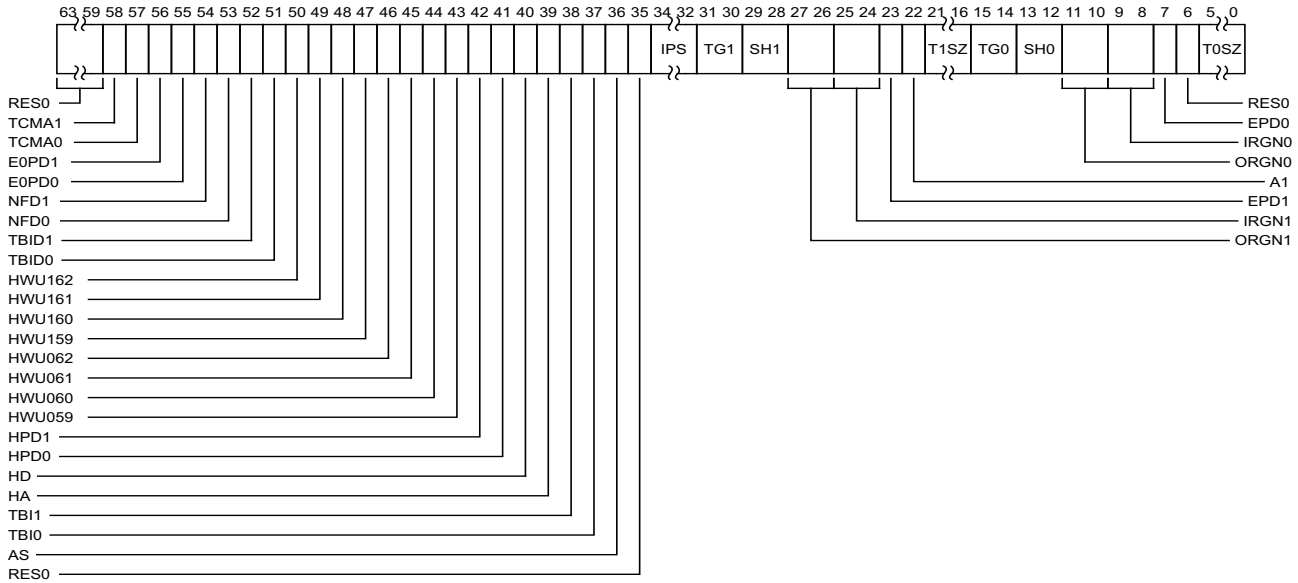
T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL2. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

When ARMv8.1-VHE is implemented and HCR_EL2.E2H == 1:



This view of the register is only valid from Armv8.1 when HCR_EL2.E2H is 1.

Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

Bits [63:59]

Reserved, RES0.

TCMA1, bit [58]

When ARMv8.5-MemTag is implemented:

Controls the generation of Unchecked accesses at EL2, and at EL0 if HCR_EL2.TGE=1, when address[59:55] = `0b11111`.

`0b0` This control has no effect on the generation of Unchecked accesses at EL2 or EL0.

`0b1` All accesses are Unchecked.

Note

Software may change this control bit on a context switch.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TCMA0, bit [57]

When ARMv8.5-MemTag is implemented:

Controls the generation of Unchecked accesses at EL2, and at EL0 if HCR_EL2.TGE=1, when address[59:55] = `0b00000`.

`0b0` This control has no effect on the generation of Unchecked accesses at EL2 or EL0.

`0b1` All accesses are Unchecked.

Note

Software may change this control bit on a context switch.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E0PD1, bit [56]

When ARMv8.5-E0PD is implemented:

Faulting control for EL0 access to any address translated by TTBR1_EL2.

`0b0` EL0 access to any address translated by TTBR1_EL2 will not generate a fault by this mechanism.

`0b1` EL0 access to any address translated by TTBR1_EL2 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E0PD0, bit [55]

When ARMv8.5-E0PD is implemented:

Faulting control for EL0 access to any address translated by TTBR0_EL2.

`0b0` EL0 access to any address translated by TTBR0_EL2 will not generate a fault by this mechanism.

`0b1` EL0 access to any address translated by TTBR0_EL2 will generate a level 0 translation fault

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NFD1, bit [54]

When SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR1_EL2.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR1_EL2.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See *The Scalable Vector Extension (SVE)* on page A2-92 for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Defined values are:

0b0 Does not disable stage 1 translation table walks using TTBR1_EL2.

0b1 A TLB miss on a virtual address that is translated using TTBR1_EL2 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NFD0, bit [53]

When SVE is implemented:

Non-fault translation table walk disable for stage 1 translations using TTBR0_EL2.

This bit controls whether to perform a stage 1 translation table walk in response to a non-fault access from EL0 for a virtual address that is translated using TTBR0_EL2.

If SVE is implemented, the affected access types include:

- All accesses due to an SVE non-fault contiguous load instruction.
- Accesses due to an SVE first-fault gather load instruction that are not for the First active element. Accesses due to an SVE first-fault contiguous load instruction are not affected.
- Accesses due to prefetch instructions might be affected, but the effect is not architecturally visible.

See *The Scalable Vector Extension (SVE)* on page A2-92 for more information.

Defined values are:

0b0 Does not disable stage 1 translation table walks using TTBR0_EL2.

0b1 A TLB miss on a virtual address that is translated using TTBR0_EL2 due to the specified access types causes the access to fail without taking an exception. No stage 1 translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID1, bit [52]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

0b0 TCR_EL2.TBI1 applies to Instruction and Data accesses.

0b1 TCR_EL2.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR1_EL2.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID0, bit [51]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

0b0 TCR_EL2.TBI0 applies to Instruction and Data accesses.

0b1 TCR_EL2.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL2.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU162, bit [50]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

`0b0` For translations using TTBR1_EL2, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL2, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU161, bit [49]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

`0b0` For translations using TTBR1_EL2, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL2, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU160, bit [48]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

`0b0` For translations using TTBR1_EL2, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL2, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HWU159, bit [47]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL2.

`0b0` For translations using TTBR1_EL2, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR1_EL2, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD1 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU062, bit [46]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

`0b0` For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU061, bit [45]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

`0b0` For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU060, bit [44]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

`0b0` For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU059, bit [43]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

0b0 For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL2.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL2.HPD0 is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD1, bit [42]

When ARMv8.1-HPD is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR1_EL2.

0b0 Hierarchical permissions are enabled.

0b1 Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD0, bit [41]

When ARMv8.1-HPD is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL2.

0b0 Hierarchical permissions are enabled.

0b1 Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HD, bit [40]

When ARMv8.1-TTHM is implemented:

Hardware management of dirty state in stage 1 translations from EL2.

0b0 Stage 1 hardware management of dirty state disabled.

0b1 Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HA, bit [39]

When ARMv8.1-TTHM is implemented:

Hardware Access flag update in stage 1 translations from EL2.

0b0 Stage 1 Access flag update disabled.

0b1 Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBI1, bit [38]

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR1_EL2 region, or ignored and used for tagged addresses.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

0b0 Top Byte used in the address calculation.

0b1 Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL2 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL2. It has an effect whether the EL2, or EL2&0, translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL2.TBID1 is 1, then this field only applies to Data accesses.

If the value of TBI1 is 1 and bit [55] of the target address to be stored to the PC is 1, then bits[63:56] of that target address are also set to 1 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

TBI0, bit [37]

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

0b0 Top Byte used in the address calculation.

0b1 Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2, or EL2&0, translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL2.TBID0 is 1, then this field only applies to Data accesses.

If the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AS, bit [36]

ASID Size. Defined values are:

`0b0` 8 bit - the upper 8 bits of TTBR0_EL2 and TTBR1_EL2 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.

`0b1` 16 bit - the upper 16 bits of TTBR0_EL2 and TTBR1_EL2 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

Bit [35]

Reserved, RES0.

IPS, bits [34:32]

Intermediate Physical Address Size.

`0b000` 32 bits, 4GB.

`0b001` 36 bits, 64GB.

`0b010` 40 bits, 1TB.

`0b011` 42 bits, 4TB.

`0b100` 44 bits, 16TB.

`0b101` 48 bits, 256TB.

`0b110` **When ARMv8.2-LPA is implemented** 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the `0b101` or `0b110` encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value `0b110` is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not `0b110` or a value treated as `0b110`, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL2 are `0b0000`.

This field resets to an architecturally UNKNOWN value.

TG1, bits [31:30]

Granule size for the TTBR1_EL2.

`0b01` 16KB.

`0b10` 4KB.

`0b11` 64KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using TTBR1_EL2. Defined values are:

0b00 Non-shareable.

0b10 Outer Shareable.

0b11 Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

This field resets to an architecturally UNKNOWN value.

ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL2.

0b00 Normal memory, Outer Non-cacheable.

0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL2.

0b00 Normal memory, Inner Non-cacheable.

0b01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

EPD1, bit [23]

Translation table walk disable for translations using TTBR1_EL2. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL2. The encoding of this bit is:

0b0 Perform translation table walks using TTBR1_EL2.

0b1 A TLB miss on an address that is translated using TTBR1_EL2 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

A1, bit [22]

Selects whether TTBR0_EL2 or TTBR1_EL2 defines the ASID. The encoding of this bit is:

0b0 TTBR0_EL2.ASID defines the ASID.

0b1 TTBR1_EL2.ASID defines the ASID.

This field resets to an architecturally UNKNOWN value.

T1SZ, bits [21:16]

The size offset of the memory region addressed by TTBR1_EL2. The region size is $2^{(64-T1SZ)}$ bytes.

The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TG0, bits [15:14]

Granule size for the TTBR0_EL2.

0b00 4KB.

0b01 64KB.

0b10 16KB.

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00 Non-shareable.

0b10 Outer Shareable.

0b11 Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00 Normal memory, Outer Non-cacheable.

0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

0b00 Normal memory, Inner Non-cacheable.

0b01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

EPD0, bit [7]

Translation table walk disable for translations using TTBR0_EL2. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0_EL2. The encoding of this bit is:

0b0 Perform translation table walks using TTBR0_EL2.

0b1 A TLB miss on an address that is translated using TTBR0_EL2 generates a Translation fault. No translation table walk is performed.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL2. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Accessing the TCR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TCR_EL2 or TCR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, TCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;

D13.2.114 TCR_EL3, Translation Control Register (EL3)

The TCR_EL3 characteristics are:

Purpose

The control register for stage 1 of the EL3 translation regime.

Configurations

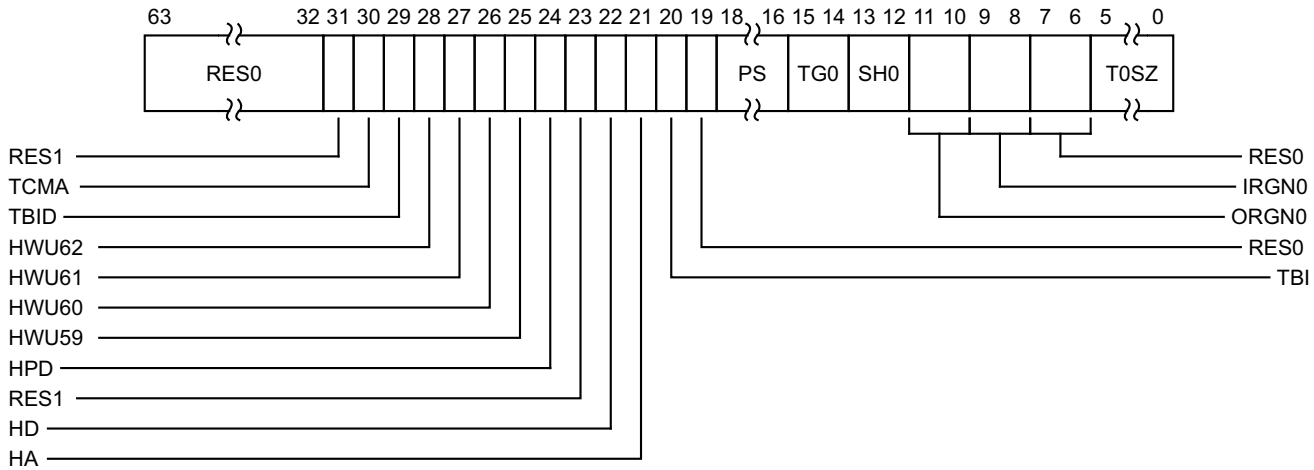
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TCR_EL3 is a 64-bit register.

Field descriptions

The TCR_EL3 bit assignments are:



Any of the bits in TCR_EL3 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

TCMA, bit [30]

When ARMv8.5-MemTag is implemented:

Controls the generation of Unchecked accesses at EL3 when address [59:56] = `0b0000`.

`0b0` This control has no effect on the generation of Unchecked accesses.

`0b1` All accesses are Unchecked.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID, bit [29]

When ARMv8.3-PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

`0b0` TCR_EL3.TBI applies to Instruction and Data accesses.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 TCR_EL3.TBI applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL3.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU62, bit [28]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry.

0b0 Bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU61, bit [27]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry.

0b0 Bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU60, bit [26]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry.

0b0 Bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

0b1 Bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HWU59, bit [25]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry.

`0b0` Bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL3.HPD is 1.

The Effective value of this field is 0 if the value of TCR_EL3.HPD is 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD, bit [24]

When ARMv8.1-HPD is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL3.

`0b0` Hierarchical permissions are enabled.

`0b1` Hierarchical permissions are disabled.

Note

In this case bit[61] (APTable[0]) and bit[59] (PXNTable) of the next level descriptor attributes are required to be ignored by the PE, and are no longer reserved, allowing them to be used by software.

When disabled, the permissions are treated as if the bits are zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [23]

Reserved, RES1.

HD, bit [22]

When ARMv8.1-TTHM is implemented:

Hardware management of dirty state in stage 1 translations from EL3.

`0b0` Stage 1 hardware management of dirty state disabled.

`0b1` Stage 1 hardware management of dirty state enabled, only if the HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HA, bit [21]

When ARMv8.1-TTHM is implemented:

Hardware Access flag update in stage 1 translations from EL3.

`0b0` Stage 1 Access flag update disabled.

`0b1` Stage 1 Access flag update enabled.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TBI, bit [20]

Top Byte Ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL3 region, or ignored and used for tagged addresses.

`0b0` Top Byte used in the address calculation.

`0b1` Top Byte ignored in the address calculation.

This affects addresses generated in EL3 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL3. It has an effect whether the EL3 translation regime is enabled or not.

If ARMv8.3-PAuth is implemented and TCR_EL3.TBID is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL3.
- A exception taken to EL3.
- An exception return to EL3.

For more information, see *Address tagging in AArch64 state* on page D5-2506.

Note

This control determines the scope of address tagging. It never causes an exception to be generated.

This field resets to an architecturally UNKNOWN value.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

`0b000` 32 bits, 4GB.

`0b001` 36 bits, 64GB.

`0b010` 40 bits, 1TB.

`0b011` 42 bits, 4TB.

`0b100` 44 bits, 16TB.

`0b101` 48 bits, 256TB.

`0b110` 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the `0b101` or `0b110` encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value `0b110` is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not `0b110` or a value treated as `0b110`, then bits[51:48] of every translation table base address for the stage of translation controlled by TCR_EL3 are `0b0000`.

This field resets to an architecturally UNKNOWN value.

TG0, bits [15:14]

Granule size for the TTBR0_EL3.

`0b00` 4KB.

`0b01` 64KB.

`0b10` 16KB.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL3.

`0b00` Non-shareable.

`0b10` Outer Shareable.

`0b11` Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

`0b00` Normal memory, Outer Non-cacheable.

`0b01` Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.

`0b10` Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

`0b11` Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

`0b00` Normal memory, Inner Non-cacheable.

`0b01` Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.

`0b10` Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.

`0b11` Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

Bits [7:6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL3. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

This field resets to an architecturally UNKNOWN value.

Accessing the TCR_EL3

Accesses to this register use the following encodings in the System instruction encoding space:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

D13.2.115 TFSRE0_EL1, Tag Fail Status Register (EL0).

The TFSRE0_EL1 characteristics are:

Purpose

Holds accumulated Tag Check Fails occurring in EL0 which are not taken precisely.

Configurations

This register is present only when ARMv8.5-MemTag is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to TFSRE0_EL1 are UNDEFINED.

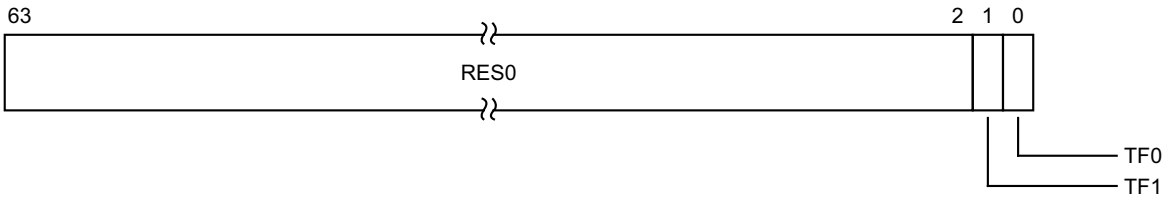
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TFSRE0_EL1 is a 64-bit register.

Field descriptions

The TFSRE0_EL1 bit assignments are:



Bits [63:2]

Reserved, RES0.

TF1, bit [1]

Tag Check Fail. Asynchronously set to 1 when a Tag Check fail using a virtual address with bit<55>==0b1 occurs.

This field resets to an architecturally UNKNOWN value.

TF0, bit [0]

Tag Check Fail. Asynchronously set to 1 when a Tag Check fail using a virtual address with bit<55>==0b0 occurs.

This field resets to an architecturally UNKNOWN value.

Accessing the TFSRE0_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.116 TFSR_EL1, Tag Fail Status Register (EL1).

The TFSR_EL1 characteristics are:

Purpose

Holds accumulated Tag Check Fails occurring in EL1 which are not taken precisely.

Configurations

This register is present only when ARMv8.5-MemTag is implemented and ID_AA64PFR1_EL1_EL1.MTE != 0b0001. Otherwise, direct accesses to TFSR_EL1 are UNDEFINED.

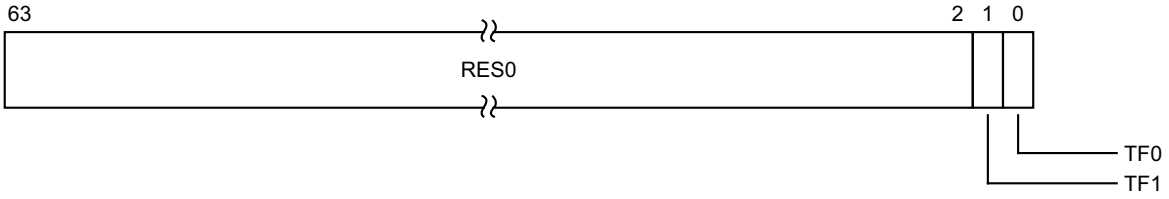
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TFSR_EL1 is a 64-bit register.

Field descriptions

The TFSR_EL1 bit assignments are:



Bits [63:2]

Reserved, RES0.

TF1, bit [1]

Tag Check Fail. Asynchronously set to 1 when a Tag Check fail using a virtual address with bit<55>==0b1 occurs.

This field resets to an architecturally UNKNOWN value.

TF0, bit [0]

Tag Check Fail. Asynchronously set to 1 when a Tag Check fail using a virtual address with bit<55>==0b0 occurs.

This field resets to an architecturally UNKNOWN value.

Accessing the TFSR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.117 TFSR_EL2, Tag Fail Status Register (EL2).

The TFSR_EL2 characteristics are:

Purpose

Holds accumulated Tag Check Fails occurring in EL2 which are not taken precisely.

Configurations

This register is present only when ARMv8.5-MemTag is implemented and ID_AA64PFR1_EL1.MTE != 0b0001. Otherwise, direct accesses to TFSR_EL2 are UNDEFINED.

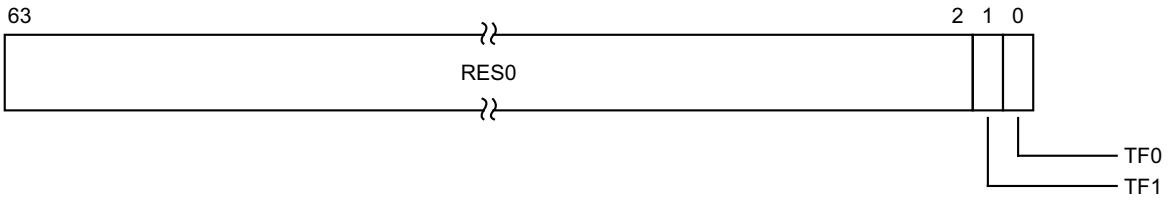
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TFSR_EL2 is a 64-bit register.

Field descriptions

The TFSR_EL2 bit assignments are:



Bits [63:2]

Reserved, RES0.

TF1, bit [1]

Tag Check Fail. Asynchronously set to 1 when a Tag Check fail using a virtual address with bit<55>==0b1 occurs.

When HCR_EL2.E2H==0b0, this field is RES0.

This field resets to an architecturally UNKNOWN value.

TF0, bit [0]

Tag Check Fail. Asynchronously set to 1 when a Tag Check fail using a virtual address with bit<55>==0b0 occurs.

This field resets to an architecturally UNKNOWN value.

Accessing the TFSR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TFSR_EL2 or TFSR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.119 TPIDR_EL0, EL0 Read/Write Software Thread ID Register

The TPIDR_EL0 characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch64 System register TPIDR_EL0[31:0] is architecturally mapped to AArch32 System register TPIDRURW[31:0].

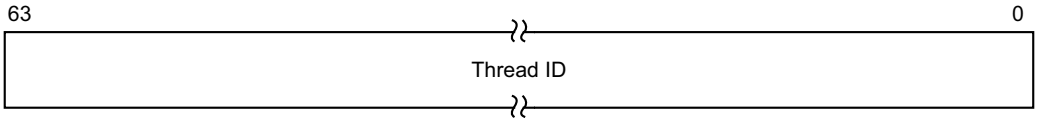
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL0 is a 64-bit register.

Field descriptions

The TPIDR_EL0 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

This field resets to an architecturally UNKNOWN value.

Accessing the TPIDR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.120 TPIDR_EL1, EL1 Software Thread ID Register

The TPIDR_EL1 characteristics are:

Purpose

Provides a location where software executing at EL1 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch64 System register TPIDR_EL1[31:0] is architecturally mapped to AArch32 System register TPIDRPRW[31:0].

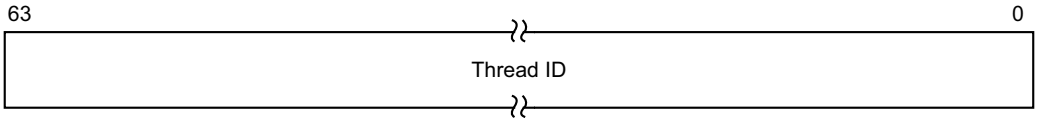
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL1 is a 64-bit register.

Field descriptions

The TPIDR_EL1 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

This field resets to an architecturally UNKNOWN value.

Accessing the TPIDR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, TPIDR_EL1

D13.2.121 TPIDR_EL2, EL2 Software Thread ID Register

The TPIDR_EL2 characteristics are:

Purpose

Provides a location where software executing at EL2 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch64 System register TPIDR_EL2[31:0] is architecturally mapped to AArch32 System register HTPIDR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

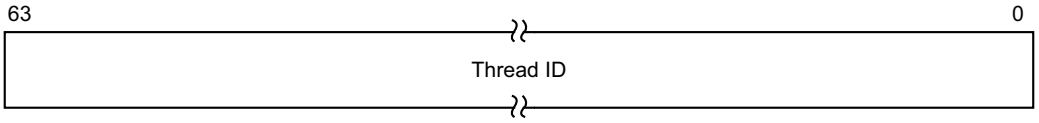
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL2 is a 64-bit register.

Field descriptions

The TPIDR_EL2 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

This field resets to an architecturally UNKNOWN value.

Accessing the TPIDR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.122 TPIDR_EL3, EL3 Software Thread ID Register

The TPIDR_EL3 characteristics are:

Purpose

Provides a location where software executing at EL3 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configurations

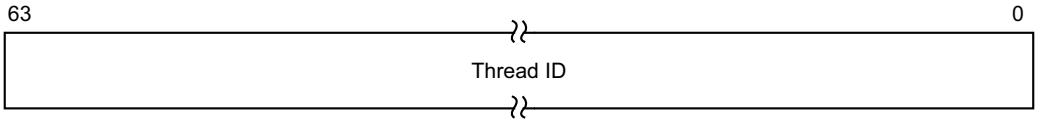
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL3 is a 64-bit register.

Field descriptions

The TPIDR_EL3 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

This field resets to an architecturally UNKNOWN value.

Accessing the TPIDR_EL3

D13.2.123 TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register

The TPIDRRO_EL0 characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch64 System register TPIDRRO_EL0[31:0] is architecturally mapped to AArch32 System register TPIDRURO[31:0].

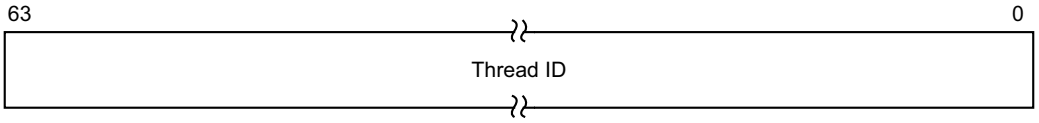
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDRRO_EL0 is a 64-bit register.

Field descriptions

The TPIDRRO_EL0 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRRO_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.124 TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL1&0 translation regime, and other information for this translation regime.

Configurations

AArch64 System register TTBR0_EL1[63:0] is architecturally mapped to AArch32 System register TTBR0[63:0].

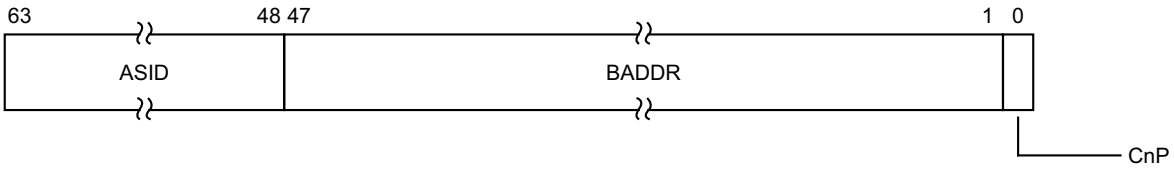
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR0_EL1 is a 64-bit register.

Field descriptions

The TTBR0_EL1 bit assignments are:



ASID, bits [63:48]

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

This field resets to an architecturally UNKNOWN value.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x], bits[47:1].

Note

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL1.IPS is `0b110`, then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

Note

- In an implementation that includes ARMv8.2-LPA a TCR_EL1.IPS value of `0b110`, that selects an IPA size of 52 bits, is permitted only when using the 64KB translation granule.
- When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL1.IPS is `0b110` and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL1.IPS is not `0b110` then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are `0b0000`.

Note

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any TTBR0_EL1[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1.

`0b0` The translation table entries pointed to by TTBR0_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR0_EL1 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR0_EL1.CnP on those other PEs.
- The value of the current ASID.
- If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` The translation table entries pointed to by TTBR0_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1 and all of the following apply:

- The translation table entries are pointed to by TTBR0_EL1.
- The translation tables relate to the same translation regime.
- The ASID is the same as the current ASID.
- If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

This field is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR0_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7630.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR0_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic TTBR0_EL1 or TTBR0_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.125 TTBR0_EL2, Translation Table Base Register 0 (EL2)

The TTBR0_EL2 characteristics are:

Purpose

When HCR_EL2.E2H is 0, holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL2 translation regime, and other information for this translation regime.

When HCR_EL2.E2H is 1, holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL2&0 translation regime, and other information for this translation regime.

Configurations

AArch64 System register TTBR0_EL2[47:1] is architecturally mapped to AArch32 System register HTTBR[47:1].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

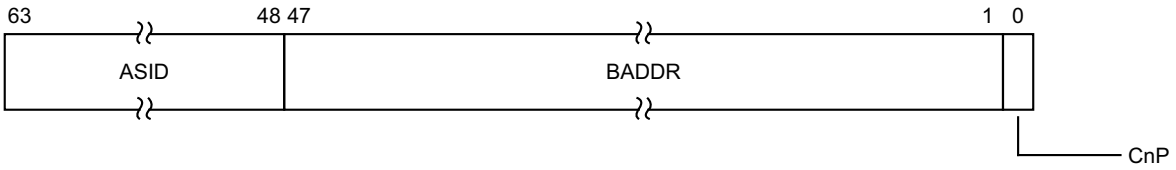
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR0_EL2 is a 64-bit register.

Field descriptions

The TTBR0_EL2 bit assignments are:



ASID, bits [63:48]

When ARMv8.1-VHE is implemented:

When HCR_EL2.E2H is 0, this field is RES0.

When HCR_EL2.E2H is 1, it holds an ASID for the translation table base address. The TCR_EL2.A1 field selects either TTBR0_EL2.ASID or TTBR1_EL2.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x], bits[47:1].

Note

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL2.{I}PS is 0b110, then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

Note

In an implementation that includes ARMv8.2-LPA:

- A TCR_EL2.{I}PS value of 0b110, that selects an OA size of 52 bits, is permitted only when using the 64KB translation granule.
- The OA size is specified by:
  - The value of TCR_EL2.PS when the value of HCR_EL2.E2H is 0.
  - The value of TCR_EL2.IPS when the value of HCR_EL2.E2H is 1.

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL2.{I}PS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL2.{I}PS is not 0b110 then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

Note

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any TTBR0_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL2.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

Non-Confidential

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL2.CnP is 1.

`0b0` The translation table entries pointed to by TTBR0_EL2 for the current translation regime, and ASID if applicable, are permitted to differ from corresponding entries for TTBR0_EL2 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR0_EL2.CnP on those other PEs.
- When the current translation regime is the EL2&0 regime, the value of the current ASID.

`0b1` The translation table entries pointed to by TTBR0_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL2.CnP is 1 and all of the following apply:

- The translation table entries are pointed to by TTBR0_EL2.
- The translation tables relate to the same translation regime.
- If that translation regime is the EL2&0 regime, the ASID is the same as the current ASID.

This field is permitted to be cached in a TLB.

Note

If the value of the TTBR0_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL2s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7630.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR0_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TTBR0_EL2 or TTBR0_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, TTBR0_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;

D13.2.126 TTBR0_EL3, Translation Table Base Register 0 (EL3)

The TTBR0_EL3 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL3 translation regime, and other information for this translation regime.

Configurations

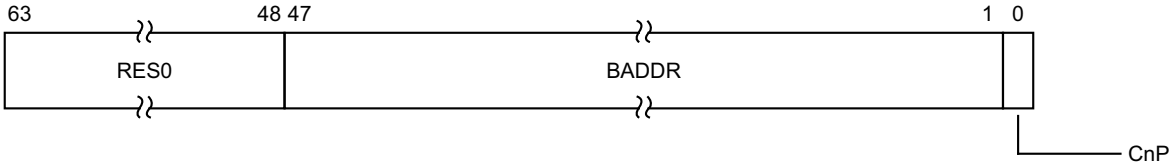
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR0_EL3 is a 64-bit register.

Field descriptions

The TTBR0_EL3 bit assignments are:



Bits [63:48]

Reserved, RES0.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x].

Note

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL3.PS is `0b110` then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- In an implementation that includes ARMv8.2-LPA a TCR_EL3.PS value of `0b110`, that selects a PA size of 52 bits, is permitted only when using the 64KB translation granule.
- When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL3.PS is `0b110` and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL3.PS is not `0b110` then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are `0b0000`.

Note

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any TTBR0_EL3[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR0_EL3, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL3.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL3 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL3.CnP is 1.

`0b0` The translation table entries pointed to by TTBR0_EL3, for the current translation regime, are permitted to differ from corresponding entries for TTBR0_EL3 for other PEs in the Inner Shareable domain. This is not affected by the value of TTBR0_EL3.CnP on those other PEs.

`0b1` The translation table entries pointed to by TTBR0_EL3 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL3.CnP is 1 and the translation table entries are pointed to by TTBR0_EL3.

This field is permitted to be cached in a TLB.

Note

If the value of the TTBR0_EL3.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL3s do not point to the same translation table entries the results of translations using TTBR0_EL3 are CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7630.

This field resets to an architecturally UNKNOWN value.

D13.2.127 TTBR1_EL1, Translation Table Base Register 1 (EL1)

The TTBR1_EL1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL1&0 stage 1 translation regime, and other information for this translation regime.

Configurations

AArch64 System register TTBR1_EL1[63:0] is architecturally mapped to AArch32 System register TTBR1[63:0].

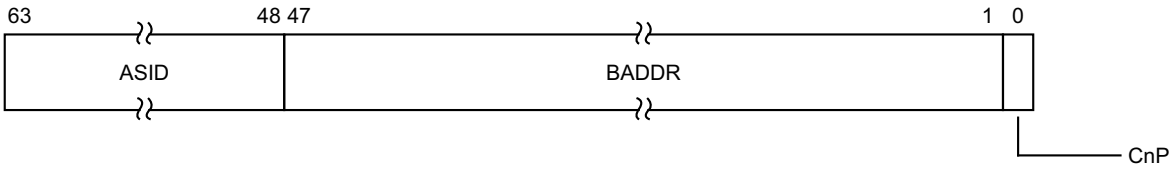
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR1_EL1 is a 64-bit register.

Field descriptions

The TTBR1_EL1 bit assignments are:



ASID, bits [63:48]

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

This field resets to an architecturally UNKNOWN value.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x], bits[47:1].

Note

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL1.IPS is `0b110`, then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

Note

- In an implementation that includes ARMv8.2-LPA a TCR_EL1.IPS value of `0b110`, that selects an IPA size of 52 bits, is permitted only when using the 64KB translation granule.
- When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL1.IPS is `0b110` and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL1.IPS is not `0b110` then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are `0b0000`.

Note

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any TTBR1_EL1[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR1_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T1SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TBR1_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1.

`0b0` The translation table entries pointed to by TTBR1_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR1_EL1 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR1_EL1.CnP on those other PEs.
- The value of the current ASID.
- If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 The translation table entries pointed to by TTBR1_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1 and all of the following apply:

- The translation table entries are pointed to by TTBR1_EL1.
- The translation tables relate to the same translation regime.
- The ASID is the same as the current ASID.
- If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

This field is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR1_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7630.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR1_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic TTBR1_EL1 or TTBR1_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, TTBR1_EL1

op0	op1	CRn	CRm	op2

D13.2.128 TTBR1_EL2, Translation Table Base Register 1 (EL2)

The TTBR1_EL2 characteristics are:

Purpose

When HCR_EL2.E2H is 1, holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL2&0 translation regime, and other information for this translation regime.

Note

When HCR_EL2.E2H is 0, the contents of this register are ignored by the PE, except for a direct read or write of the register.

Configurations

This register is present only when ARMv8.1-VHE is implemented. Otherwise, direct accesses to TTBR1_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

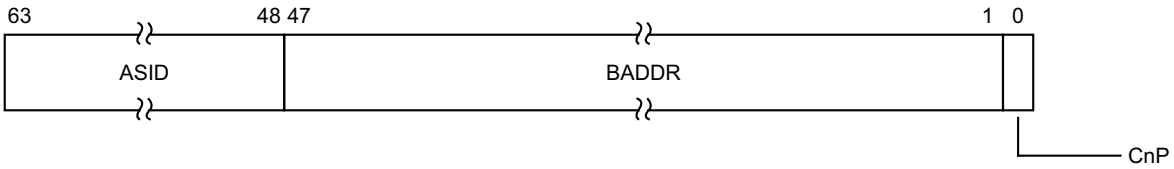
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR1_EL2 is a 64-bit register.

Field descriptions

The TTBR1_EL2 bit assignments are:



ASID, bits [63:48]

An ASID for the translation table base address. The TCR_EL2.A1 field selects either TTBR0_EL2.ASID or TTBR1_EL2.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

This field resets to an architecturally UNKNOWN value.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x], bits[47:1].

Note

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an implementation that includes ARMv8.2-LPA, if the value of TCR_EL2.{I}PS is 0b110, then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP bit[0] of the stage 1 translation table base address is zero.

Note

- In an implementation that includes ARMv8.2-LPA a TCR_EL2.IPS value of 0b110, that selects an OA size of 52 bits, is permitted only when using the 64KB translation granule.
- When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of TCR_EL2.IPS is 0b110 and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of TCR_EL2.IPS is not 0b110 then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs, then bits[51:48] of the translation table base addresses used in this stage of translation are 0b0000.

Note

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any TTBR1_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using TTBR1_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL2.T1SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

Non-Confidential

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TBR1_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1_EL2.CnP is 1.

`0b0` The translation table entries pointed to by TTBR1_EL2 for the current ASID are permitted to differ from corresponding entries for TTBR1_EL2 for other PEs in the Inner Shareable domain. This is not affected by:

- The value of TTBR1_EL2.CnP on those other PEs.
- The value of the current ASID.

`0b1` The translation table entries pointed to by TTBR1_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1_EL2.CnP is 1 and all of the following apply:

- The translation table entries are pointed to by TTBR1_EL2.
- The ASID is the same as the current ASID.

This field is permitted to be cached in a TLB.

Note

- TTBR1_EL2 is accessible only when the value of HCR_EL2.E2H is 1, meaning the current translation regime is the EL2&0 regime.
- If the value of the TTBR1_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1_EL2s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7630.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the TTBR1_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic TTBR1_EL2 or TTBR1_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.129 VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL1.

Configurations

AArch64 System register VBAR_EL1[31:0] is architecturally mapped to AArch32 System register VBAR[31:0].

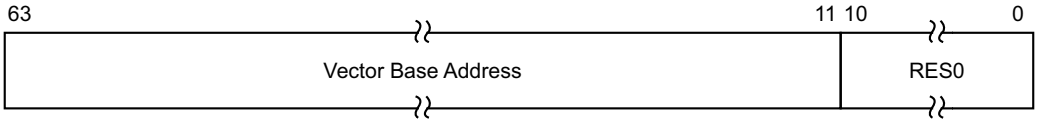
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VBAR_EL1 is a 64-bit register.

Field descriptions

The VBAR_EL1 bit assignments are:



Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL1.

If the implementation does not support ARMv8.2-LVA, then:

- If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If the implementation supports ARMv8.2-LVA, then:

- If tagged addresses are being used, bits [55:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

This field resets to an architecturally UNKNOWN value.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic VBAR_EL1 or VBAR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.2.130 VBAR_EL2, Vector Base Address Register (EL2)

The VBAR_EL2 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL2.

Configurations

AArch64 System register VBAR_EL2[31:0] is architecturally mapped to AArch32 System register HVBAR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

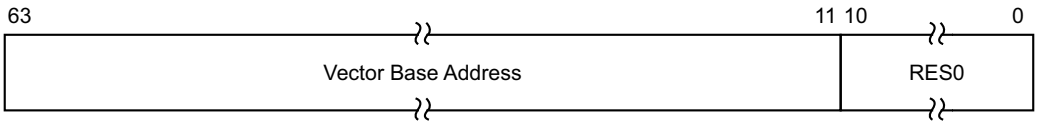
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VBAR_EL2 is a 64-bit register.

Field descriptions

The VBAR_EL2 bit assignments are:



Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL2.

If the implementation does not support ARMv8.2-LVA, then:

- If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.

If the implementation supports ARMv8.2-LVA, then:

- If tagged addresses are being used, bits [55:52] of VBAR_EL2 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL2 must be the same or else the use of the vector address will result in a recursive exception.

This field resets to an architecturally UNKNOWN value.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic VBAR_EL2 or VBAR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

D13.2.132 VMPIDR_EL2, Virtualization Multiprocessor ID Register

The VMPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by EL1 reads of MPIDR_EL1.

Configurations

AArch64 System register VMPIDR_EL2[31:0] is architecturally mapped to AArch32 System register VMPIDR[31:0].

If EL2 is not implemented, reads of this register return the value of the MPIDR_EL1, and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

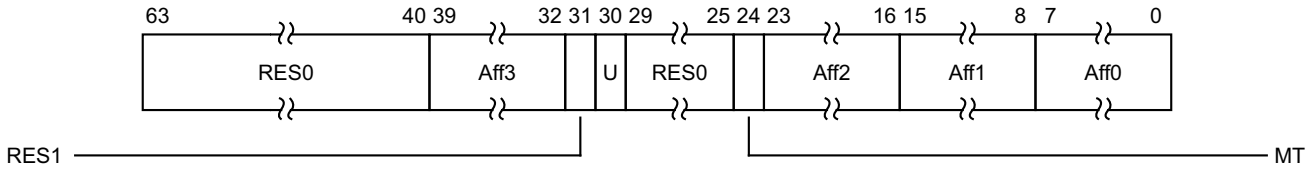
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VMPIDR_EL2 is a 64-bit register.

Field descriptions

The VMPIDR_EL2 bit assignments are:



Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. See the description of Aff0 for more information.

Aff3 is not supported in AArch32 state.

This field resets to an architecturally UNKNOWN value.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

`0b0` Processor is part of a multiprocessor system.

`0b1` Processor is part of a uniprocessor system.

This field resets to an architecturally UNKNOWN value.

Bits [29:25]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of Aff0 for more information about affinity levels. The possible values of this bit are:

`0b0` Performance of PEs at the lowest affinity level is largely independent.

`0b1` Performance of PEs at the lowest affinity level is very interdependent.

This field resets to an architecturally UNKNOWN value.

Aff2, bits [23:16]

Affinity level 2. See the description of Aff0 for more information.

This field resets to an architecturally UNKNOWN value.

Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

This field resets to an architecturally UNKNOWN value.

Aff0, bits [7:0]

Affinity level 0. This is the affinity level that is most significant for determining PE behavior. Higher affinity levels are increasingly less significant in determining PE behavior. The assigned value of the MPIDR.{Aff2, Aff1, Aff0} or MPIDR_EL1.{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

This field resets to an architecturally UNKNOWN value.

Accessing the VMPIDR_EL2

D13.2.133 VNCR_EL2, Virtual Nested Control Register

The VNCR_EL2 characteristics are:

Purpose

When ARMv8.4-NV is implemented, holds the base address that is used to define the memory location that is accessed by transformed reads and writes of System registers.

Configurations

This register is present only when ARMv8.4-NV is implemented. Otherwise, direct accesses to VNCR_EL2 are UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

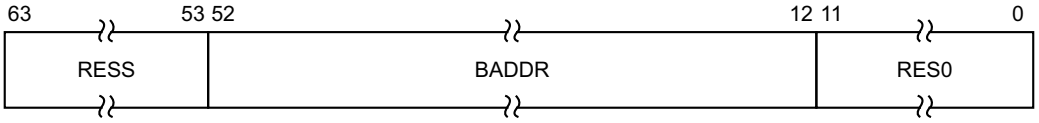
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VNCR_EL2 is a 64-bit register.

Field descriptions

The VNCR_EL2 bit assignments are:



RESS, bits [63:53]

Reserved, Sign extended. If the bits marked as RESS do not all have the same value, then there is a CONSTRAINED UNPREDICTABLE choice between:

- Generating an EL2 translation regime Translation abort on use of the VNCR_EL2 register.
- Bits[63:49] of VNCR_EL2 are treated as the same value as bit[48] for all purposes other than reading back the register.
- Bits[63:49] of VNCR_EL2 are treated as the same value as bit[48] for all purposes.
- If the virtual address space for EL2 supports more than 48 bits, bits[63:53] of VNCR_EL2 are treated as the same value as bit[52] for all purposes other than reading back the register.
- If the virtual address space for EL2 supports more than 48 bits, bits[63:53] of VNCR_EL2 are treated as the same value as bit[52].

Where the EL2 translation regime has upper and lower address ranges, bit[52] is used to select between those address ranges to determine if the address space supports more than 48 bits.

BADDR, bits [52:12]

Base Address. If the virtual address space for EL2 does not support more than 48 bits, then bits [52:49] are RESS.

When a register read/write is transformed to be a Load or Store, the address of the load/store is to SignOffset(VNCR.BADDR:Offset<11:0>, 64).

This field resets to an architecturally UNKNOWN value.

Bits [11:0]

Reserved, RES0.

D13.2.134 VPIDR_EL2, Virtualization Processor ID Register

The VPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by EL1 reads of MIDR_EL1.

Configurations

AArch64 System register VPIDR_EL2[31:0] is architecturally mapped to AArch32 System register VPIDR[31:0].

If EL2 is not implemented, reads of this register return the value of the MIDR_EL1, and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

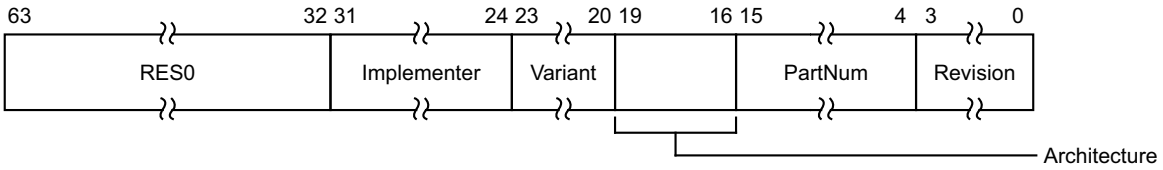
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VPIDR_EL2 is a 64-bit register.

Field descriptions

The VPIDR_EL2 bit assignments are:



Bits [63:32]

Reserved, RES0.

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	Arm Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Hex representation	ASCII representation	Implementer
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

This field resets to an architecturally UNKNOWN value.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field resets to an architecturally UNKNOWN value.

Architecture, bits [19:16]

The permitted values of this field are:

0b0001 Armv4.

0b0010 Armv4T.

0b0011 Armv5 (obsolete).

0b0100 Armv5T.

0b0101 Armv5TE.

0b0110 Armv5TEJ.

0b0111 Armv6.

0b1111 Architectural features are individually identified in the ID_* registers, see *ID registers* on page K14-7832.

All other values are reserved.

This field resets to an architecturally UNKNOWN value.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

This field resets to an architecturally UNKNOWN value.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

This field resets to an architecturally UNKNOWN value.

Accessing the VPIDR_EL2

D13.2.135 VSTCR_EL2, Virtualization Secure Translation Control Register

The VSTCR_EL2 characteristics are:

Purpose

The control register for stage 2 of the Secure EL1&0 translation regime.

Configurations

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to VSTCR_EL2 are UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

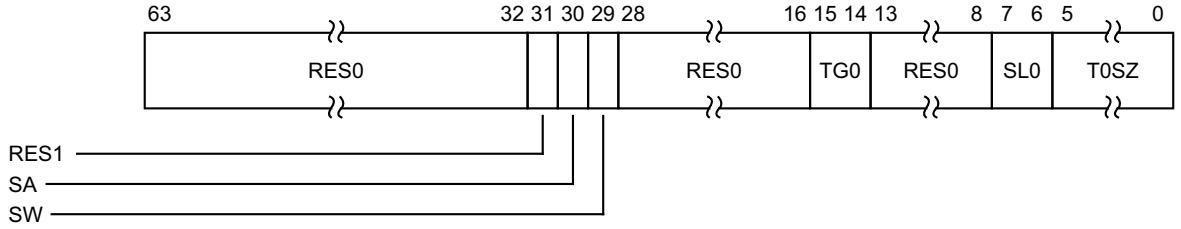
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VSTCR_EL2 is a 64-bit register.

Field descriptions

The VSTCR_EL2 bit assignments are:



Any of the bits in VSTCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

SA, bit [30]

Secure stage 2 translation output address space.

0b0 All stage 2 translations for the Secure IPA space access the Secure PA space.

0b1 All stage 2 translations for the Secure IPA space access the Non-secure PA space.

When the value of VSTCR_EL2.SW is 1, this bit behaves as 1 for all purposes other than reading back the value of the bit.

This field resets to an architecturally UNKNOWN value.

SW, bit [29]

Secure stage 2 translation address space.

0b0 All stage 2 translation table walks for the Secure IPA space are to the Secure PA space.

0b1 All stage 2 translation table walks for the Secure IPA space are to the Non-secure PA space.

This field resets to an architecturally UNKNOWN value.

Bits [28:16]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TG0, bits [15:14]

Secure stage 2 granule size for VSTTBR_EL2.

`0b00` 4KB.

`0b01` 64KB.

`0b10` 16KB.

Other values are reserved.

If ARMv8.5-GTG is implemented, ID_AA64MMFR0_EL1.{TGran4_2, TGran16_2, TGran64_2} indicate which granule sizes are supported for Level 2 translation.

If ARMv8.5-GTG is not implemented, ID_AA64MMFR0_EL1.{TGran4, TGran16, TGran64} indicate which granule sizes are supported.

If the value is programmed to either a reserved value, or a size that has not been implemented, then for all purposes other than read back from this register, the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

Bits [13:8]

Reserved, RES0.

SL0, bits [7:6]

When ARMv8.4-TTST is implemented:

Starting level of the Secure stage 2 translation lookup, controlled by VSTCR_EL2. The meaning of this field depends on the value of VSTCR_EL2.TG0.

`0b00` If VSTCR_EL2.TG0 is `0b00` (4KB granule), start at level 2. If VSTCR_EL2.TG0 is `0b10` (16KB granule) or `0b01` (64KB granule), start at level 3.

`0b01` If VSTCR_EL2.TG0 is `0b00` (4KB granule), start at level 1. If VSTCR_EL2.TG0 is `0b10` (16KB granule) or `0b01` (64KB granule), start at level 2.

`0b10` If VSTCR_EL2.TG0 is `0b00` (4KB granule), start at level 0. If VSTCR_EL2.TG0 is `0b10` (16KB granule) or `0b01` (64KB granule), start at level 1.

`0b11` If VSTCR_EL2.TG0 is `0b00` (4KB granule), start at level 3.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VSTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Starting level of the Secure stage 2 translation lookup, controlled by VSTCR_EL2. The meaning of this field depends on the value of VSTCR_EL2.TG0.

`0b00` If VSTCR_EL2.TG0 is `0b00` (4KB granule), start at level 2. If VSTCR_EL2.TG0 is `0b10` (16KB granule) or `0b01` (64KB granule), start at level 3.

`0b01` If VSTCR_EL2.TG0 is `0b00` (4KB granule), start at level 1. If VSTCR_EL2.TG0 is `0b10` (16KB granule) or `0b01` (64KB granule), start at level 2.

`0b10` If VSTCR_EL2.TG0 is `0b00` (4KB granule), start at level 0. If VSTCR_EL2.TG0 is `0b10` (16KB granule) or `0b01` (64KB granule), start at level 1.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VSTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T0SZ, bits [5:0]

The size offset of the memory region addressed by VSTTBR_EL2. The region size is $2^{(64-VSTCR_EL2.T0SZ)}$ bytes.

The maximum and minimum possible values for this field depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

If this field is programmed to a value that is not consistent with the programming of SL0, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Accessing the VSTCR_EL2

D13.2.136 VSTTBR_EL2, Virtualization Secure Translation Table Base Register

The VSTTBR_EL2 characteristics are:

Purpose

The base register for stage 2 of the Secure EL1&0 translation regime. Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the Secure EL1&0 translation regime, and other information for this translation stage.

Configurations

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to VSTTBR_EL2 are UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

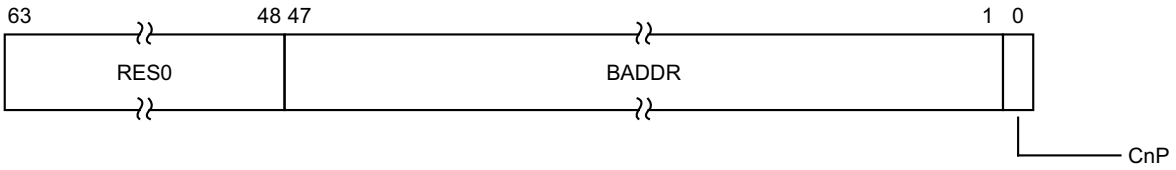
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VSTTBR_EL2 is a 64-bit register.

Field descriptions

The VSTTBR_EL2 bit assignments are:



Any of the bits in VSTTBR_EL2 are permitted to be cached in a TLB.

Bits [63:48]

Reserved, RES0.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x].

Note

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

If the value of VTCR_EL2.PS is `0b110`, then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Bits[5:2] of the stage 1 translation table base address are zero.

Note

When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of VTCR_EL2.PS is `0b110` and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of VTCR_EL2.PS is not `0b110` then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs then bits[51:48] of the translation table base addresses used in this stage of translation are `0b0000`.

If any VSTTBR_EL2[47:1] bit that is defined as RES0 has the value 1 when a translation table walk is performed using VSTTBR_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of VSTCR_EL2.T0SZ, the stage of translation, and the translation granule size.

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

Common not Private, for stage 2 of the Secure EL1&0 translation regime. In an implementation that includes ARMv8.2-TTCNP, indicates whether each entry that is pointed to by VSTTBR_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VSTTBR_EL2.CnP is 1.

`0b0` The translation table entries pointed to by VSTTBR_EL2 are permitted to differ from the entries for VSTTBR_EL2 for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

`0b1` The translation table entries pointed to by VSTTBR_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VSTTBR_EL2.CnP is 1 and the VMID is the same as the current VMID.

Note

If the value of VSTTBR_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VSTTBR_EL2s do not point to the same translation table entries when using the current VMID, then the results of translations using VSTTBR_EL2 are CONSTRAINED UNPREDICTABLE, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6254.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

This field resets to an architecturally UNKNOWN value.

D13.2.137 VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

Purpose

The control register for stage 2 of the EL1&0 translation regime.

Configurations

AArch64 System register VTCR_EL2[31:0] is architecturally mapped to AArch32 System register VTCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

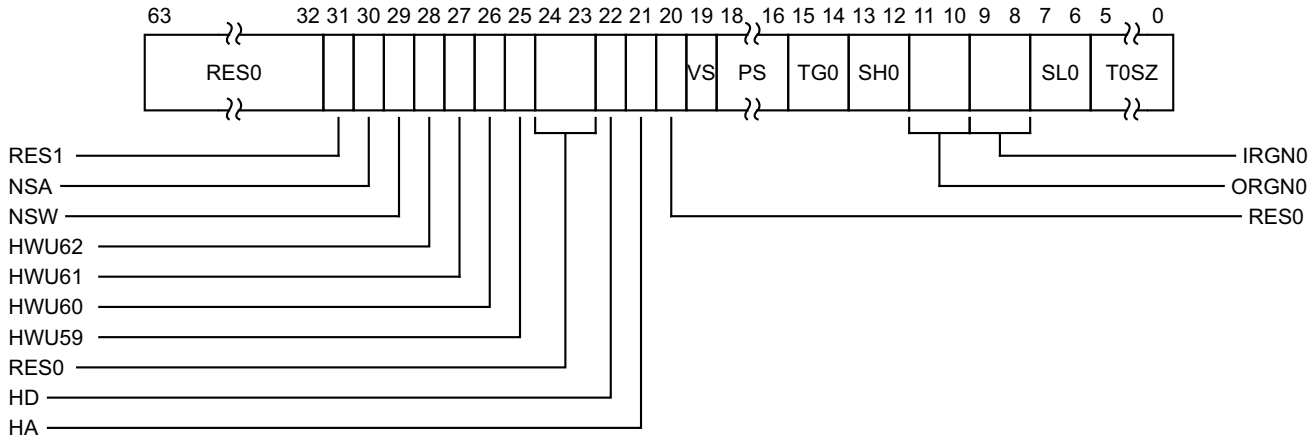
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTCR_EL2 is a 64-bit register.

Field descriptions

The VTCR_EL2 bit assignments are:



Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

NSA, bit [30]

When ARMv8.4-SecEL2 is implemented:

Non-secure stage 2 translation output address space.

`0b0` All stage 2 translations for the Non-secure IPA space of the Secure EL1&0 translation regime access the Secure PA space.

`0b1` All stage 2 translations for the Non-secure IPA space of the Secure EL1&0 translation regime access the Non-secure PA space.

This bit behaves as 1 for all purposes other than reading back the value of the bit when one of the following is true:

- The PE is executing in Non-secure state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The value of VTCR_EL2.NSW is 1.
- The value of VSTCR_EL2.SA is 1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NSW, bit [29]

When ARMv8.4-SecEL2 is implemented:

Non-secure stage 2 translation table address space.

`0b0` All stage 2 translation table walks for the Non-secure IPA space of the Secure EL1&0 translation regime are to the Secure PA space.

`0b1` All stage 2 translation table walks for the Non-secure IPA space of the Secure EL1&0 translation regime are to the Non-secure PA space.

When the PE is executing in Non-secure state, this bit behaves as 1 for all purposes other than reading back the value of the bit.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU62, bit [28]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 2 translation table Block or Page entry.

`0b0` Bit[62] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[62] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU61, bit [27]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 2 translation table Block or Page entry.

`0b0` Bit[61] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[61] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU60, bit [26]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 2 translation table Block or Page entry.

`0b0` Bit[60] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` Bit[60] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU59, bit [25]

When ARMv8.2-TTPBHA is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 2 translation table Block or Page entry.

`0b0` Bit[59] of each stage 2 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

`0b1` Bit[59] of each stage 2 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [24:23]

Reserved, RES0.

HD, bit [22]

When ARMv8.1-TTHM is implemented:

Hardware management of dirty state in stage 2 translations when EL2 is enabled in the current Security state.

`0b0` Stage 2 hardware management of dirty state disabled.

`0b1` Stage 2 hardware management of dirty state enabled, only if the VTCR_EL2.HA bit is also set to 1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HA, bit [21]

When ARMv8.1-TTHM is implemented:

Hardware Access flag update in Non-secure and Secure stage 2 translations when EL2 is enabled in the current Security state.

`0b0` Stage 2 Access flag update disabled.

`0b1` Stage 2 Access flag update enabled.

Otherwise:

Reserved, RES0.

Bit [20]

Reserved, RES0.

VS, bit [19]

When ARMv8.1-VMID16 is implemented:

VMID Size.

`0b0` 8 bit - the upper 8 bits of VTTBR_EL2 and VSTTBR_EL2 are ignored by the hardware, and treated as if they are all zeros, for every purpose except when reading back the register.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 16 bit - the upper 8 bits of VTTBR_EL2 and VSTTBR_EL2 are used for allocation and matching in the TLB.

If the implementation only supports an 8-bit VMID, this field is RES0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PS, bits [18:16]

Physical address Size for the Second Stage of translation.

0b000 32 bits, 4GB.

0b001 36 bits, 64GB.

0b010 40 bits, 1TB.

0b011 42 bits, 4TB.

0b100 44 bits, 16TB.

0b101 48 bits, 256TB.

0b110 52 bits, 4PB.

Other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The value 0b110 is permitted only if ARMv8.2-LPA is implemented and the translation granule size is 64KB.

In an implementation that supports 52-bit PAs, if the value of this field is not 0b110 or a value treated as 0b110, then bits[51:48] of every translation table base address for the stage of translation controlled by VTCR_EL2 are 0b0000.

This field resets to an architecturally UNKNOWN value.

TG0, bits [15:14]

Granule size for the VTTBR_EL2.

0b00 4KB.

0b01 64KB.

0b10 16KB.

Other values are reserved.

If ARMv8.5-GTG is implemented, ID_AA64MMFR0_EL1.{TGran4_2, TGran16_2, TGran64_2} indicate which granule sizes are supported for Level 2 translation.

If ARMv8.5-GTG is not implemented, ID_AA64MMFR0_EL1.{TGran4, TGran16, TGran64} indicate which granule sizes are supported.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

This field resets to an architecturally UNKNOWN value.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

0b00 Non-shareable.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b10 Outer Shareable.

0b11 Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

This field resets to an architecturally UNKNOWN value.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

0b00 Normal memory, Outer Non-cacheable.

0b01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using VTTBR_EL2 or VSTTBR_EL2.

0b00 Normal memory, Inner Non-cacheable.

0b01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.

0b10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.

0b11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

This field resets to an architecturally UNKNOWN value.

SL0, bits [7:6]

When ARMv8.4-TTST is implemented:

Starting level of the Secure stage 2 translation lookup, controlled by VTCR_EL2. The meaning of this field depends on the value of VTCR_EL2.TG0.

0b00 If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 3.

0b01 If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 2.

0b10 If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 1.

0b11 If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 3.

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Starting level of the Secure stage 2 translation lookup, controlled by VTCR_EL2. The meaning of this field depends on the value of VTCR_EL2.TG0.

0b00 If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 2. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 3.

0b01 If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 1. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 2.

0b10 If VTCR_EL2.TG0 is 0b00 (4KB granule), start at level 0. If VTCR_EL2.TG0 is 0b10 (16KB granule) or 0b01 (64KB granule), start at level 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of VTCR_EL2.T0SZ, then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

T0SZ, bits [5:0]

The size offset of the memory region addressed by VTTBR_EL2. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 0 Translation fault is generated.

This field resets to an architecturally UNKNOWN value.

Accessing the VTCR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, VTCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0001	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        return NVMem[0x040];
    elsif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL2 then
    return VTCR_EL2;
elsif PSTATE.EL == EL3 then
    return VTCR_EL2;
```

MSR VTCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0001	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && HCR_EL2.<NV2,NV> == '11' then
        NVMem[0x040] = X[t];
    elsif EL2Enabled() && HCR_EL2.NV == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL2 then
    VTCR_EL2 = X[t];
elsif PSTATE.EL == EL3 then
    VTCR_EL2 = X[t];
```

D13.2.138 VTTBR_EL2, Virtualization Translation Table Base Register

The VTTBR_EL2 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the EL1&0 translation regime, and other information for this translation regime.

Configurations

AArch64 System register VTTBR_EL2[63:0] is architecturally mapped to AArch32 System register VTTBR[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

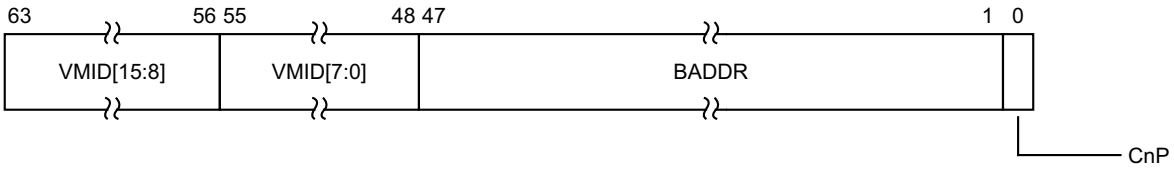
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTTBR_EL2 is a 64-bit register.

Field descriptions

The VTTBR_EL2 bit assignments are:



VMID[15:8], bits [63:56]

When ARMv8.1-VMID16 is implemented:

Extension to VMID[7:0]. See VMID[7:0] for more details.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [55:48]

The VMID for the translation table.

It is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

If the implementation has an 8-bit VMID, then VMID[15:8] are RES0.

If the implementation has a 16-bit VMID, then:

- The VTCR_EL2.VS bit selects whether VMID[15:8] are ignored by the hardware for every purpose except reading back the register, or whether these bits are used for allocation and matching in the TLB.
- The 16-bit VMID is only supported when EL2 is using AArch64. This means the hardware must ignore VMID[15:8] when EL2 is using AArch32.

This field resets to an architecturally UNKNOWN value.

BADDR, bits [47:1]

Translation table base address, A[47:x] or A[51:x], bits[47:1].

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Translation table base addresses of 52 bits, A[51:x], are supported only in an implementation that includes ARMv8.2-LPA and is using the 64KB translation granule.
- A translation table must be aligned to the size of the table, except that when using a translation table base address larger than 48 bits the minimum alignment of a table containing fewer than eight entries is 64 bytes.

In an implementation that includes ARMv8.2-LPA, if the value of VTCR_EL2.PS is `0b110`, then:

- Register bits[47:z] hold bits[47:z] of the stage 1 translation table base address, where z is determined as follows:
  - If x >= 6 then z=x.
  - Otherwise, z=6.
- Register bits[5:2] hold bits[51:48] of the stage 1 translation table base address.
- When z>x register bits[(z-1):x] are RES0, and bits[(z-1):x] of the translation table base address are zero.
- When x>6 register bits[(x-1):6] are RES0.
- Register bit[1] is RES0.
- Bits[5:2] of the stage 1 translation table base address are zero.
- In an implementation that includes ARMv8.2-TTCNP, bit[0] of the stage 1 translation table base address is zero.

Note

- In an implementation that includes ARMv8.2-LPA a VTCR_EL2.PS value of `0b110`, that selects a PA size of 52 bits, is permitted only when using the 64KB translation granule.
- When the value of ID_AA64MMFR0_EL1.PARange indicates that the implementation does not support a 52 bit PA size, if a translation table lookup uses this register with the 64KB translation granule when the value of VTCR_EL2.PS is `0b110` and the value of register bits[5:2] is nonzero, an Address size fault is generated.

If the Effective value of VTCR_EL2.PS is not `0b110` then:

- Register bits[47:x] hold bits[47:x] of the stage 1 translation table base address.
- Register bits[(x-1):1] are RES0.
- If the implementation supports 52-bit PAs and IPAs then bits[51:48] of the translation table base addresses used in this stage of translation are `0b0000`.

Note

This definition applies:

- To an implementation that includes ARMv8.2-LPA and is using a translation granule smaller than 64KB.
- To any implementation that does not include ARMv8.2-LPA.

If any VTTBR_EL2[47:0] bit that is defined as RES0 has the value 1 when a translation table walk is performed using VTTBR_EL2, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits[x-1:0] of the translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of VTCR_EL2.T0SZ, the stage of translation, and the translation granule size.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field resets to an architecturally UNKNOWN value.

CnP, bit [0]

When ARMv8.2-TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by VTTBR_EL2 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VTTBR_EL2.CnP is 1.

`0b0` The translation table entries pointed to by VTTBR_EL2 are permitted to differ from the entries for VTTBR_EL2 for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.

`0b1` The translation table entries pointed to by VTTBR_EL2 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VTTBR_EL2.CnP is 1 and the VMID is the same as the current VMID.

This field is permitted to be cached in a TLB.

Note

If the value of VTTBR_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VTTBR_EL2s do not point to the same translation table entries when using the current VMID then the results of translations using VTTBR_EL2 are CONSTRAINED UNPREDICTABLE, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7630.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the VTTBR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, VTTBR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0001	0b000

```
if PSTATE.EL == EL0 then

D13.3 Debug registers

This section lists the Debug System registers in AArch64 state, in alphabetic order:

- The principal encoding space for debug registers is `op0==0b10`, `op1==` {0, 3, 4}. *Instructions for accessing debug System registers* on page D12-2801 summarizes the registers in this encoding space and lists them in order of their encodings.
- In addition, the following registers in the `op0==0b11` encoding space are classified as Debug registers:
  - DLR_EL0.
  - DSPSR_EL0.
  - MDCR_EL2.
  - MDCR_EL3.
  - SDER32_EL3.

Non-Confidential

D13.3.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Configurations

AArch64 System register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to AArch32 System register DBGAUTHSTATUS[31:0].

AArch64 System register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to External register DBGAUTHSTATUS_EL1[31:0].

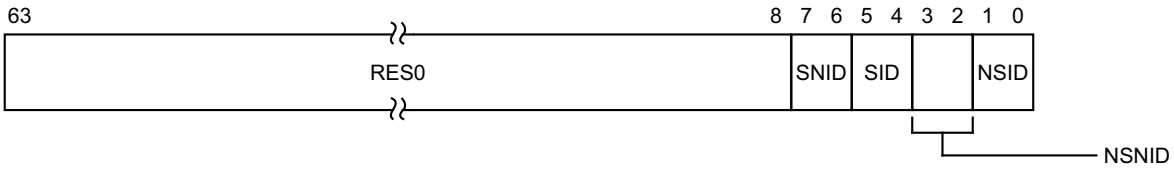
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGAUTHSTATUS_EL1 is a 64-bit register.

Field descriptions

The DBGAUTHSTATUS_EL1 bit assignments are:



Bits [63:8]

Reserved, RES0.

SNID, bits [7:6]

When ARMv8.4-Debug is implemented:

Secure non-invasive debug.

This field has the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise:

Secure non-invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.

`0b10` Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

SID, bits [5:4]

Secure invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.

`0b10` Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

All other values are reserved.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSNID, bits [3:2]

When ARMv8.4-Debug is implemented:

Non-secure non-invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0

`0b11` Implemented and enabled. EL3 is implemented or the Effective value of SCR_EL3.NS is 1.

All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.

`0b10` Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.

`0b10` Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

All other values are reserved.

Accessing the DBGAUTHSTATUS_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, DBGAUTHSTATUS_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0111	0b1110	0b110

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);

D13.3.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Configurations

AArch64 System register DBGBCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBCR<n>[31:0].

AArch64 System register DBGBCR<n>_EL1[31:0] is architecturally mapped to External register DBGBCR<n>_EL1[31:0].

If breakpoint n is not implemented then accesses to this register are UNDEFINED.

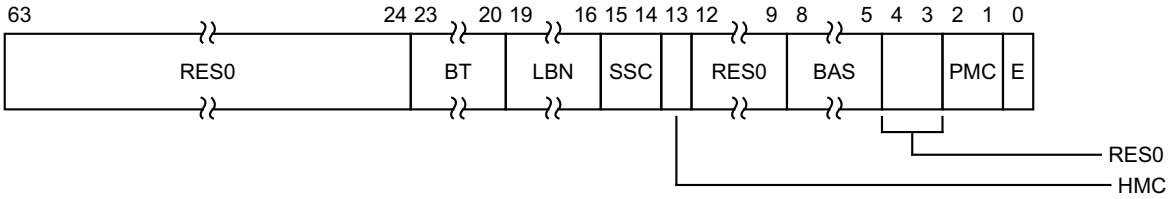
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGBCR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGBCR<n>_EL1 bit assignments are:



Bits [63:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

`0b0000` Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.

`0b0001` As `0b0000`, but linked to a Context matching breakpoint.

`0b0010` Unlinked Context ID match. When ARMv8.1-VHE is implemented, EL2 is using AArch64, and the Effective value of HCR_EL2.E2H is 1, if either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL2 value. Otherwise, DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL1 value

`0b0011` As `0b0010`, with linking enabled.

`0b0110` Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.

`0b0111` As `0b0110`, with linking enabled.

`0b1000` Unlinked VMID match. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.

`0b1001` As `0b1000`, with linking enabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1010` Unlinked VMID and Context ID match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.

`0b1011` As `0b1010`, with linking enabled.

`0b1100` Unlinked CONTEXTIDR_EL2 match. DBGBVR<n>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.

`0b1101` As `0b1100`, with linking enabled.

`0b1110` Unlinked Full Context ID match. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.ContextID2 is compared against CONTEXTIDR_EL2.

`0b1111` As `0b1110`, with linking enabled.

All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions.

For more information on the operation of the SSC, HMC, and PMC fields, and on the effect of programming this field to a reserved value, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422 and *Reserved DBGBCR<n>_EL1.BT values* on page D2-2427.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<n>_EL1.E is 0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields.

For more information on the operation of the SSC, HMC, and PMC fields, and the effect of programming the fields to a reserved set of values, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422 and *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values* on page D2-2427.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the SSC, bits [15:14] description.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64 only implementation, this field is reserved, RES1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The permitted values depend on the breakpoint type.

For Address match breakpoints, the permitted values are:

BAS	Match instruction at	Constraint for debuggers
0b0011	DBGBVR<n>_EL1	Use for T32 instructions
0b1100	DBGBVR<n>_EL1 + 2	Use for T32 instructions
0b1111	DBGBVR<n>_EL1	Use for A64 and A32 instructions

All other values are reserved. For more information, see *Reserved DBGBCR<n>_EL1.BAS values* on page D2-2428.

For more information on using the BAS field in address match breakpoints, see *Using the BAS field in Address Match breakpoints* on page G2-5641.

For Context matching breakpoints, this field is RES1 and ignored.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>_EL1.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable breakpoint DBGBVR<n>_EL1. Possible values are:

0b0 Breakpoint disabled.

0b1 Breakpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

D13.3.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1.

Configurations

AArch64 System register DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBVR<n>[31:0].

If the breakpoint is context-aware and EL2 is implemented then AArch64 System register DBGBVR<n>_EL1[63:32] is architecturally mapped to AArch32 System register DBGBXVR<n>[31:0]. Otherwise there is no System register access to DBGBVR<n>_EL1[63:32] from AArch32 state.

AArch64 System register DBGBVR<n>_EL1[63:0] is architecturally mapped to External register DBGBVR<n>_EL1[63:0].

If breakpoint n is not implemented then accesses to this register are UNDEFINED.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

How this register is interpreted depends on the value of DBGBCR<n>_EL1.BT.

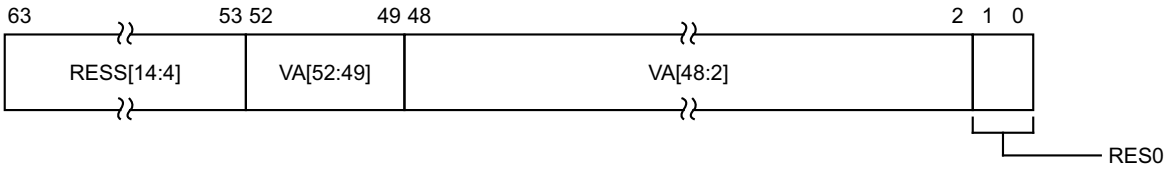
- When DBGBCR<n>_EL1.BT is `0b000x`, this register holds a virtual address.
- When DBGBCR<n>_EL1.BT is `0b001x`, `0b011x`, or `0b110x`, this register holds a Context ID.
- When DBGBCR<n>_EL1.BT is `0b100x`, this register holds a VMID.
- When DBGBCR<n>_EL1.BT is `0b101x`, this register holds a VMID and a Context ID.
- When DBGBCR<n>_EL1.BT is `0b111x`, this register holds two Context ID values.

For other values of DBGBCR<n>_EL1.BT, this register is RES0.

Field descriptions

The DBGBVR<n>_EL1 bit assignments are:

When DBGBCR<n>_EL1.BT == 0b000x:



RESS[14:4], bits [63:53]

Reserved, Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

It is IMPLEMENTATION DEFINED whether:

- Reads return the value of the most significant bit of the VA for every bit in this field.
- Reads return the last value written.

The PE ignores this field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

VA[52:49], bits [52:49]

When ARMv8.2-LVA is implemented:

Extension to VA[48:2]. See VA[48:2] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Extension to RESS[14:4]. See RESS[14:4] for more details.

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

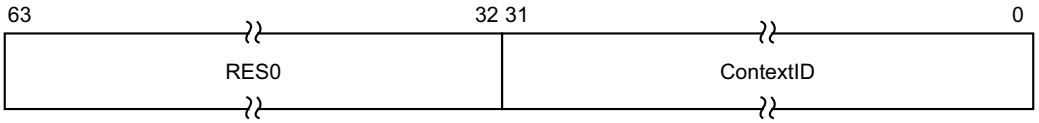
When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value. Otherwise, VA[52:49] are RESS.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b001x:



Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

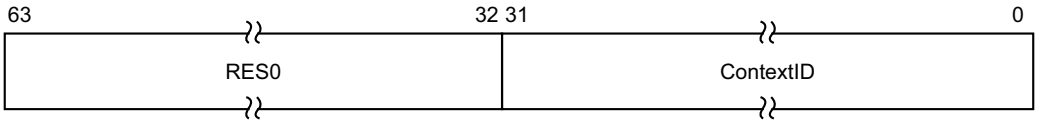
The value is compared against CONTEXTIDR_EL2 when ARMv8.1-VHE is implemented, HCR_EL2.E2H is 1, and either:

- The PE is executing at EL2.
- HCR_EL2.TGE is 1, the PE is executing at EL0, and EL2 is enabled in the current Security state.

Otherwise, the value is compared against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT == 0b011x:



Bits [63:32]

Reserved, RES0.

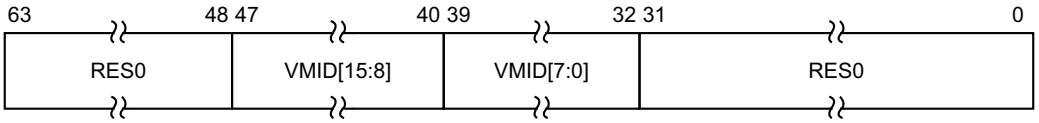
ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When DBGBCR<n>_EL1.BT == 0b100x and HaveEL(EL2):



Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When ARMv8.1-VMID16 is implemented:

Extension to VMID[7:0]. See VMID[7:0] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

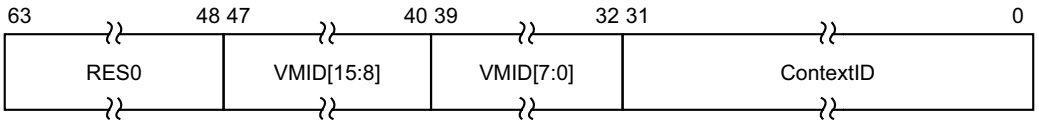
- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b101x and HaveEL(EL2):



Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When ARMv8.1-VMID16 is implemented:

Extension to VMID[7:0]. See VMID[7:0] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

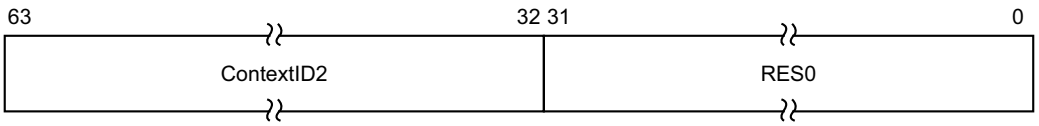
On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT == 0b110x and HaveEL(EL2):



ContextID2, bits [63:32]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

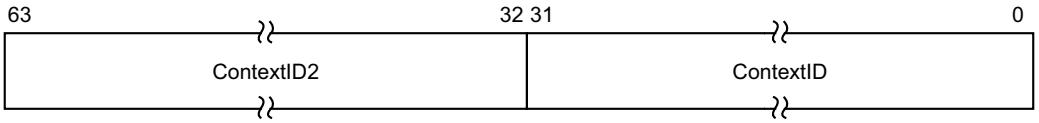
Otherwise:

Reserved, RES0.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b111x, HaveEL(EL2) and ARMv8.1-VHE is implemented:



ContextID2, bits [63:32]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGBVR<n>_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET_EL1 register.

Configurations

AArch64 System register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMCLR[31:0].

AArch64 System register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to External register DBGCLAIMCLR_EL1[31:0].

An implementation must include 8 CLAIM tag bits.

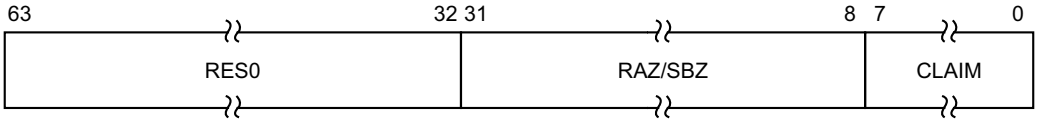
This register is in the Cold reset domain. See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset.

Attributes

DBGCLAIMCLR_EL1 is a 64-bit register.

Field descriptions

The DBGCLAIMCLR_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

On a Cold reset, this field resets to `0`.

Accessing the DBGCLAIMCLR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D13.3.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR_EL1 register.

Configurations

AArch64 System register DBGCLAIMSET_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMSET[31:0].

AArch64 System register DBGCLAIMSET_EL1[31:0] is architecturally mapped to External register DBGCLAIMSET_EL1[31:0].

An implementation must include 8 CLAIM tag bits.

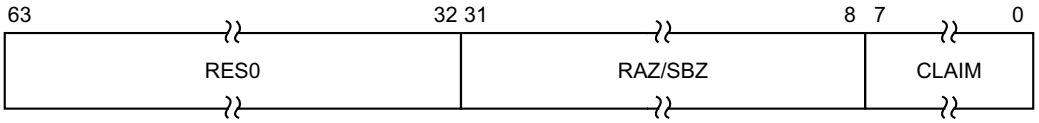
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGCLAIMSET_EL1 is a 64-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

Accessing the DBGCLAIMSET_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.6 DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

Purpose

Transfers 64 bits of data between the PE and an external debugger. Can transfer both ways using only a single register.

Configurations

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to External register DBGDTRRX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0] when written.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0] when written.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0] when read.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to External register DBGDTRTX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[63:32] is architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to External register DBGDTRRX_EL0[31:0] when read.

AArch64 System register DBGDTR_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0] when read.

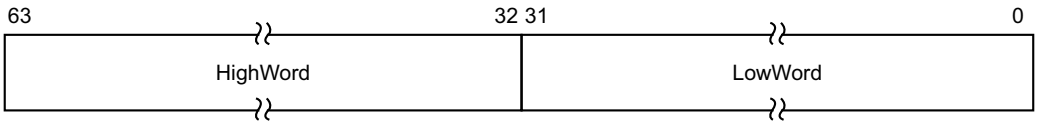
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGDTR_EL0 is a 64-bit register.

Field descriptions

The DBGDTR_EL0 bit assignments are:



HighWord, bits [63:32]

Writes to this register set DTRRX to the value in this field and do not change RXfull.

Reads of this register:

- If RXfull is set to 1, return the last value written to DTRTX.
- If RXfull is set to 0, return an UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

After the read, RXfull is cleared to 0.

LowWord, bits [31:0]

Writes to this register set DTRTX to the value in this field and set TXfull to 1.

Reads of this register:

- If RXfull is set to 1, return the last value written to DTRRX.
- If RXfull is set to 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

Accessing the DBGDTR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.7 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

Configurations

AArch64 System register DBGDTRRX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0].

AArch64 System register DBGDTRRX_EL0[31:0] is architecturally mapped to External register DBGDTRRX_EL0[31:0].

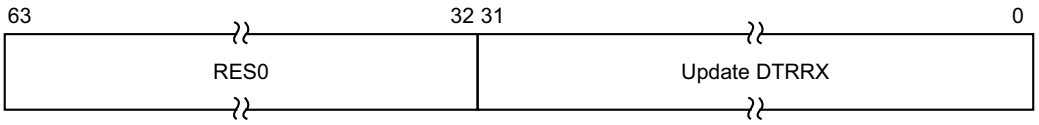
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGDTRRX_EL0 is a 64-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

Bits [31:0]

Update DTRRX.

Reads of this register:

- If RXfull is set to 1, return the last value written to DTRRX.
- If RXfull is set to 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

D13.3.8 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

Configurations

AArch64 System register DBGDTRTX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0].

AArch64 System register DBGDTRTX_EL0[31:0] is architecturally mapped to External register DBGDTRTX_EL0[31:0].

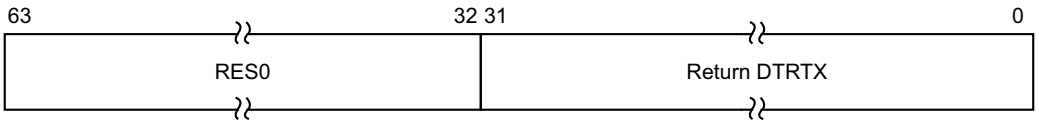
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGDTRTX_EL0 is a 64-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

Bits [31:0]

Return DTRTX.

Writes to this register:

- If TXfull is set to 1, set DTRRX and DTRTX to UNKNOWN.
- If TXfull is set to 0, update the value in DTRTX.

After the write, TXfull is set to 1.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

D13.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

Configurations

AArch64 System register DBGPRCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGPRCR[31:0].

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

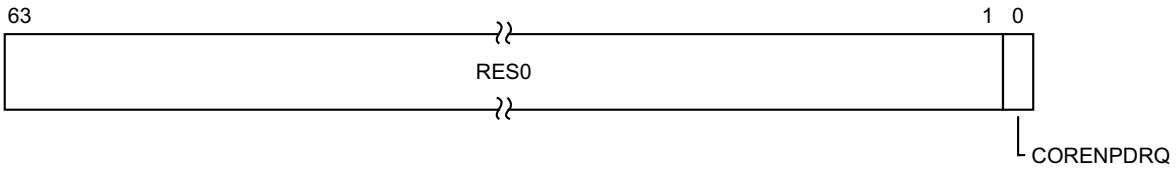
This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGPRCR_EL1 is a 64-bit register.

Field descriptions

The DBGPRCR_EL1 bit assignments are:



Bits [63:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

`0b0` If the system responds to a powerdown request, it powers down Core power domain.

`0b1` If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see *Core power domain power states* on page H6-6808.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

Accessing the DBGPRCR_EL1

D13.3.10 DBGVCR32_EL2, Debug Vector Catch Register

The DBGVCR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register DBGVCR from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configurations

AArch64 System register DBGVCR32_EL2[31:0] is architecturally mapped to AArch32 System register DBGVCR[31:0].

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

This register has no effect if EL2 is not enabled in the current Security state.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

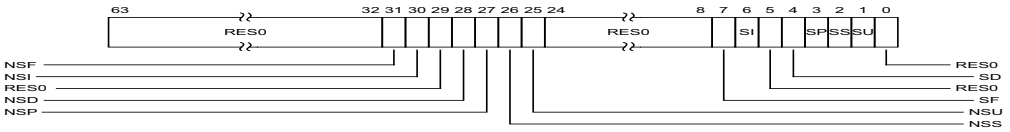
Attributes

DBGVCR32_EL2 is a 64-bit register.

Field descriptions

The DBGVCR32_EL2 bit assignments are:

When HaveEL(EL3) and !ELUsingAArch32(EL3):



Bits [63:32]

Reserved, RES0.

NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is `0x1C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is `0x18`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is `0x04`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [24:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is `0x1C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is `0x18`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is `0x10`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is `0x08`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

The exception vector offset is `0x04`.

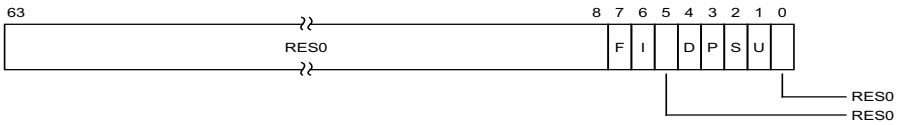
On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [0]

Reserved, RES0.

When !HaveEL(EL3):



Bits [63:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.

The exception vector offset is `0x1C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [6]

IRQ vector catch enable.

The exception vector offset is `0x18`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

D, bit [4]

Data Abort vector catch enable.

The exception vector offset is `0x10`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P, bit [3]

Prefetch Abort vector catch enable.

The exception vector offset `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [2]

Supervisor Call (SVC) vector catch enable.

The exception vector offset is `0x08`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [1]

Undefined Instruction vector catch enable.

The exception vector offset is `0x04`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

D13.3.11 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

Configurations

AArch64 System register DBGWCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWCR<n>[31:0].

AArch64 System register DBGWCR<n>_EL1[31:0] is architecturally mapped to External register DBGWCR<n>_EL1[31:0].

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

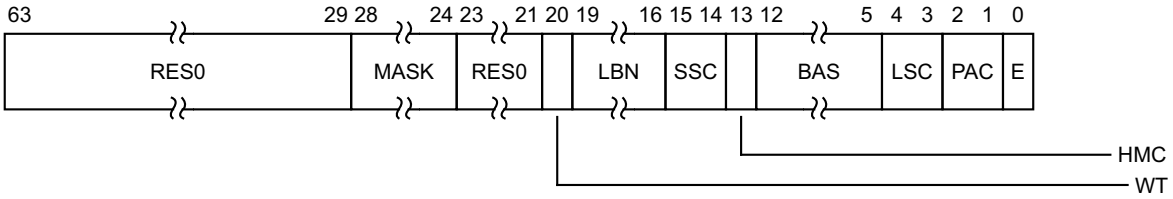
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGWCR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWCR<n>_EL1 bit assignments are:



Bits [63:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`0b00000` No mask.

`0b00001` Reserved.

`0b00010` Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from `0b00011` masking 3 address bits (`0x00000007` mask for address) to `0b11111` masking 31 address bits (`0x7FFFFFFF` mask for address).

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [23:21]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

WT, bit [20]

Watchpoint type. Possible values are:

`0b0` Unlinked data address match.

`0b1` Linked data address match.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422, and *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values* on page D2-2427.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page D2-2433.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1 + 1
xxxxx1xx	Match byte at DBGWVR<n>_EL1 + 2
xxxx1xxx	Match byte at DBGWVR<n>_EL1 + 3

In cases where DBGWVR<n>_EL1 addresses a double-word:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1 + 4
xx1xxxxx	Match byte at DBGWVR<n>_EL1 + 5
x1xxxxxx	Match byte at DBGWVR<n>_EL1 + 6
1xxxxxxx	Match byte at DBGWVR<n>_EL1 + 7

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] are used and BAS[7:4] are ignored. Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The valid values for BAS are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See *Reserved DBGWCR<n>_EL1.BAS values* on page D2-2442.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

`0b01` Match instructions that load from a watchpointed address.

`0b10` Match instructions that store to a watchpointed address.

`0b11` Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page D2-2433.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint n. Possible values are:

`0b0` Watchpoint disabled.

`0b1` Watchpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

D13.3.12 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1.

Configurations

AArch64 System register DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWVR<n>[31:0].

AArch64 System register DBGWVR<n>_EL1[63:0] is architecturally mapped to External register DBGWVR<n>_EL1[63:0].

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

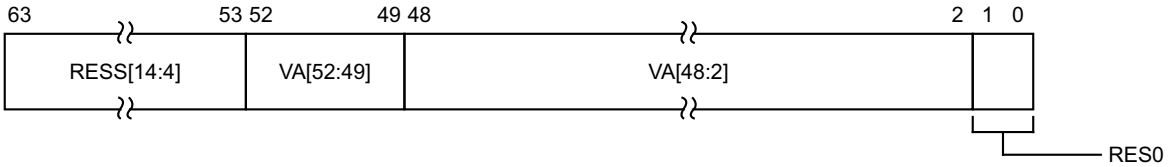
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:



RESS[14:4], bits [63:53]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA[52:49], bits [52:49]

When ARMv8.2-LVA is implemented:

Extension to VA[48:2]. See VA[48:2] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Extension to RESS[14:4]. See RESS[14:4] for more details.

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value. Otherwise, VA[52:49] are RESS.

Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

D13.3.13 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

Configurations

AArch64 System register DLR_EL0[31:0] is architecturally mapped to AArch32 System register DLR[31:0].

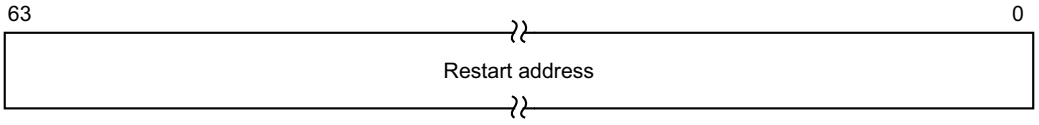
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions

The DLR_EL0 bit assignments are:



Bits [63:0]

Restart address.

Accessing the DLR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, DLR_EL0

D13.3.14 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved process state for Debug state. On entering Debug state, PSTATE information is written to this register. On exiting Debug state, values are copied from this register to PSTATE.

Configurations

AArch64 System register DSPSR_EL0[31:0] is architecturally mapped to AArch32 System register DSPSR[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

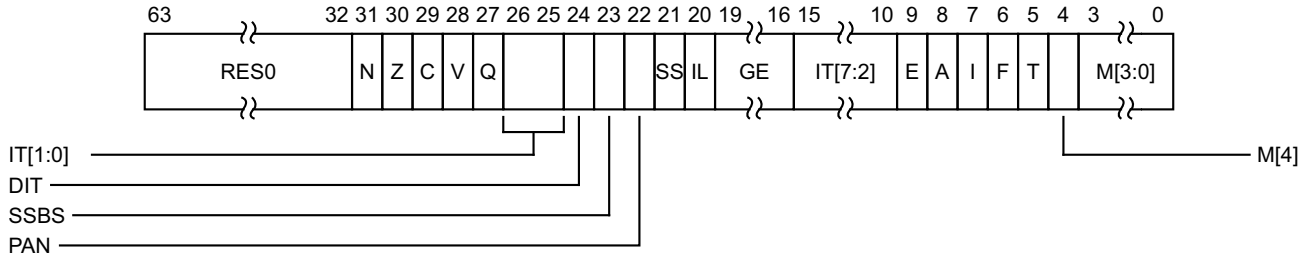
Attributes

DSPSR_EL0 is a 64-bit register.

Field descriptions

The DSPSR_EL0 bit assignments are:

When exiting Debug state to AArch32 state:



Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Copied to PSTATE.N on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Copied to PSTATE.Z on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Copied to PSTATE.C on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Copied to PSTATE.V on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Copied to PSTATE.Q on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IT[1:0], bits [26:25]

If-Then. Copied to PSTATE.IT[1:0] on exiting Debug state.

On exiting Debug state DSPSR_EL0.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Copied to PSTATE.DIT on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSBS, bit [23]

When ARMv8.0-SSBS is implemented:

Speculative Store Bypass. Copied to PSTATE.SSBS on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Copied to PSTATE.PAN on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Copied to PSTATE.SS on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Copied to PSTATE.IL on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Copied to PSTATE.GE on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Copied to PSTATE.IT[7:2] on exiting Debug state.

DSPSR_EL0.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

E, bit [9]

Endianness. Copied to PSTATE.E on exiting Debug state.

If the implementation does not support big-endian operation, DSPSR_EL0.E is RES0. If the implementation does not support little-endian operation, DSPSR_EL0.E is RES1. On exiting Debug state, if the implementation does not support big-endian operation at the Exception level being returned to, DSPSR_EL0.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, DSPSR_EL0.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Copied to PSTATE.A on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Copied to PSTATE.I on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Copied to PSTATE.F on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Copied to PSTATE.T on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

M[4], bit [4]

Execution state. Copied to PSTATE.nRW on exiting Debug state.

`0b1` AArch32 execution state.

This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch32 Mode. Copied to PSTATE.M[3:0] on exiting Debug state.

`0b0000` User.

`0b0001` FIQ.

`0b0010` IRQ.

`0b0011` Supervisor.

`0b0110` Monitor.

`0b0111` Abort.

`0b1010` Hyp.

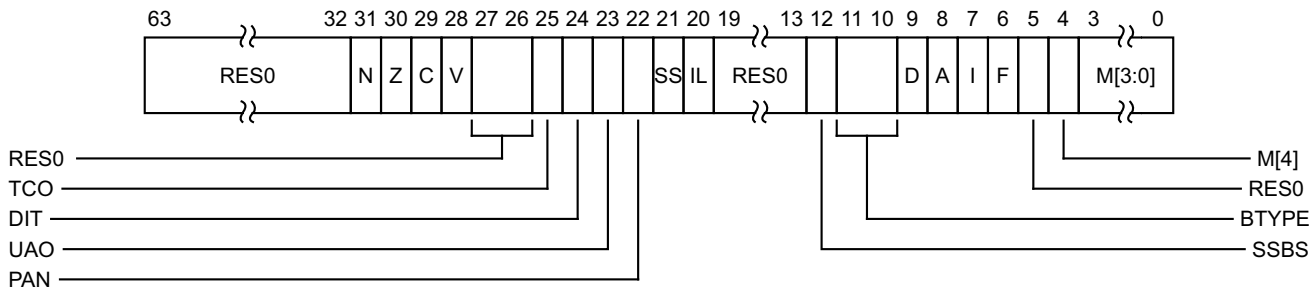
`0b1011` Undefined.

`0b1111` System.

Other values are reserved. If DSPSR_EL0.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2304.

This field resets to an architecturally UNKNOWN value.

When entering Debug state from AArch64 state and exiting Debug state to AArch64 state:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on entering Debug state, and copied to PSTATE.N on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on entering Debug state, and copied to PSTATE.Z on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on entering Debug state, and copied to PSTATE.C on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on entering Debug state, and copied to PSTATE.V on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Bits [27:26]

Reserved, RES0.

TCO, bit [25]

When ARMv8.5-MemTag is implemented:

Tag Check Override. Set to the value of PSTATE.TCO on entering Debug state, and copied to PSTATE.TCO on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DIT, bit [24]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When ARMv8.2-UAO is implemented:

User Access Override. Set to the value of PSTATE.UAO on entering Debug state, and copied to PSTATE.UAO on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Non-Confidential

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on entering Debug state, and conditionally copied to PSTATE.SS on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on entering Debug state, and copied to PSTATE.IL on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When ARMv8.0-SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on entering Debug state, and copied to PSTATE.SSBS on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BTYPE, bits [11:10]

When ARMv8.5-BTI is implemented:

Branch Type Indicator. Set to the value of PSTATE.BTYPE on entering Debug state, and copied to PSTATE.BTYPE on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on entering Debug state, and copied to PSTATE.D on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on entering Debug state, and copied to PSTATE.A on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on entering Debug state, and copied to PSTATE.I on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on entering Debug state, and copied to PSTATE.F on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to `0b0`, the value of PSTATE.nRW, on entering Debug state from AArch64 state, and copied to PSTATE.nRW on exiting Debug state.

`0b0` AArch64 execution state.

If AArch32 is not supported at any Exception level, this bit is RES0.

This field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

`0b0000` EL0t.

`0b0100` EL1t.

`0b0101` EL1h.

`0b1000` EL2t.

`0b1001` EL2h.

`0b1100` EL3t.

`0b1101` EL3h.

Other values are reserved. If DSPSR_EL0.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in *Illegal return events from AArch64 state* on page D1-2304.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on entering Debug state and copied to PSTATE.EL on exiting Debug state.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on entering Debug state and copied to PSTATE.SP on exiting Debug state

This field resets to an architecturally UNKNOWN value.

Accessing the DSPSR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, DSPSR_EL0

D13.3.15 MDCCINT_EL1, Monitor DCC Interrupt Enable Register

The MDCCINT_EL1 characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

Configurations

AArch64 System register MDCCINT_EL1[31:0] is architecturally mapped to AArch32 System register DBGDCCINT[31:0].

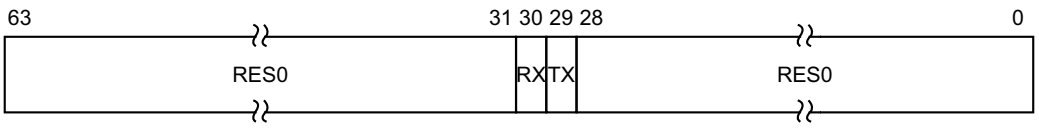
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDCCINT_EL1 is a 64-bit register.

Field descriptions

The MDCCINT_EL1 bit assignments are:



Bits [63:31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common **COMMIRQ** interrupt request to be signaled based on the DCC status flags.

`0b0` No interrupt request generated by DTRRX.

`0b1` Interrupt request will be generated on RXfull == 1.

If legacy **COMMRX** and **COMMTX** signals are implemented, then these are not affected by the value of this bit.

On a Warm reset, this field resets to `0`.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common **COMMIRQ** interrupt request to be signaled based on the DCC status flags.

`0b0` No interrupt request generated by DTRTX.

`0b1` Interrupt request will be generated on TXfull == 0.

If legacy **COMMRX** and **COMMTX** signals are implemented, then these are not affected by the value of this bit.

On a Warm reset, this field resets to `0`.

Bits [28:0]

Reserved, RES0.

Accessing the MDCCINT_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.16 MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

Purpose

Read-only register containing control status flags for the DCC.

Configurations

AArch64 System register MDCCSR_EL0[30:29] is architecturally mapped to External register EDSCR[30:29].

AArch64 System register MDCCSR_EL0[30:29] is architecturally mapped to AArch32 System register DBGDSCRint[30:29].

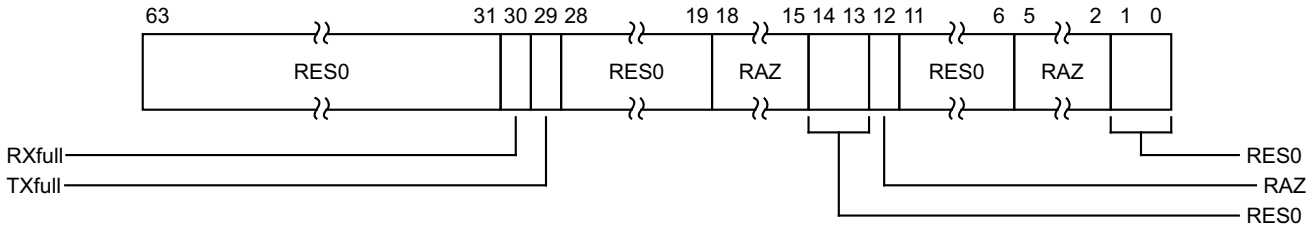
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDCCSR_EL0 is a 64-bit register.

Field descriptions

The MDCCSR_EL0 bit assignments are:



Bits [63:31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the EDSCR.

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the EDSCR.

D13.3.17 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

Purpose

Provides EL2 configuration options for self-hosted debug and the Performance Monitors Extension.

Configurations

AArch64 System register MDCR_EL2[31:0] is architecturally mapped to AArch32 System register HDCR[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

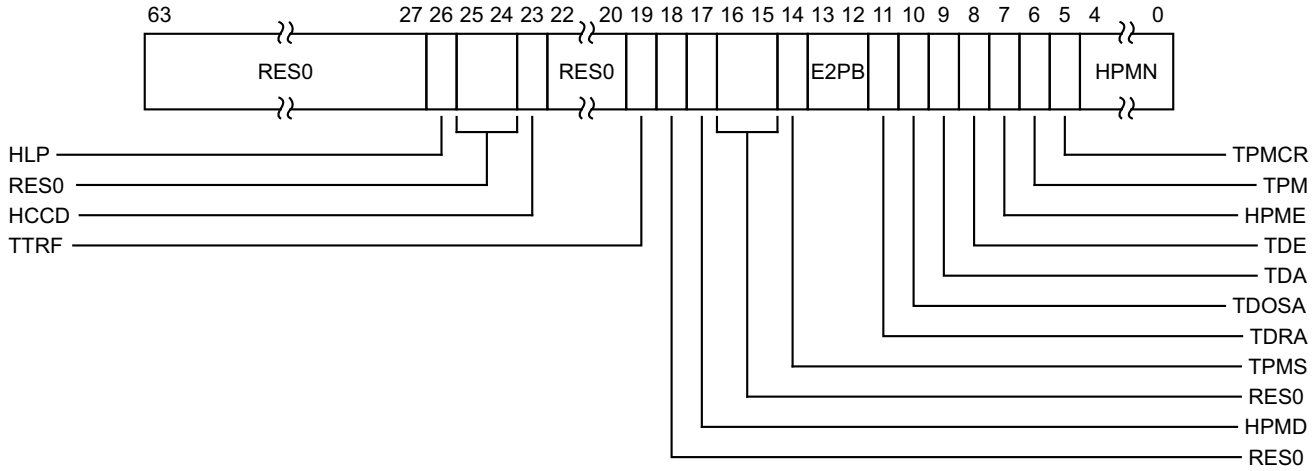
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDCR_EL2 is a 64-bit register.

Field descriptions

The MDCR_EL2 bit assignments are:



Bits [63:27]

Reserved, RES0.

HLP, bit [26]

When ARMv8.5-PMU is implemented:

Hypervisor Long event counter enable. Determines when unsigned overflow is recorded by a counter overflow bit.

`0b0` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>_EL0[31:0].

`0b1` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>_EL0[63:0].

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If MDCR_EL2.HPMN is less than PMCR_EL0.N or PMCR.N, this bit affects the operation of event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] or [MDCR_EL2.HPMN..(PMCR.N-1)]. Otherwise this bit has no effect on the operation of the event counters.

Note

The effect of MDCR_EL2.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state.

For more information see the description of the MDCR_EL2.HPMN field.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [25:24]

Reserved, RES0.

HCCD, bit [23]

When ARMv8.5-PMU is implemented:

Hypervisor Cycle Counter Disable. Prohibits PMCCNTR_EL0 from counting at EL2.

`0b0` Cycle counting by PMCCNTR_EL0 is not affected by this bit.

`0b1` Cycle counting by PMCCNTR_EL0 is prohibited at EL2.

This bit does not affect the CPU_CYCLES event or any other event that counts cycles.

This field resets to `0`.

Otherwise:

Reserved, RES0.

Bits [22:20]

Reserved, RES0.

TTRF, bit [19]

When ARMv8.4-Trace is implemented:

Traps use of the Trace Filter Control registers at EL1 to EL2, as follows:

- Access to TRFCR_EL1 is trapped to EL2, reported using EC syndrome value `0x18`.
- Access to TRFCR is trapped to EL2, reported using EC syndrome value `0x03`.

`0b0` Accesses to TRFCR_EL1 and TRFCR at EL1 are not affected by this control.

`0b1` Accesses to TRFCR_EL1 and TRFCR at EL1 generate a trap exception to EL2 when EL2 is enabled in the current Security state.

Otherwise:

Reserved, RES0.

Bit [18]

Reserved, RES0.

HPMD, bit [17]

When ARMv8.1-PMU is implemented:

Guest Performance Monitors Disable. This control prohibits event counting at EL2.

`0b0` Event counting allowed at EL2.

`0b1` Event counting prohibited at EL2.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If ARMv8.2-Debug is not implemented, event counting is prohibited unless enabled by the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().

This control applies only to:

- The event counters in the range [0..(MDCR_EL2.HPMN-1)].
- If PMCR_EL0.DP is set to 1, PMCCNTR_EL0.

The other event counters are unaffected, and when PMCR_EL0.DP is set to 0, PMCCNTR_EL0 is unaffected.

On a Warm reset, this field resets to `0`.

Otherwise:

Reserved, RES0.

Bits [16:15]

Reserved, RES0.

TPMS, bit [14]

When SPE is implemented:

Trap Performance Monitor Sampling. When EL2 is enabled in the current Security state, this field controls access to Statistical Profiling control registers from EL1.

`0b0` Do not trap Statistical Profiling controls to EL2.

`0b1` Accesses to Statistical Profiling controls at EL1 generate a Trap exception to EL2 when EL2 is enabled in the current Security state.

The Statistical Profiling control registers trapped by this control are: PMSCR_EL1, PMSEVFR_EL1, PMSFCR_EL1, PMSICR_EL1, PMSIDR_EL1, PMSIRR_EL1, and PMSLATFR_EL1.

Otherwise:

Reserved, RES0.

E2PB, bits [13:12]

When SPE is implemented:

EL2 Profiling Buffer. When EL2 is enabled in the current Security state, this field controls the owning translation regime and access to Profiling Buffer control registers from EL1.

`0b00` Profiling Buffer uses the EL2 stage 1 translation regime. Accesses to Profiling Buffer controls at EL1 generate a Trap exception to EL2 when EL2 is enabled in the current Security state.

`0b10` Profiling Buffer uses the EL1&0 stage 1 translation regime. Accesses to Profiling Buffer controls at EL1 generate a Trap exception to EL2 when EL2 is enabled in the current Security state.

`0b11` Profiling Buffer uses the EL1&0 stage 1 translation regime. Accesses to Profiling Buffer controls at EL1 are not trapped.

All other values are reserved.

The Profiling Buffer control registers trapped by this control are: PMBLIMITR_EL1, PMBPTR_EL1, and PMBSR_EL1.

If EL2 is not implemented, or is disabled in the current Security State, the PE behaves as if E2PB == `0b11`, other than for a direct read of the register.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TDRA, bit [11]

Trap Debug ROM Address register access. Traps System register accesses to the Debug ROM registers to EL2 when EL2 is enabled in the current Security state as follows:

- If EL1 is using AArch64 state, accesses to MDRAR_EL1 are trapped to EL2, reported using EC syndrome value `0x18`.
- If EL0 or EL1 is using AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x05` and MRRC or MCRR accesses are trapped to EL2, reported using EC syndrome value `0x0C`:
  - DBGDRAR, DBGDSAR.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2 when EL2 is enabled in the current Security state, unless it is trapped by DBGDSCRext.UDCCdis or MDSCR_EL1.TDCC.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDOSA, bit [10]

When ARMv8.0-DoubleLock is implemented:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x18`:
  - OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, and DBGPRCR_EL1.
  - Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.
- In AArch32 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x05`:
  - DBGOSLSR, DBGOSLAR, DBGOSDLR, and DBGPRCR.
  - Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL1 System register accesses to the powerdown debug registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x18`:
  - OSLAR_EL1, OSLSR_EL1, and DBGPRCR_EL1.
  - Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.
- In AArch32 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x05`:
  - DBGOSLSR, DBGOSLAR, and DBGPRCR.
  - Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

It is IMPLEMENTATION DEFINED whether accesses to OSDLR_EL1 are trapped and DBGOSDLR are trapped.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL1 System register accesses to the powerdown debug registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDA, bit [9]

Trap Debug Access. Traps EL0 and EL1 System register accesses to debug System registers that are not trapped by MDCR_EL2.TDRA or MDCR_EL2.TDOSA, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2 reported using EC syndrome value `0x18`:
  - MDCCSR_EL0, MDCCINT_EL1, OSDTRRX_EL1, MDSCR_EL1, OSDTRTX_EL1, OSECCR_EL1, DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, DBGWCR<n>_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, DBGAUTHSTATUS_EL1.
  - When not in Debug state, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x05.
  - DBGDIDR, DBGDSCRint, DBGDCCINT, DBGWFAR, DBGVCR, DBGDSCRext, DBGDTRTXext, DBGDTRRXext, DBGBVR<n>, DBGBCR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, DBGOSECCR.
  - When not in Debug state, DBGDTRRXint and DBGDTRTXint.
- In AArch32 state, STC accesses to DBGDTRRXint and LDC accesses to DBGDTRTXint are trapped to EL2, reported using EC syndrome value 0x06.

0b0 This control does not cause any instructions to be trapped.

0b1 EL0 or EL1 System register accesses to the debug registers are trapped from both Execution states to EL2 when EL2 is enabled in the current Security state, unless the access generates a higher priority exception.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

Traps of AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0 are ignored in Debug state.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1
- HCR_EL2.TGE == 1

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDE, bit [8]

Trap Debug exceptions.

0b0 This control has no effect on the routing of debug exceptions, and has no effect on accesses to debug registers.

0b1 Debug exceptions generated at EL1 or EL0 are routed to EL2 when EL2 is enabled in the current Security state. The MDCR_EL2.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

This field is treated as being 1 for all purposes other than a direct read when HCR_EL2.TGE == 1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

HPME, bit [7]

When PMUv3 is implemented:

[MDCR_EL2.HPMN..(N-1)] event counters enable.

0b0 Event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] are disabled.

0b1 Event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] are enabled by PMCNTENSET_EL0.

If MDCR_EL2.HPMN is less than PMCR_EL0.N or PMCR.N, the event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)] or [HDCR.HPMN..(PMCR.N-1)], are enabled and disabled by this bit. Otherwise this bit has no effect on the operation of the event counters.

Note

The effect of MDCR_EL2.HPMN on the operation of this bit applies regardless of whether EL2 is enabled in the current Security state.

For more information see the description of the HPMN field.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TPM, bit [6]

When PMUv3 is implemented:

Trap Performance Monitors accesses. Traps EL0 and EL1 accesses to all Performance Monitor registers to EL2 when EL2 is enabled in the current Security state, from both Execution states, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x18`:
  - PMCR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMOVSCLR_EL0, PMSWINC_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMXEVCNTR_EL0, PMUSERENR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 and reported using EC syndrome value `0x03`, MRRC or MCRR accesses are trapped to EL2 and reported using EC syndrome value `0x04`:
  - PMCR, PMCNTENSET, PMCNTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.
- If ARMv8.4-PMU is implemented, in AArch64 state, PMMIR_EL1 and in AArch32 state, PMMIR.
- If ARMv8.1-PMU is implemented, in AArch32 state, PMCEID2 and PMCEID3.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL0 and EL1 accesses to all Performance Monitor registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TPMCR, bit [5]

When PMUv3 is implemented:

Trap PMCR_EL0 or PMCR accesses. Traps EL0 and EL1 accesses to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to PMCR_EL0 are trapped to EL2, reported using EC syndrome value `0x18`.
- In AArch32 state, accesses to PMCR are trapped to EL2, reported using EC syndrome value `0x03`.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL0 and EL1 accesses to the PMCR_EL0 or PMCR are trapped to EL2 when EL2 is enabled in the current Security state, unless it is trapped by PMUSERENR.EN or PMUSERENR_EL0.EN.

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

HPMN, bits [4:0]

When PMUv3 is implemented:

Defines the number of event counters that are accessible from EL3, EL2, EL1, and from EL0 if permitted.

If HPMN is less than PMCR_EL0.N, HPMN divides the Performance Monitors into two ranges: [0..(HPMN-1)] and [HPMN..(PMCR_EL0.N-1)].

For an event counter in the range [0..(HPMN-1)]:

- The counter is accessible from EL3, EL2, and EL1, and from EL0 if permitted by PMUSERENR_EL0 or PMUSERENR.
- If ARMv8.5-PMU is implemented, PMCR_EL0.LP or PMCR.LP determines whether the counter overflow flag is set on unsigned overflow of PMEVCNTR<n>_EL0[31:0] or PMEVCNTR<n>_EL0[63:0].
- The counter is enabled by PMCR_EL0.E or PMCR.E and bit <n> of PMCNTENSET_EL0.

Note

If HPMN is equal to PMCR_EL0.N, this applies to all event counters.

If HPMN is less than PMCR_EL0.N, for an event counter in the range [HPMN..(PMCR_EL0.N-1)]:

- The counter is accessible from EL2 and EL3.
- If ARMv8.4-SecEL2 is disabled or is not implemented, the counter is also accessible from Secure EL1 and from Secure EL0 if permitted by PMUSERENR_EL0.
- If ARMv8.5-PMU is implemented, MDCR_EL2.HLP or HDCR.HLP determines whether the counter overflow flag is set on unsigned overflow of PMEVCNTR<n>_EL0[31:0] or PMEVCNTR<n>_EL0[63:0].
- The counter is enabled by MDCR_EL2.HPME or HDCR.HPME and bit <n> of PMCNTENSET_EL0.

If this field is set to 0, or to a value larger than PMCR_EL0.N, then the following CONSTRAINED UNPREDICTABLE behaviors apply:

- The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 and EL3 use. That is, the PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN non-zero value less than or equal to PMCR_EL0.N.
  - All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

On a Warm reset, this field resets to the value in PMCR_EL0.N.

Otherwise:

Reserved, RES0.

Accessing the MDCR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.18 MDCR_EL3, Monitor Debug Configuration Register (EL3)

The MDCR_EL3 characteristics are:

Purpose

Provides EL3 configuration options for self-hosted debug and the Performance Monitors Extension.

Configurations

AArch64 System register MDCR_EL3[31:0] can be mapped to AArch32 System register SDCR[31:0], but this is not architecturally mandated.

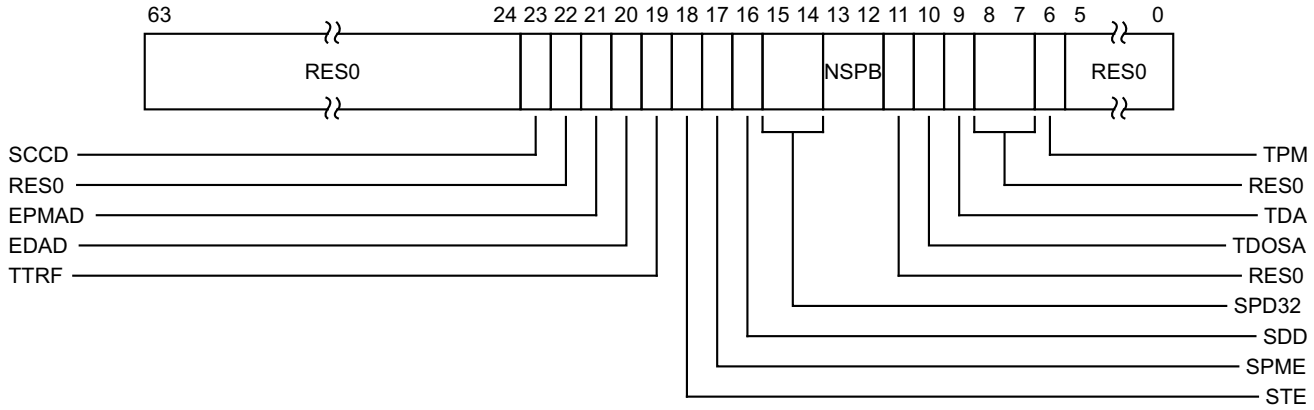
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDCR_EL3 is a 64-bit register.

Field descriptions

The MDCR_EL3 bit assignments are:



Bits [63:24]

Reserved, RES0.

SCCD, bit [23]

When ARMv8.5-PMU is implemented:

Secure Cycle Counter Disable. Prohibits PMCCNTR_EL0 from counting in Secure state.

`0b0` Cycle counting by PMCCNTR_EL0 is not affected by this bit.

`0b1` Cycle counting by PMCCNTR_EL0 is prohibited in Secure state.

This bit does not affect the CPU_CYCLES event or any other event that counts cycles.

This field resets to `0`.

Otherwise:

Reserved, RES0.

Bit [22]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EPMAD, bit [21]

When ARMv8.4-Debug is implemented and PMUv3 is implemented:

External Performance Monitors Non-secure Access Disable. Controls Non-secure access to Performance Monitor registers by an external debugger.

`0b0` Non-secure access to Performance Monitor registers from external debugger is permitted.

`0b1` Non-secure access to Performance Monitor registers from external debugger is not permitted.

If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.

Otherwise, if EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this bit is `0b1`.

On a Warm reset, this field resets to `0`.

When PMUv3 is implemented:

External Performance Monitors Access Disable. Controls access to Performance Monitor registers by an external debugger.

`0b0` Access to Performance Monitor registers from external debugger is permitted.

`0b1` Access to Performance Monitor registers from external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.

Otherwise, if EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this bit is `0b1`.

On a Warm reset, this field resets to `0`.

Otherwise:

Reserved, RES0.

EDAD, bit [20]

When ARMv8.4-Debug is implemented:

External Debug Non-secure Access Disable. Controls Non-secure access to breakpoint, watchpoint, and OSLAR_EL1 registers by an external debugger.

`0b0` Non-secure access to debug registers from external debugger is permitted.

`0b1` Non-secure access to breakpoint and watchpoint registers, and OSLAR_EL1 from external debugger is not permitted.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this field is `0b1`.

On a Warm reset, this field resets to `0`.

When ARMv8.2-Debug is implemented:

External Debug Access Disable. Controls access to breakpoint, watchpoint, and OSLAR_EL1 registers by an external debugger.

`0b0` Access to debug registers, and to OSLAR_EL1 from external debugger is permitted.

`0b1` Access to breakpoint and watchpoint registers, and to OSLAR_EL1 from external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this field is `0b1`.

On a Warm reset, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

External Debug Access disable. Controls access to breakpoint, watchpoint, and optionally OSLAR_EL1 registers by an external debugger.

`0b0` Access to debug registers from external debugger is permitted.

`0b1` Access to breakpoint and watchpoint registers from an external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

It is IMPLEMENTATION DEFINED whether access to the OSLAR_EL1 register from an external debugger is permitted or not permitted.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this field is `0b1`.

On a Warm reset, this field resets to `0`.

TTRF, bit [19]

When ARMv8.4-Trace is implemented:

Trap Trace Filter controls. Traps use of the Trace Filter control registers at EL2 and EL1 to EL3.

The Trace Filter registers trapped by this control are:

- TRFCR_EL2, TRFCR_EL12, TRFCR_EL1, reported using EC syndrome value `0x18`.
- HTRFCR and TRFCR, reported using EC syndrome value `0x03`.

`0b0` Accesses to Trace Filter registers at EL2 and EL1 are not affected by this bit.

`0b1` Accesses to Trace Filter registers at EL2 and EL1 generate a Trap exception to EL3, unless the access generates a higher priority exception.

Otherwise:

Reserved, RES0.

STE, bit [18]

When ARMv8.4-Trace is implemented:

Secure Trace enable. Enables tracing in Secure state.

`0b0` Trace prohibited in Secure state unless overridden by the IMPLEMENTATION DEFINED authentication interface.

`0b1` Trace in Secure state is not affected by this bit.

This bit also controls the level of authentication required by an external debugger to enable external tracing. See *Register controls to enable self-hosted trace* on page D3-2462. If EL3 is not implemented the Effective value of SCR_EL3.NS is `0b0`, the Effective value of this bit is `0b1`.

On a Warm reset, this field resets to `0`.

Otherwise:

Reserved, RES0.

SPME, bit [17]

When ARMv8.2-Debug is implemented and PMUv3 is implemented:

Secure Performance Monitors enable. This allows event counting in Secure state.

`0b0` Event counting prohibited in Secure state.

`0b1` Event counting in Secure state not affected by this bit.

If EL3 is not implemented the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this bit is `0b1`.

This field resets to `0`.

When PMUv3 is implemented:

Secure Performance Monitors enable. This allows event counting in Secure state.

`0b0` Event counting prohibited in Secure state, unless ExternalSecureNoninvasiveDebugEnabled() is TRUE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` Event counting in Secure state not affected by this bit.

If EL3 is not implemented the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this bit is `0b1`.

This field resets to `0`.

Otherwise:

Reserved, RES0.

SDD, bit [16]

AArch64 Secure Self-hosted invasive debug disable. Disables Software debug exceptions in Secure state, other than Breakpoint Instruction exceptions.

`0b0` Debug exceptions from Secure EL0 are enabled, and debug exceptions from Secure EL1 are not affected by this bit.

`0b1` Debug exceptions, other than Breakpoint Instruction exceptions, are disabled from all Exception levels in Secure state.

The SDD bit is ignored unless both of the following are true:

- The PE is in Secure state.
- The Effective value of SCR_EL3.RW is `0b1`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SPD32, bits [15:14]

AArch32 Secure self-hosted privileged debug. Enables or disables debug exceptions from Secure EL1 using AArch32, other than Breakpoint Instruction exceptions.

`0b00` Legacy mode. Debug exceptions from Secure EL1 are enabled by the IMPLEMENTATION DEFINED authentication interface.

`0b10` Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.

`0b11` Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as `0b00`. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field has no effect on Breakpoint Instruction exceptions. These are always enabled.

This field is:

- Ignored if the PE is either:
  - In Non-secure state.
  - In Secure state and Secure EL1 is using AArch64.
- RES0 if the implementation does not support EL1 using AArch32.

If Secure EL1 is using AArch32 then:

- If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.
- Otherwise, debug exceptions from Secure EL0 are enabled only if the value of SDER32_EL3.SUIDEN is `0b1`.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b0`, then the Effective value of this field is `0b11`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSPB, bits [13:12]

When SPE is implemented:

Non-secure Profiling Buffer. This field controls the owning translation regime and accesses to Statistical Profiling and Profiling Buffer control registers.

`0b00` Profiling Buffer uses Secure Virtual Addresses. Statistical Profiling enabled in Secure state and disabled in Non-secure state. Accesses to Statistical Profiling and Profiling Buffer control registers at EL2 and EL1 in both security states generate Trap exceptions to EL3.

`0b01` Profiling Buffer uses Secure Virtual Addresses. Statistical Profiling enabled in Secure state and disabled in Non-secure state. Accesses to Statistical Profiling and Profiling Buffer control registers in Non-secure state generate Trap exceptions to EL3.

`0b10` Profiling Buffer uses Non-secure Virtual Addresses. Statistical Profiling enabled in Non-secure state and disabled in Secure state. Accesses to Statistical Profiling and Profiling Buffer control registers at EL2 and EL1 in both security states generate Trap exceptions to EL3.

`0b11` Profiling Buffer uses Non-secure Virtual Addresses. Statistical Profiling enabled in Non-secure state and disabled in Secure state. Accesses to Statistical Profiling and Profiling Buffer control registers in Secure state generate Trap exceptions to EL3.

The Statistical Profiling and Profiling Buffer control registers trapped by this control are: PMBLIMITR_EL1, PMBPTR_EL1, PMBSR_EL1, PMSCR_EL1, PMSCR_EL2, PMSEVFR_EL1, PMSFCR_EL1, PMSICR_EL1, PMSIDR_EL1, PMSIRR_EL1, and PMSLATFR_EL1.

If EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b1`, the Effective value of this field is `0b11`. If EL3 is not implemented and the Effective value of SCR_EL3.NS is `0b0`, the Effective value of this field is `0b01`.

Otherwise:

Reserved, RES0.

Bit [11]

Reserved, RES0.

TDOSA, bit [10]

When ARMv8.0-DoubleLock is implemented:

Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3.

Accesses to the registers are trapped as follows:

- Accesses from AArch64 state, OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1 and any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit, are trapped to EL3 and reported using EC syndrome value `0x18`.
- Accesses using MCR or MRC to DBGOSLAR, DBGOSLSR, DBGOSDLR, and DBGPRCR, are trapped to EL3 and reported using EC syndrome value `0x05`.
- Accesses to any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3, unless it is trapped by HDCR.TDOSA or MDCR_EL2.TDOSA.

Note

The powerdown debug registers are not accessible at EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3.

The following registers are affected by this trap:

- AArch64: OSLAR_EL1, OSLSR_EL1, and DBGPRCR_EL1.
- AArch32: DBGOSLAR, DBGOSLSR, and DBGPRCR.
- AArch64 and AArch32: Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.
- It is IMPLEMENTATION DEFINED whether accesses to OSDLR_EL1 and DBGOSDLR are trapped.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3, unless it is trapped by HDCR.TDOSA or MDCR_EL2.TDOSA.

Note

The powerdown debug registers are not accessible at EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDA, bit [9]

Trap Debug Access. Traps EL2, EL1, and EL0 System register accesses to those debug System registers that cannot be trapped using the MDCR_EL3.TDOSA field.

Accesses to the debug registers are trapped as follows:

- In AArch64 state, the following registers are trapped to EL3 and reported using EC syndrome value `0x18`:
  - DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, DBGWCR<n>_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, DBGAUTHSTATUS_EL1, DBGVCR32_EL2.
  - AArch64: MDCR_EL2, MDRAR_EL1, MDCCSR_EL0, MDCCINT_EL1, MDSCR_EL1, OSDTRRX_EL1, OSDTRTX_EL1, OSECCR_EL1.
- In AArch32 state, SDER is trapped to EL3 and reported using EC syndrome value `0x03`.
- In AArch32 state, accesses using MCR or MRC to the following registers are reported using EC syndrome value `0x05`, accesses using MCRR or MRRC are reported using EC syndrome value `0x0C`:
  - HDCR, DBGDRAR, DBGDSAR, DBGDIDR, DBGDCCINT, DBGWFAR, DBGVCR, DBGBVR<n>, DBGBCR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>.
  - DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, DBGOSECCR.
- In AArch32 state, STC accesses to DBGDTRRXint and LDC accesses to DBGDTRTXint are reported using EC syndrome value `0x06`.
- When not in Debug state, the following registers are also trapped to EL3:
  - AArch64 accesses to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0, reported using EC syndrome value `0x18`.
  - AArch32 accesses using MCR or MRC to DBGDTRRXint and DBGDTRTXint, reported using EC syndrome value `0x05`.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL0, EL1, and EL2 accesses to the debug registers, other than the registers that can be trapped by MDCR_EL3.TDOSA, are trapped to EL3, from both Security states and both Execution states, unless it is trapped by DBGDSCRext.UDCCdis, MDSCR_EL1.TDCC, HDCR.TDA or MDCR_EL2.TDA.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:7]

Reserved, RES0.

TPM, bit [6]

When PMUv3 is implemented:

Trap Performance Monitor register accesses. Accesses to all Performance Monitor registers from EL0, EL1 and EL2 to EL3, from both Security states and both Execution states are trapped as follows:

- In AArch64 state, accesses to the following registers are trapped to EL3 and are reported using EC syndrome value `0x18`:
  - PMCR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMOVSCLR_EL0, PMSWINC_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMXEVCNTR_EL0, PMUSERENR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0.
- In AArch32 state, accesses using MCR or MRC to the following registers are reported using EC syndrome value `0x03`, accesses using MCRR or MRRC are reported using EC syndrome value `0x04`:
  - PMCR, PMCNTENSET, PMCNTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.
- If ARMv8.4-PMU is implemented, in AArch64 state, PMMIR_EL1 and in AArch32 state, PMMIR.
- If ARMv8.1-PMU is implemented, in AArch32 state, PMCEID2 and PMCEID3.

`0b0` This control does not cause any instructions to be trapped.

`0b1` EL2, EL1, and EL0 System register accesses to all Performance Monitor registers are trapped to EL3, unless it is trapped by HDCR.TPM or MDCR_EL2.TPM.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D13.3.19 MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

Purpose

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. Armv8 deprecates any use of this register.

Configurations

AArch64 System register MDRAR_EL1[63:0] is architecturally mapped to AArch32 System register DBGDRAR[63:0].

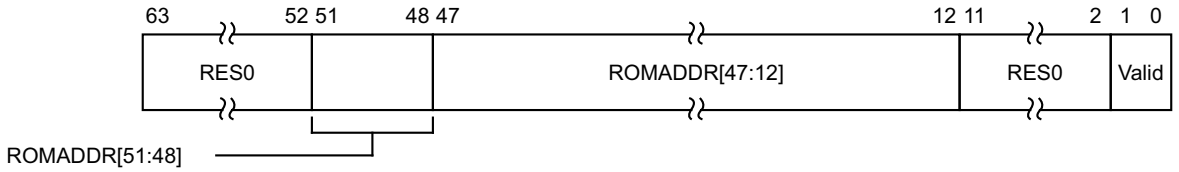
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDRAR_EL1 is a 64-bit register.

Field descriptions

The MDRAR_EL1 bit assignments are:



Bits [63:52]

Reserved, RES0.

ROMADDR[51:48], bits [51:48]

When ARMv8.2-LPA is implemented:

Extension to ROMADDR[47:12]. See ROMADDR[47:12] for more details.

Otherwise:

Reserved, RES0.

ROMADDR[47:12], bits [47:12]

Bits[47:12] of the ROM table physical address.

When ARMv8.2-LPA is implemented, ROMADDR[51:48] forms the upper part of the address value. Otherwise, ROMADDR[51:48] is RES0.

If the physical address size in bits (PAsize) is less than 52, then the register bits corresponding to ROMADDR [51:PAsize] are RES0.

Bits [11:0] of the ROM table physical address are zero.

Arm strongly recommends that bits ROMADDR[(PAsize-1):32] are zero in any system that supports AArch32 at the highest implemented Exception level.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Bits [11:2]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

`0b00` ROM Table address is not valid. Software must ignore ROMADDR.

`0b11` ROM Table address is valid.

Other values are reserved.

Accessing the MDRAR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, MDRAR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && MDCR_EL2.<TDE,TDRA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif HaveEL(EL3) && !ELUsingAArch32(EL3) && MDCR_EL3.TDA == '1' then
        AArch64.SystemAccessTrap(EL3, 0x18);
    else
        return MDRAR_EL1;
elsif PSTATE.EL == EL2 then
    if HaveEL(EL3) && !ELUsingAArch32(EL3) && MDCR_EL3.TDA == '1' then
        AArch64.SystemAccessTrap(EL3, 0x18);
    else
        return MDRAR_EL1;
elsif PSTATE.EL == EL3 then
    return MDRAR_EL1;
```

D13.3.20 MDSCR_EL1, Monitor Debug System Control Register

The MDSCR_EL1 characteristics are:

Purpose

Main control register for the debug implementation.

Configurations

AArch64 System register MDSCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGDSCRext[31:0].

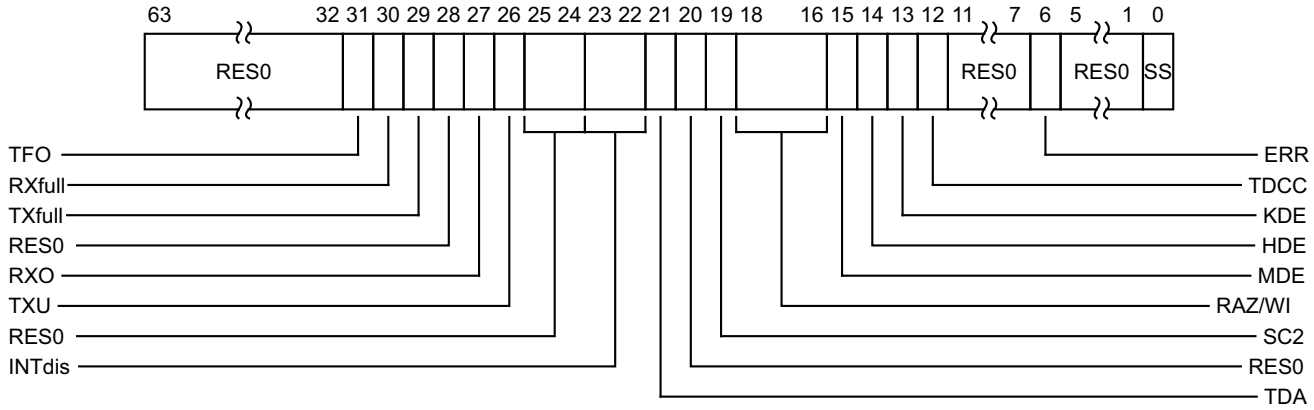
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDSCR_EL1 is a 64-bit register.

Field descriptions

The MDSCR_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

TFO, bit [31]

When ARMv8.4-Trace is implemented:

Trace Filter override. Used for save/restore of EDSCR.TFO.

When the OS Lock is unlocked, OSLSR_EL1.OSLK == 0, this bit ignores writes, and software must treat it as UNK/SBZP.

When the OS Lock is locked, OSLSR_EL1.OSLK == 1, this bit is RW, and holds the value of EDSCR.TFO.

Reads and writes of this bit are indirect accesses to EDSCR.TFO.

Otherwise:

Reserved, RES0.

RXfull, bit [30]

Used for save/restore of EDSCR.RXfull.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.RXfull.

Reads and writes of this bit are indirect accesses to EDSCR.RXfull.

The architected behavior of this field determines the value it returns after a reset.

TXfull, bit [29]

Used for save/restore of EDSCR.TXfull.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.TXfull.

Reads and writes of this bit are indirect accesses to EDSCR.TXfull.

The architected behavior of this field determines the value it returns after a reset.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of EDSCR.RXO.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.RXO.

Reads and writes of this bit are indirect accesses to EDSCR.RXO.

The architected behavior of this field determines the value it returns after a reset.

TXU, bit [26]

Used for save/restore of EDSCR.TXU.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.TXU.

Reads and writes of this bit are indirect accesses to EDSCR.TXU.

The architected behavior of this field determines the value it returns after a reset.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of EDSCR.INTdis.

When OSLSR_EL1.OSLK == 0, this field is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this field is RW and holds the value of EDSCR.INTdis.

Reads and writes of this field are indirect accesses to EDSCR.INTdis.

The architected behavior of this field determines the value it returns after a reset.

TDA, bit [21]

Used for save/restore of EDSCR.TDA.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.TDA.

Reads and writes of this bit are indirect accesses to EDSCR.TDA.

The architected behavior of this field determines the value it returns after a reset.

Bit [20]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SC2, bit [19]

When ARMv8.0-PCSample is implemented, ARMv8.1-VHE is implemented and ARMv8.2-PCSample is not implemented:

Used for save/restore of EDSCR.SC2.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.SC2.

Reads and writes of this bit are indirect accesses to EDSCR.SC2.

Otherwise:

Reserved, RES0.

Bits [18:16]

Reserved, RAZ/WI.

Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

MDE, bit [15]

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

`0b0` Breakpoint, Watchpoint, and Vector Catch exceptions disabled.

`0b1` Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.HDE.

Reads and writes of this bit are indirect accesses to EDSCR.HDE.

The architected behavior of this field determines the value it returns after a reset.

KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable debug exceptions within EL_D. Permitted values are:

`0b0` Debug exceptions, other than Breakpoint Instruction exceptions, disabled within EL_D.

`0b1` All debug exceptions enabled within EL_D.

RES0 if EL_D is using AArch32.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDCC, bit [12]

Traps EL0 accesses to the Debug Communication Channel (DCC) registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states, as follows:

- In AArch64 state, MRS or MSR accesses to the following DCC registers are trapped, reported using EC syndrome value `0x18`:
  - MDCCSR_EL0.
  - If not in Debug state, DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped, reported using EC syndrome value `0x05`.
  - DBGDSCRint, DBGDIDR, DBGDSAR, DBGDRAR, .
  - If not in Debug state, DBGDTRRXint, and DBGDTRTXint.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch32 state, LDC access to DBGDTRRXint and STC access to DBGDTRTXint are trapped, reported using EC syndrome value 0x06.
- In AArch32 state, MRRC accesses to DBGDSAR and DBGDRAR are trapped, reported using EC syndrome value 0x0C.

0b0 This control does not cause any instructions to be trapped.

0b1 EL0 using AArch64: EL0 accesses to the AArch64 DCC registers are trapped.
EL0 using AArch32: EL0 accesses to the AArch32 DCC registers are trapped.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.

When OSLSR_EL1.OSLK == 0, this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit is RW and holds the value of EDSCR.ERR.

Reads and writes of this bit are indirect accesses to EDSCR.ERR.

The architected behavior of this field determines the value it returns after a reset.

Bits [5:1]

Reserved, RES0.

SS, bit [0]

Software step control bit. If EL_D is using AArch64, enable Software step. Permitted values are:

0b0 Software step disabled

0b1 Software step enabled.

RES0 if EL_D is using AArch32.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the MDSCR_EL1

Individual fields within this register might have restricted accessibility when OSLSR_EL1.OSLK == 0 (the OS lock is unlocked). See the field descriptions for more detail.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, MDSCR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b010

D13.3.21 OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

Purpose

Used to control the OS Double Lock.

Configurations

AArch64 System register OSDLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSDLR[31:0].

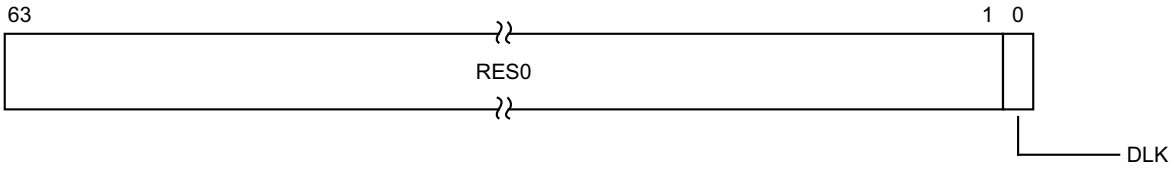
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

OSDLR_EL1 is a 64-bit register.

Field descriptions

The OSDLR_EL1 bit assignments are:



Bits [63:1]

Reserved, RES0.

DLK, bit [0]

When ARMv8.0-DoubleLock is implemented:

OS Double Lock control bit.

`0b0` OS Double Lock unlocked.

`0b1` OS Double Lock locked, if DBGPRCR_EL1.CORENPDRQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

On a Warm reset, this field resets to `0`.

Otherwise:

Reserved, RAZ/WI.

D13.3.22 OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

Purpose

Used for save/restore of DBGDTRRX_EL0. It is a component of the Debug Communications Channel.

Configurations

AArch64 System register OSDTRRX_EL1[31:0] is architecturally mapped to AArch32 System register DBGDTRRXext[31:0].

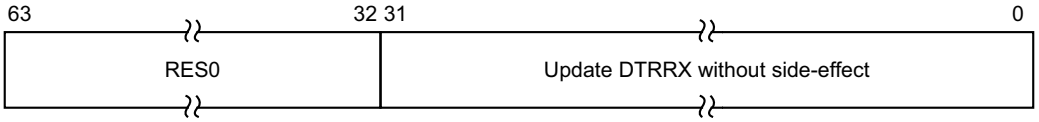
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

OSDTRRX_EL1 is a 64-bit register.

Field descriptions

The OSDTRRX_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

Bits [31:0]

Update DTRRX without side-effect.

Writes to this register update the value in DTRRX and do not change RXfull.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

Accessing the OSDTRRX_EL1

Arm deprecates reads and writes of OSDTRRX_EL1 when the OS Lock is unlocked.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.24 OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

Configurations

AArch64 System register OSECCR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSECCR[31:0].

AArch64 System register OSECCR_EL1[31:0] is architecturally mapped to External register EDECCR[31:0].

If OSLSR_EL1.OSLK == 0, then OSECCR_EL1 returns an UNKNOWN value on reads and ignores writes.

RW fields in this register reset to architecturally UNKNOWN values.

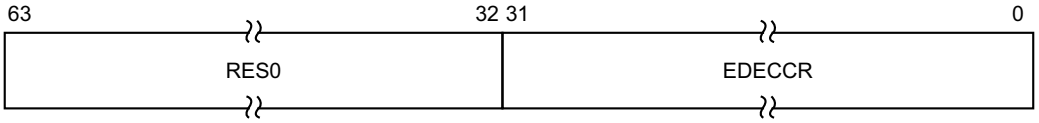
Attributes

OSECCR_EL1 is a 64-bit register.

Field descriptions

The OSECCR_EL1 bit assignments are:

When DBGOSLSR.OSLK == 1:



Bits [63:32]

Reserved, RES0.

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Reads or writes to this field are indirect accesses to EDECCR.

Accessing the OSECCR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, OSECCR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0110	0b010

D13.3.25 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS Lock.

Configurations

AArch64 System register OSLAR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSLAR[31:0].

AArch64 System register OSLAR_EL1[31:0] is architecturally mapped to External register OSLAR_EL1[31:0].

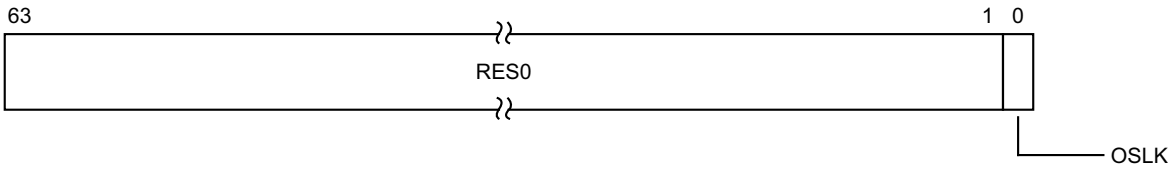
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

OSLAR_EL1 is a 64-bit register.

Field descriptions

The OSLAR_EL1 bit assignments are:



Bits [63:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS Lock.

Use OSLSR_EL1.OSLK to check the current status of the lock.

Accessing the OSLAR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MSR OSLAR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0000	0b100

```
if PSTATE.EL == EL0 then

D13.3.26 OSLSR_EL1, OS Lock Status Register

The OSLSR_EL1 characteristics are:

Purpose

Provides the status of the OS Lock.

Configurations

AArch64 System register OSLSR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSLSR[31:0].

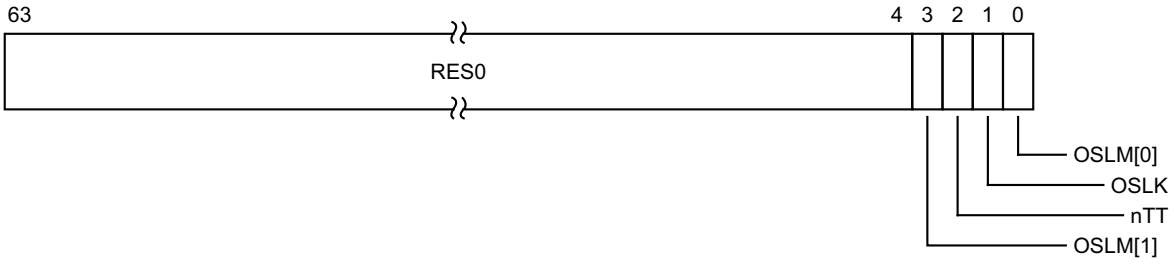
This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

OSLSR_EL1 is a 64-bit register.

Field descriptions

The OSLSR_EL1 bit assignments are:



Bits [63:4]

Reserved, RES0.

OSLM[1], bit [3]

This field is bit[1] of OSLM[1:0].

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented.

`0b00` OS Lock not implemented.

`0b10` OS Lock implemented.

All other values are reserved. In an Armv8 implementation the value `0b00` is not permitted.

The OSLM field is split as follows:

- OSLM[1] is OSLSR_EL1[3].
- OSLM[0] is OSLSR_EL1[0].

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status.

`0b0` OS Lock unlocked.

`0b1` OS Lock locked.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On a Cold reset, this field resets to 1.

OSLM[0], bit [0]

This field is bit[0] of OSLM[1:0].

See OSLM[1] for the field description.

Accessing the OSLSR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, OSLSR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0001	0b100

D13.3.27 SDER32_EL2, AArch32 Secure Debug Enable Register

The SDER32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register SDER from Secure EL2 and EL3 only.

Configurations

This register is present only when ARMv8.4-SecEL2 is implemented, EL1 supports AArch32 and (HaveEL(EL3) or the implemented Security state is Secure state). Otherwise, direct accesses to SDER32_EL2 are UNDEFINED.

This register is ignored by the PE when one or more of the following are true:

- The PE is in Non-secure state.
- EL1 is using AArch64.

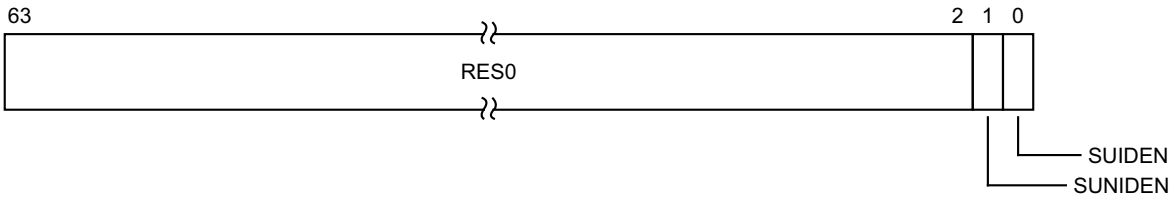
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SDER32_EL2 is a 64-bit register.

Field descriptions

The SDER32_EL2 bit assignments are:



Bits [63:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable.

0b0 This bit does not affect Performance Monitors event counting at Secure EL0.

0b1 If EL1 is using AArch32, Performance Monitors event counting is allowed in Secure EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SUIDEN, bit [0]

Secure User Invasive Debug Enable.

0b0 This bit does not affect the generation of debug exceptions at Secure EL0.

0b1 If EL1 is using AArch32, debug exceptions from Secure EL0 are enabled.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the SDER32_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.28 SDER32_EL3, AArch32 Secure Debug Enable Register

The SDER32_EL3 characteristics are:

Purpose

Allows access to the AArch32 register SDER from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configurations

AArch64 System register SDER32_EL3[31:0] is architecturally mapped to AArch32 System register SDER[31:0].

This register is present only when EL1 supports AArch32. Otherwise, direct accesses to SDER32_EL3 are UNDEFINED.

This register is ignored by the PE when one or more of the following are true:

- The PE is in Non-secure state.
- EL1 is using AArch64.

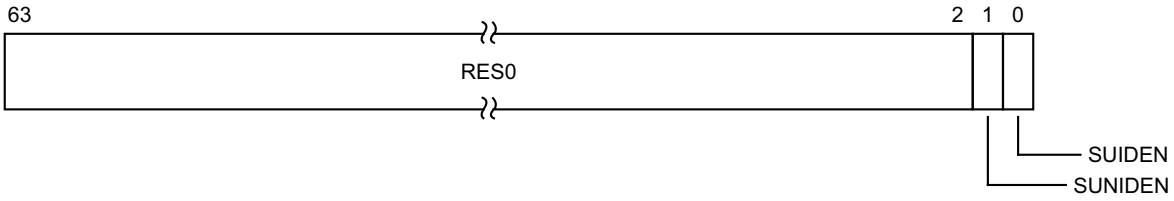
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SDER32_EL3 is a 64-bit register.

Field descriptions

The SDER32_EL3 bit assignments are:



Bits [63:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable.

0b0 This bit does not affect Performance Monitors event counting at Secure EL0.

0b1 If EL1 is using AArch32, Performance Monitors event counting is allowed in Secure EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SUIDEN, bit [0]

Secure User Invasive Debug Enable.

0b0 This bit does not affect the generation of debug exceptions at Secure EL0.

0b1 If EL1 is using AArch32, debug exceptions from Secure EL0 are enabled.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.3.29 TRFCR_EL1, Trace Filter Control Register (EL1)

The TRFCR_EL1 characteristics are:

Purpose

Provides EL1 controls for Trace.

Configurations

AArch64 System register TRFCR_EL1[31:0] is architecturally mapped to AArch32 System register TRFCR[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to TRFCR_EL1 are UNDEFINED.

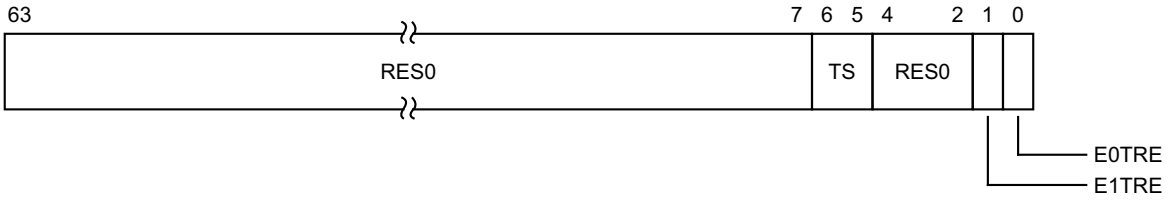
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TRFCR_EL1 is a 64-bit register.

Field descriptions

The TRFCR_EL1 bit assignments are:



Bits [63:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control

`0b01` Virtual timestamp. The traced timestamp is the physical counter value, minus the value of CNTVOFF_EL2.

`0b11` Physical timestamp. The traced timestamp is the physical counter value.

All other values are reserved

This field is ignored if any of the following are true:

- SelfHostedTraceEnabled() == FALSE.
- EL2 is implemented and TRFCR_EL2.TS != `0b00`.

Bits [4:2]

Reserved, RES0.

E1TRE, bit [1]

EL1 Trace Enable.

`0b0` Trace is prohibited at EL1.

`0b1` Trace is allowed at EL1.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E0TRE, bit [0]

EL0 Trace Enable.

`0b0` Trace is prohibited at EL0.

`0b1` Trace is allowed at EL0.

This field is ignored if any of the following are true:

- SelfHostedTraceEnabled() == FALSE.
- EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE == 1.

On a Warm reset, this field resets to `0`.

Accessing the TRFCR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.3.30 TRFCR_EL2, Trace Filter Control Register (EL2)

The TRFCR_EL2 characteristics are:

Purpose

Provides EL2 controls for Trace.

Configurations

AArch64 System register TRFCR_EL2[31:0] is architecturally mapped to AArch32 System register HTRFCR[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to TRFCR_EL2 are UNDEFINED.

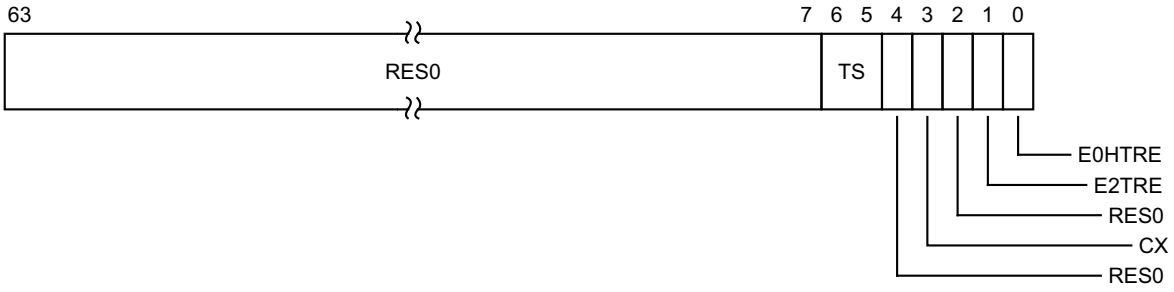
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TRFCR_EL2 is a 64-bit register.

Field descriptions

The TRFCR_EL2 bit assignments are:



Bits [63:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

`0b00` Timestamp controlled by TRFCR_EL1.TS or TRFCR.TS.

`0b01` Virtual timestamp. The traced timestamp is the physical counter value, minus the value of CNTVOFF_EL2.

`0b11` Physical timestamp. The traced timestamp is the physical counter value.

This field is ignored if SelfHostedTraceEnabled() == FALSE.

On a Warm reset, this field resets to `0`.

Bit [4]

Reserved, RES0.

CX, bit [3]

CONTEXTIDR_EL2 and VMID trace enable.

`0b0` CONTEXTIDR_EL2 and VMID trace prohibited.

`0b1` CONTEXTIDR_EL2 and VMID trace allowed.

This field is ignored if SelfHostedTraceEnabled() == FALSE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Warm reset, this field resets to 0.

Bit [2]

Reserved, RES0.

E2TRE, bit [1]

EL2 Trace Enable.

0b0 Trace is prohibited at EL2.

0b1 Trace is allowed at EL2.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, this field resets to 0.

E0HTRE, bit [0]

EL0 Trace Enable.

0b0 Trace is prohibited at EL0 when HCR_EL2.TGE == 1.

0b1 Trace is allowed at EL0 when HCR_EL2.TGE == 1.

This field is ignored if any of the following are true:

- HCR_EL2.TGE == 0.
- SelfHostedTraceEnabled() == FALSE.
- EL2 is disabled in the current security state.

On a Warm reset, this field resets to 0.

D13.4 Performance Monitors registers

This section lists the Performance Monitoring registers in AArch64.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D13.4.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

Configurations

AArch64 System register PMCCFILTR_EL0[31:0] is architecturally mapped to AArch32 System register PMCCFILTR[31:0].

AArch64 System register PMCCFILTR_EL0[31:0] is architecturally mapped to External register PMCCFILTR_EL0[31:0].

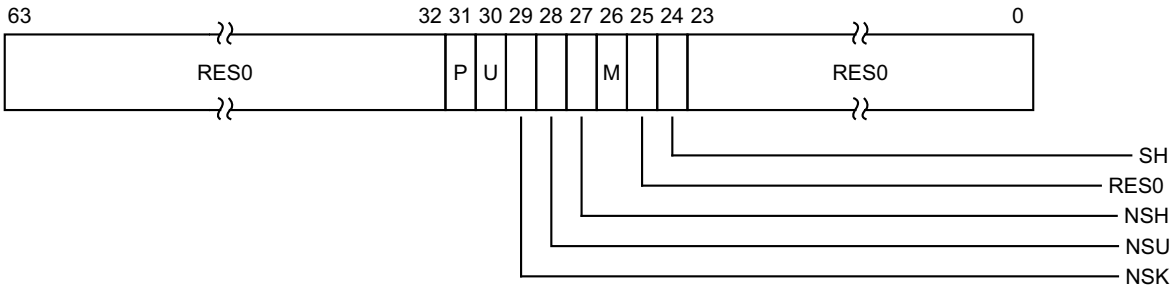
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCFILTR_EL0 is a 64-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMCCFILTR_EL0.NSK bit. The possible values of this bit are:

`0b0` Count cycles in EL1.

`0b1` Do not count cycles in EL1.

This field resets to an architecturally UNKNOWN value.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMCCFILTR_EL0.NSU bit. The possible values of this bit are:

`0b0` Count cycles in EL0.

`0b1` Do not count cycles in EL0.

This field resets to an architecturally UNKNOWN value.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

This field resets to an architecturally UNKNOWN value.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMCCFILTR_EL0.U bit, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

This field resets to an architecturally UNKNOWN value.

NSH, bit [27]

EL2 (Hypervisor) filtering bit. Controls counting in EL2. If EL2 is not implemented, this bit is RES0. If Secure EL2 is implemented, counting in Secure EL2 is further controlled by the PMCCFILTR_EL0.SH bit.

`0b0` Do not count cycles in EL2.

`0b1` Count cycles in EL2.

This field resets to an architecturally UNKNOWN value.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

Note

This field is not visible in the AArch32 PMCCFILTR System register.

This field resets to an architecturally UNKNOWN value.

Bit [25]

Reserved, RES0.

SH, bit [24]

When ARMv8.4-SecEL2 is implemented:

Secure EL2 filtering.

If the value of this bit is not equal to the value of the PMCCFILTR_EL0.NSH bit, cycles in Secure EL2 are counted.

Otherwise, cycles in Secure EL2 are not counted.

If Secure EL2 is not implemented or is disabled, this field is RES0.

Note

This field is not visible in the AArch32 PMCCFILTR System register.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [23:0]

Reserved, RES0.

D13.4.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D7-2671 for more information.

PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

Configurations

AArch64 System register PMCCNTR_EL0[63:0] is architecturally mapped to AArch32 System register PMCCNTR[63:0].

AArch64 System register PMCCNTR_EL0[63:0] is architecturally mapped to External register PMCCNTR_EL0[63:0].

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

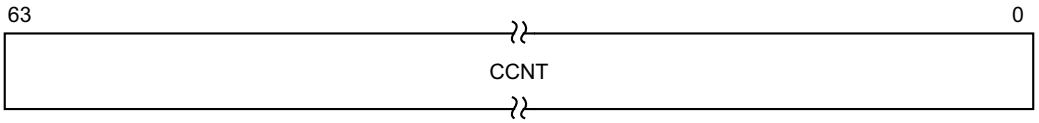
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

The PMCCNTR_EL0 bit assignments are:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

This field resets to an architecturally UNKNOWN value.

Accessing the PMCCNTR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMCCNTR_EL0

op0	op1	CRn	CRm	op2

D13.4.3 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the ranges `0x0000` to `0x001F` and `0x4000` to `0x401F`.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEID<n>_EL0 registers see *The PMU event number space and common events* on page D7-2693.

Configurations

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to AArch32 System register PMCEID0[31:0].

AArch64 System register PMCEID0_EL0[63:32] is architecturally mapped to AArch32 System register PMCEID2[31:0].

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to External register PMCEID0[31:0].

AArch64 System register PMCEID0_EL0[63:32] is architecturally mapped to External register PMCEID2[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

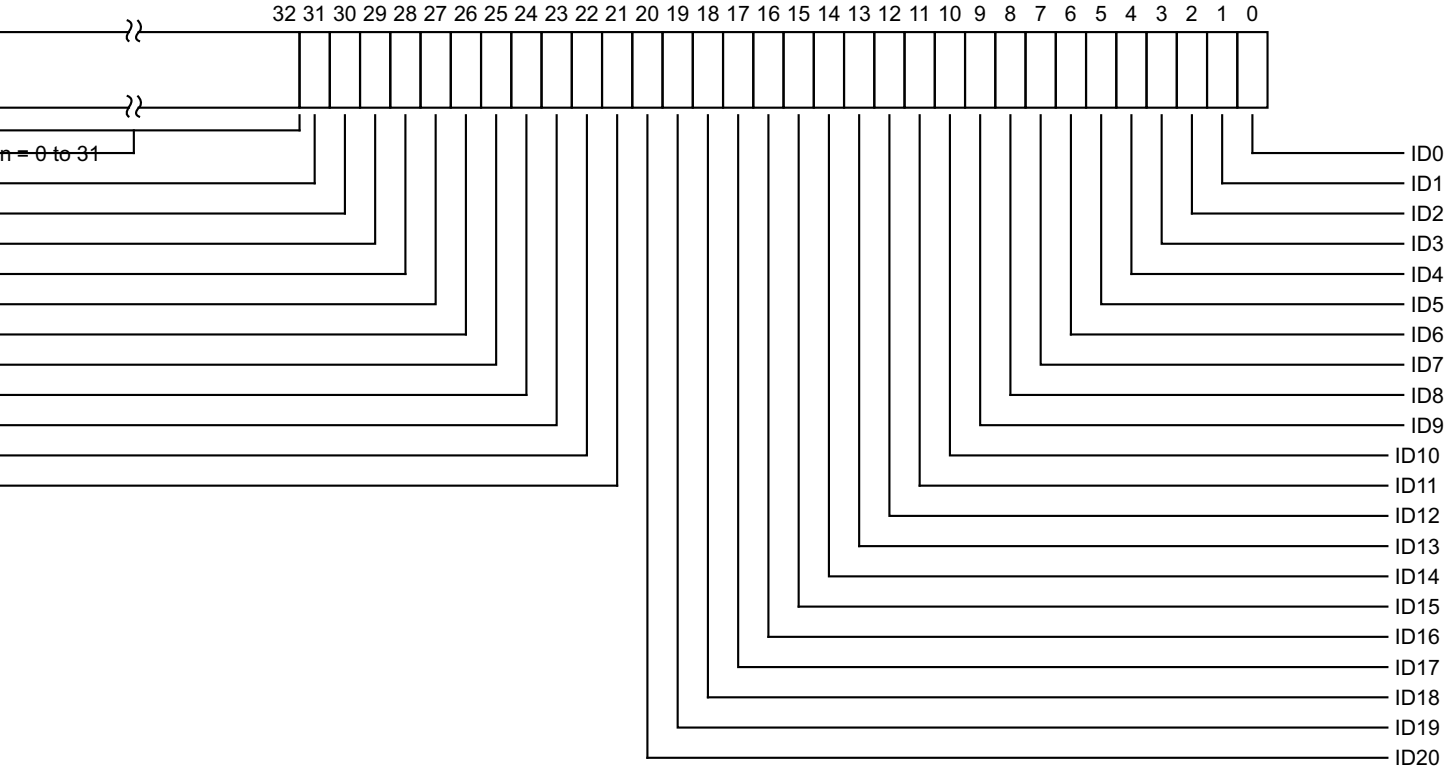
Attributes

PMCEID0_EL0 is a 64-bit register.

Field descriptions

The PMCEID0_EL0 bit assignments are:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



IDhi<n>, bit [n+32], for n = 0 to 31

When ARMv8.1-PMU is implemented:

IDhi[n] corresponds to common event (0x4000 + n).

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Otherwise:

Reserved, RES0.

ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event n.

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Accessing the PMCEID0_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMCEID0_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b110

```

D13.4.4 PMCEID1_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1_EL0 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the ranges `0x0020` to `0x003F` and `0x4020` to `0x403F`.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEID<n>_EL0 registers see *The PMU event number space and common events* on page D7-2693.

Configurations

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to AArch32 System register PMCEID1[31:0].

AArch64 System register PMCEID1_EL0[63:32] is architecturally mapped to AArch32 System register PMCEID3[31:0].

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to External register PMCEID1[31:0].

AArch64 System register PMCEID1_EL0[63:32] is architecturally mapped to External register PMCEID3[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

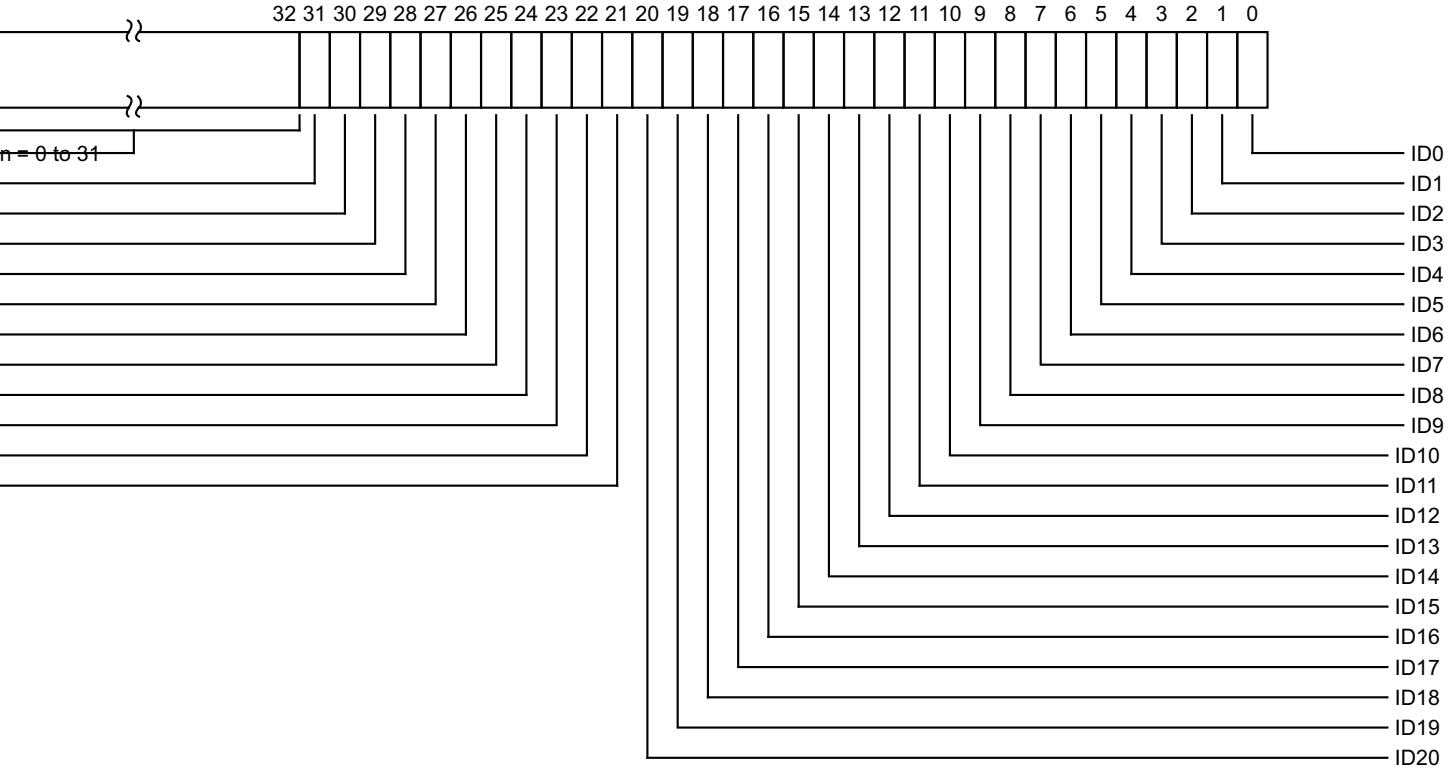
Attributes

PMCEID1_EL0 is a 64-bit register.

Field descriptions

The PMCEID1_EL0 bit assignments are:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



IDhi<n>, bit [n+32], for n = 0 to 31

When ARMv8.1-PMU is implemented:

IDhi[n] corresponds to common event (0x4020 + n).

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Otherwise:

Reserved, RES0.

ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event (0x0020 + n).

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

D13.4.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

Configurations

AArch64 System register PMCNTENCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENCLR[31:0].

AArch64 System register PMCNTENCLR_EL0[31:0] is architecturally mapped to External register PMCNTENCLR_EL0[31:0].

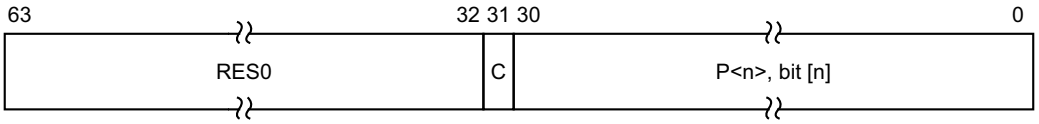
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENCLR_EL0 is a 64-bit register.

Field descriptions

The PMCNTENCLR_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:

0b0 When read, means the cycle counter is disabled. When written, has no effect.

0b1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter disable bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

0b0 When read, means that PMEVCNTR<n>_EL0 is disabled. When written, has no effect.

0b1 When read, means that PMEVCNTR<n>_EL0 is enabled. When written, disables PMEVCNTR<n>_EL0.

This field resets to an architecturally UNKNOWN value.

D13.4.6 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

Configurations

AArch64 System register PMCNTENSET_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENSET[31:0].

AArch64 System register PMCNTENSET_EL0[31:0] is architecturally mapped to External register PMCNTENSET_EL0[31:0].

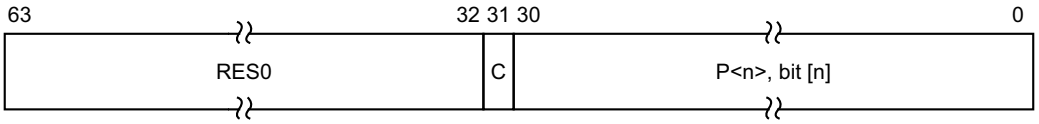
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENSET_EL0 is a 64-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

`0b0` When read, means the cycle counter is disabled. When written, has no effect.

`0b1` When read, means the cycle counter is enabled. When written, enables the cycle counter.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter enable bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

`0b0` When read, means that PMEVCNTR<n>_EL0 is disabled. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n>_EL0 event counter is enabled. When written, enables PMEVCNTR<n>_EL0.

This field resets to an architecturally UNKNOWN value.

Accessing the PMCNTENSET_EL0

D13.4.7 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Configurations

AArch64 System register PMCR_EL0[31:0] is architecturally mapped to AArch32 System register PMCR[31:0].

AArch64 System register PMCR_EL0[7:0] is architecturally mapped to External register PMCR_EL0[7:0].

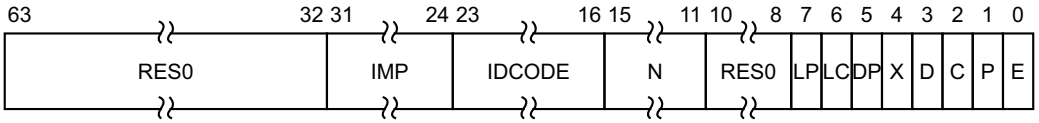
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCR_EL0 is a 64-bit register.

Field descriptions

The PMCR_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

If this field is zero, then PMCR_EL0.IDCODE is RES0 and software must use the MIDR_EL1 to identify the PE.

Otherwise, this field and PMCR_EL0.IDCODE identifies the PMU implementation to software. The implementer codes are allocated by Arm. A non-zero value has the same interpretation as MIDR_EL1.Implementer.

IDCODE, bits [23:16]

When PMCR_EL0.IMP != 0x00:

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that are specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

Otherwise:

Reserved, RES0.

N, bits [15:11]

An RO field that indicates the number of event counters implemented. This value is in the range of `0b00000`-`0b111111`. If the value is `0b00000` then only PMCCNTR_EL0 is implemented. If the value is `0b111111` PMCCNTR_EL0 and 31 event counters are implemented.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When EL2 is implemented and enabled for the current Security state, reads of this field from EL1 and EL0 return the value of MDCR_EL2.HPMN.

Access to this field is RO.

Bits [10:8]

Reserved, RES0.

LP, bit [7]

When ARMv8.5-PMU is implemented:

Long event counter enable. Determines when unsigned overflow is recorded by a counter overflow bit.

`0b0` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>_EL0[31:0].

`0b1` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>_EL0[63:0].

If EL2 is implemented and MDCR_EL2.HPMN or HDCR.HPMN is less than PMCR_EL0.N, this bit does not affect the operation of event counters in the range [HDCR.HPMN..(PMCR_EL0.N-1)] or [MDCR_EL2.HPMN..(PMCR_EL0.N-1)].

Note

The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines when unsigned overflow is recorded by the cycle counter overflow bit.

`0b0` Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[31:0].

`0b1` Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[63:0].

Arm deprecates use of PMCR_EL0.LC = 0.

In an AArch64 only implementation, this field is RES1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

`0b0` Cycle counting by PMCCNTR_EL0 is not affected by this bit.

`0b1` When event counting for counters in the range [0..(MDCR_EL2.HPMN-1)] is prohibited, cycle counting by PMCCNTR_EL0 is disabled.

For more information about the interaction between the Performance Monitors and EL3, see *Effect of EL3 and EL2* on page D7-2679.

When EL3 is not implemented, this field is RES0:

- When ARMv8.1-PMU is not implemented.
- When ARMv8.1-PMU is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0b0 Do not export events.

0b1 Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL PE trace unit. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D, bit [3]

Clock divider. The possible values of this bit are:

0b0 When enabled, PMCCNTR_EL0 counts every clock cycle.

0b1 When enabled, PMCCNTR_EL0 counts once every 64 clock cycles.

In an AArch64 only implementation this field is RES0, otherwise it is an RW field. If PMCR_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

Arm deprecates use of PMCR_EL0.D = 1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

0b0 No action.

0b1 Reset PMCCNTR_EL0 to zero.

This bit is always RAZ.

Note

Resetting PMCCNTR_EL0 does not change the cycle counter overflow bit.

The value of PMCR_EL0.LC is ignored, and bits [63:0] of all affected event counters are reset.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

0b0 No action.

0b1 Reset all event counters accessible in the current Exception level, not including PMCCNTR_EL0, to zero.

This bit is always RAZ.

In EL0 and EL1:

- If EL2 is implemented and enabled in the current Security state, and MDCR_EL2.HPMN is less than PMCR_EL0.N, a write of 1 to this bit does not reset event counters in the range [MDCR_EL2.HPMN..(PMCR_EL0.N-1)].
- If EL2 is not implemented, EL2 is disabled in the current Security state, or MDCR_EL2.HPMN equals PMCR_EL0.N, a write of 1 to this bit resets all the event counters.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Note

Resetting the event counters does not change the event counter overflow bits.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If ARMv8.5-PMU is implemented, the values of MDCR_EL2.HLP and PMCR_EL0.LP are ignored, and bits [63:0] of all affected event counters are reset.

E, bit [0]

Enable.

`0b0` All event counters in the range [0..(PMN-1)] and PMCCNTR_EL0, are disabled.

`0b1` All event counters in the range [0..(PMN-1)] and PMCCNTR_EL0, are enabled by PMCNTENSET_EL0.

This bit is RW.

If EL2 is implemented then:

- If EL2 is using AArch32, PMN is HDCR.HPMN.
- If EL2 is using AArch64, PMN is MDCR_EL2.HPMN.
- If PMN is less than PMCR_EL0.N, this bit does not affect the operation of event counters in the range [PMN..(PMCR_EL0.N-1)].

If EL2 is not implemented, PMN is PMCR_EL0.N.

Note

The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit applies if EL2 is implemented including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

On a Warm reset, this field resets to `0`.

D13.4.8 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configurations

AArch64 System register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVCNTR<n>[31:0].

AArch64 System register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to External register PMEVCNTR<n>_EL0[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

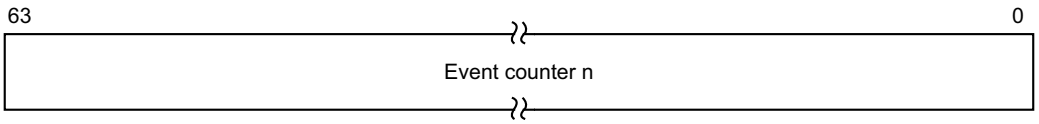
Attributes

PMEVCNTR<n>_EL0 is a 64-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:

When ARMv8.5-PMU is implemented:

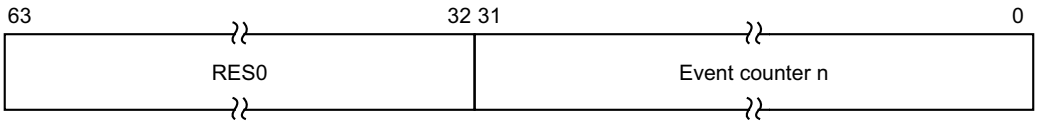


Bits [63:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

This field resets to an architecturally UNKNOWN value.

Otherwise:



Bits [63:32]

Reserved, RES0.

Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

This field resets to an architecturally UNKNOWN value.

Accessing the PMEVCNTR<n>_EL0

PMEVCNTR<n>_EL0 can also be accessed by using PMXEVCNTR_EL0 with PMSELR_EL0.SEL set to the value of <n>.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.{ER,EN}.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters. See MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMEVCNTR<n>_EL0

D13.4.9 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configurations

AArch64 System register PMEVTYPER<n>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVTYPER<n>[31:0].

AArch64 System register PMEVTYPER<n>_EL0[31:0] is architecturally mapped to External register PMEVTYPER<n>_EL0[31:0].

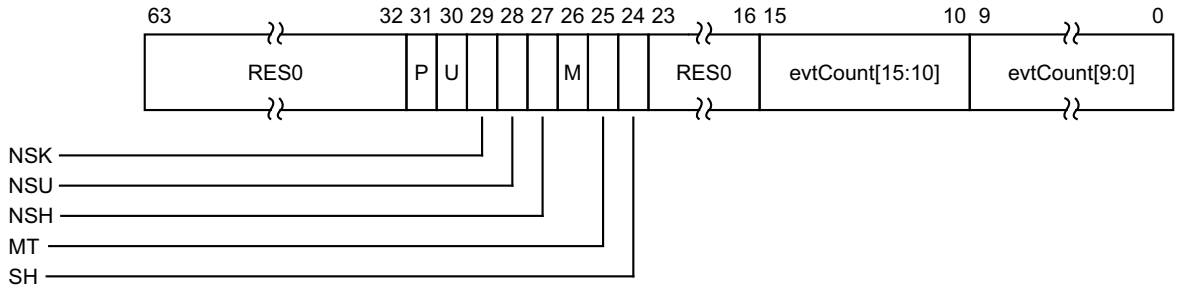
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVTYPER<n>_EL0 is a 64-bit register.

Field descriptions

The PMEVTYPER<n>_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMEVTYPER<n>_EL0.NSK bit. The possible values of this bit are:

`0b0` Count events in EL1.

`0b1` Do not count events in EL1.

This field resets to an architecturally UNKNOWN value.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMEVTYPER<n>_EL0.NSU bit. The possible values of this bit are:

`0b0` Count events in EL0.

`0b1` Do not count events in EL0.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.P bit, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

This field resets to an architecturally UNKNOWN value.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.U bit, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

This field resets to an architecturally UNKNOWN value.

NSH, bit [27]

EL2 (Hypervisor) filtering bit. Controls counting in EL2. If EL2 is not implemented, this bit is RES0. If Secure EL2 is implemented, counting in Secure EL2 is further controlled by the PMEVTYPER<n>_EL0.SH bit.

`0b0` Do not count events in EL2.

`0b1` Count events in EL2.

This field resets to an architecturally UNKNOWN value.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.P bit, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to `0b0`.

Note

This field is not visible in the AArch32 PMEVTYPER<n> System register.

This field resets to an architecturally UNKNOWN value.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

`0b0` Count events only on controlling PE.

`0b1` Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

Note

- When the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach, an implementation is described as multi-threaded. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, when read at the highest implemented Exception level, the value of the MPIDR_EL1.MT bit is `0b1`.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SH, bit [24]

When ARMv8.4-SecEL2 is implemented:

Secure EL2 filtering.

If the value of this bit is not equal to the value of the PMEVTYPER<n>_EL0.NSH bit, events in Secure EL2 are counted.

Otherwise, events in Secure EL2 are not counted.

If Secure EL2 is not implemented or is disabled, this field is RES0.

Note

This field is not visible in the AArch32 PMEVTYPER<n> System register.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [23:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

When ARMv8.1-PMU is implemented:

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>_EL0.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the value written:

- For the range `0x000` to `0x03F`, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- If 16-bit evtCount is implemented, for the range `0x4000` to `0x403F`, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

Arm recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

This field resets to an architecturally UNKNOWN value.

Accessing the PMEVTYPER<n>_EL0

PMEVTYPER<n>_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEL set to n.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.EN.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters. See MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.4.10 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

Configurations

AArch64 System register PMINTENCLR_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENCLR[31:0].

AArch64 System register PMINTENCLR_EL1[31:0] is architecturally mapped to External register PMINTENCLR_EL1[31:0].

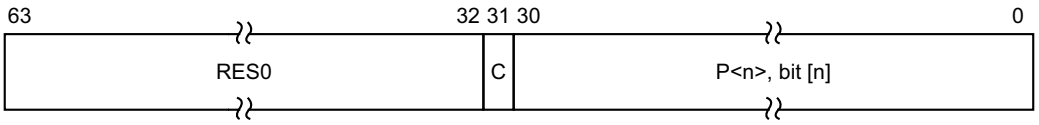
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENCLR_EL1 is a 64-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:

`0b0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`0b1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

`0b0` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is disabled. When written, has no effect.

`0b1` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR<n>_EL0 interrupt request.

This field resets to an architecturally UNKNOWN value.

D13.4.11 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

Configurations

AArch64 System register PMINTENSET_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENSET[31:0].

AArch64 System register PMINTENSET_EL1[31:0] is architecturally mapped to External register PMINTENSET_EL1[31:0].

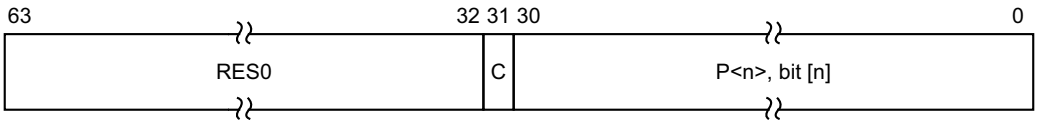
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENSET_EL1 is a 64-bit register.

Field descriptions

The PMINTENSET_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:

`0b0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`0b1` When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

`0b0` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is disabled. When written, has no effect.

`0b1` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is enabled. When written, enables the PMEVCNTR<n>_EL0 interrupt request.

This field resets to an architecturally UNKNOWN value.

D13.4.12 PMMIR_EL1, Performance Monitors Machine Identification Register

The PMMIR_EL1 characteristics are:

Purpose

Describes Performance Monitors parameters specific to the implementation to software.

Configurations

This register is present only when ARMv8.4-PMU is implemented. Otherwise, direct accesses to PMMIR_EL1 are UNDEFINED.

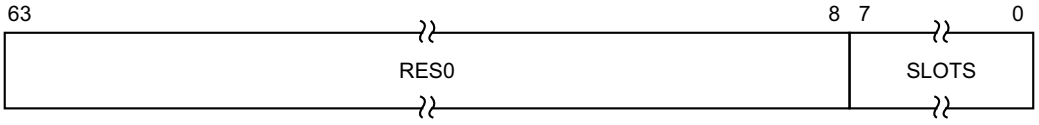
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMMIR_EL1 is a 64-bit register.

Field descriptions

The PMMIR_EL1 bit assignments are:



Bits [63:8]

Reserved, RES0.

SLOTS, bits [7:0]

Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL_SLOT event is not implemented, this field might read as zero.

Accessing the PMMIR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMMIR_EL1

op0	op1	CRn	CRm	op2

D13.4.13 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register

The PMOVSCLR_EL0 characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>. Writing to this register clears these bits.

Configurations

AArch64 System register PMOVSCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMOVSR[31:0].

AArch64 System register PMOVSCLR_EL0[31:0] is architecturally mapped to External register PMOVSCLR_EL0[31:0].

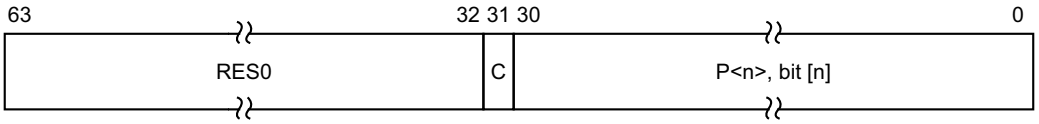
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSCLR_EL0 is a 64-bit register.

Field descriptions

The PMOVSCLR_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

C, bit [31]

Cycle counter overflow clear bit.

`0b0` When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means the cycle counter has overflowed since this bit was last cleared. When written, clears the cycle counter overflow bit to 0.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow clear bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

`0b0` When read, means that PMEVCNTR<n>_EL0 has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n>_EL0 has overflowed since this bit was last cleared. When written, clears the PMEVCNTR<n>_EL0 overflow bit to 0.

If ARMv8.5-PMU is implemented, MDCR_EL2.HLP and PMCR_EL0.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR<n>_EL0[31:0] or unsigned overflow of PMEVCNTR<n>_EL0[63:0].

This field resets to an architecturally UNKNOWN value.

D13.4.14 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>.

Configurations

AArch64 System register PMOVSSET_EL0[31:0] is architecturally mapped to AArch32 System register PMOVSSET[31:0].

AArch64 System register PMOVSSET_EL0[31:0] is architecturally mapped to External register PMOVSSET_EL0[31:0].

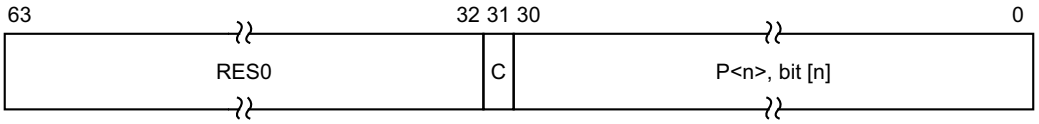
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSSET_EL0 is a 64-bit register.

Field descriptions

The PMOVSSET_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

C, bit [31]

Cycle counter overflow set bit.

`0b0` When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means the cycle counter has overflowed since this bit was last cleared. When written, sets the cycle counter overflow bit to 1.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow set bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

`0b0` When read, means that PMEVCNTR<n>_EL0 has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n>_EL0 has overflowed since this bit was last cleared. When written, sets the PMEVCNTR<n>_EL0 overflow bit to 1.

If ARMv8.5-PMU is implemented, MDCR_EL2.HLP and PMCR_EL0.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR<n>_EL0[31:0] or unsigned overflow of PMEVCNTR<n>_EL0[63:0].

This field resets to an architecturally UNKNOWN value.

D13.4.15 PMSELR_EL0, Performance Monitors Event Counter Selection Register

The PMSELR_EL0 characteristics are:

Purpose

Selects the current event counter PMEVCNTR<n>_EL0 or the cycle counter, CCNT.

PMSELR_EL0 is used in conjunction with PMXEVTYPER_EL0 to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCNTR_EL0, to determine the value of a selected event counter.

Configurations

AArch64 System register PMSELR_EL0[31:0] is architecturally mapped to AArch32 System register PMSELR[31:0].

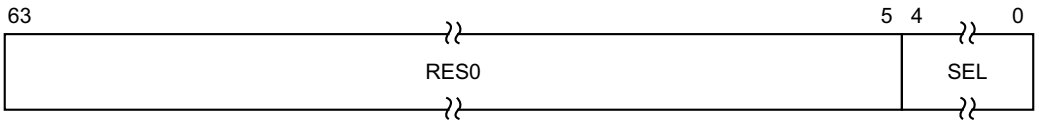
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSELR_EL0 is a 64-bit register.

Field descriptions

The PMSELR_EL0 bit assignments are:



Bits [63:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, PMEVCNTR<n>_EL0, where n is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 occurs.

This field can take any value from 0 (`0b00000`) to (PMCR.N)-1, or 31 (`0b11111`).

When PMSELR_EL0.SEL is `0b11111`, it selects the cycle counter and:

- A read of the PMXEVTYPER_EL0 returns the value of PMCCFILTR_EL0.
- A write of the PMXEVTYPER_EL0 writes to PMCCFILTR_EL0.
- A read or write of PMXEVCNTR_EL0 has CONSTRAINED UNPREDICTABLE effects. See PMXEVCNTR_EL0 for more details.

If this field is set to a value greater than or equal to the number of counters accessible at the current Exception level, but not equal to 31:

- Direct reads of this field return an UNKNOWN value.
- The results of access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE. See PMXEVTYPER_EL0 or PMXEVCNTR_EL0 for more details.

For information about the number of counters accessible at each Exception level, see MDCR_EL2.HPMN.

This field resets to an architecturally UNKNOWN value.

D13.4.16 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`. For more information, see SW_INCR.

Configurations

AArch64 System register PMSWINC_EL0[31:0] is architecturally mapped to AArch32 System register PMSWINC[31:0].

AArch64 System register PMSWINC_EL0[31:0] is architecturally mapped to External register PMSWINC_EL0[31:0].

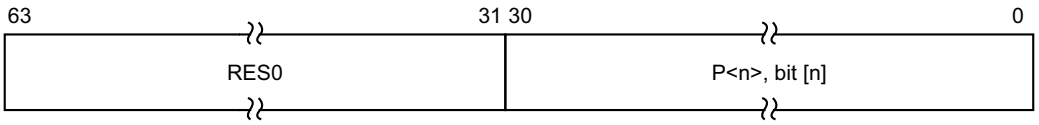
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSWINC_EL0 is a 64-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:



Bits [63:31]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 30

Event counter software increment bit for PMEVCNTR<n>_EL0.

If N is less than 31, then bits [30:N] are WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

`0b0` No action. The write to this bit is ignored.

`0b1` If PMEVCNTR<n>_EL0 is enabled and configured to count the software increment event, increments PMEVCNTR<n>_EL0 by 1. If PMEVCNTR<n>_EL0 is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MSR PMSWINC_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b100

```

D13.4.17 PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

Purpose

Enables or disables EL0 access to the Performance Monitors.

Configurations

AArch64 System register PMUSERENR_EL0[31:0] is architecturally mapped to AArch32 System register PMUSERENR[31:0].

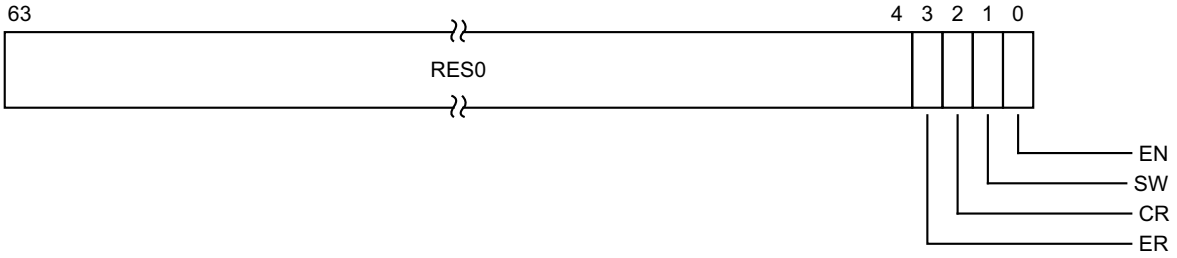
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMUSERENR_EL0 is a 64-bit register.

Field descriptions

The PMUSERENR_EL0 bit assignments are:



Bits [63:4]

Reserved, RES0.

ER, bit [3]

Event counter Read. Traps EL0 access to event counters to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.

In AArch64 state, trapped accesses are reported using EC syndrome value `0x18`.

In AArch64 state, trapped accesses are reported using EC syndrome value `0x03`.

`0b0` EL0 using AArch64: EL0 reads of the PMXEVCNTR_EL0 and PMEVCNTR<n>_EL0, and EL0 read/write accesses to the PMSELR_EL0, are trapped if PMUSERENR_EL0.EN is also 0.

EL0 using AArch32: EL0 reads of the PMXEVCNTR and PMEVCNTR<n>, and EL0 read/write accesses to the PMSELR, are trapped if PMUSERENR_EL0.EN is also 0.

`0b1` Overrides PMUSERENR_EL0.EN and enables RO access to PMXEVCNTR_EL0 and PMEVCNTR<n>_EL0, and RW access to PMSELR_EL0 and PMSELR at EL0.

This field resets to an architecturally UNKNOWN value.

CR, bit [2]

Cycle counter Read. Traps EL0 access to cycle counter reads to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.

In AArch64 state, trapped accesses are reported using EC syndrome value `0x18`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In AArch32 state, trapped MRC accesses are reported using EC syndrome value 0x03, trapped MRRC accesses are reported using EC syndrome value 0x04.

0b0 EL0 using AArch64: EL0 read accesses to the PMCCNTR_EL0 are trapped if PMUSERENR_EL0.EN is also 0.

EL0 using AArch32: EL0 read accesses to the PMCCNTR are trapped if PMUSERENR_EL0.EN is also 0.

0b1 Overrides PMUSERENR_EL0.EN and enables access to PMCCNTR_EL0 and PMCCNTR at EL0.

SW, bit [1]

Traps Software Increment writes to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.

In AArch64 state, trapped accesses are reported using EC syndrome value 0x18.

In AArch32 state, trapped accesses are reported using EC syndrome value 0x03.

0b0 EL0 using AArch64: EL0 writes to the PMSWINC_EL0 are trapped if PMUSERENR_EL0.EN is also 0.

EL0 using AArch32: EL0 writes to the PMSWINC are trapped if PMUSERENR_EL0.EN is also 0.

0b1 Overrides PMUSERENR_EL0.EN and enables access to PMSWINC_EL0 and PMSWINC at EL0.

This field resets to an architecturally UNKNOWN value.

EN, bit [0]

Traps EL0 accesses to the Performance Monitor registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states as follows:

- In AArch64 state, accesses to the following registers are reported using EC syndrome value 0x18.
  - PMCR_EL0. PMOVSCLR_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMXEVCNTR_EL0, PMUSERENR_EL0, PMCNTENSET_EL0, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0.
  - PMSWINC_EL0, MSR accesses only.
- In AArch32 state, MRC or MCR accesses to the following registers are reported using EC syndrome value 0x03 and MCRR or MRRC accesses are trapped to EL2 and reported using EC syndrome value 0x04
  - PMCR, PMOVSR, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMCNTENSET, PMCNTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.
  - PMSWINC, MCR accesses only.
- In Aarch32 state, MCRR or MRRC accesses to PMCCNTR are reported using EC syndrome value 0x04.
- If ARMv8.4-PMU is implemented, in Aarch64 state, PMMIR_EL1 and in AArch32 state, PMMIR.
- If ARMv8.1-PMU is implemented, in AArch32 state, PMCEID2, and PMCEID3.

0b0 While at EL0, Accesses to the specified registers at EL0 are trapped, unless overridden by one of PMUSERENR_EL0.{ER, CR, SW}.

0b1 While at EL0, software can access all of the specified registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The EL0 access is trapped only if the corresponding EL1 access is permitted. If PMUSERENR_EL0.EN is 0, write access to PMSWINC_EL0 and PMSWINC from EL0 are trapped, but read access is UNDEFINED.

The affected registers do not include PMINTENSET_EL1, PMINTENCLR_EL1, PMINTENSET, PMINTENCLR.

This field resets to an architecturally UNKNOWN value.

Accessing the PMUSERENR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMUSERENR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1110	0b000

D13.4.18 PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVCNTR_EL0 characteristics are:

Purpose

Reads or writes the value of the selected event counter, PMEVCNTR<n>_EL0. PMSELR_EL0.SEL determines which event counter is selected.

Configurations

AArch64 System register PMXEVCNTR_EL0[31:0] is architecturally mapped to AArch32 System register PMXEVCNTR[31:0].

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

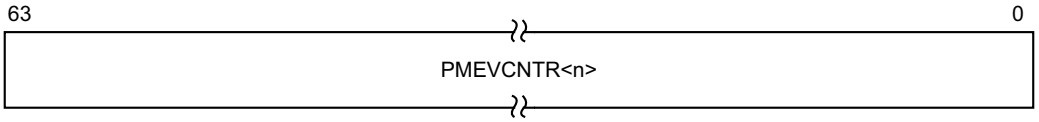
Attributes

PMXEVCNTR_EL0 is a 64-bit register.

Field descriptions

The PMXEVCNTR_EL0 bit assignments are:

When ARMv8.5-PMU is implemented:

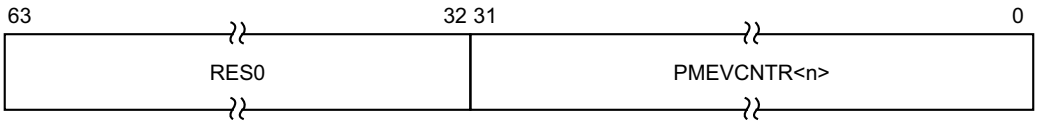


PMEVCNTR<n>, bits [63:0]

Value of the selected event counter, PMEVCNTR<n>_EL0, where n is the value stored in PMSELR_EL0.SEL.

This field resets to an architecturally UNKNOWN value.

Otherwise:



Bits [63:32]

Reserved, RES0.

PMEVCNTR<n>, bits [31:0]

Value of the selected event counter, PMEVCNTR<n>_EL0, where n is the value stored in PMSELR_EL0.SEL.

This field resets to an architecturally UNKNOWN value.

Accessing the PMXEVCNTR_EL0

If PMSELR_EL0.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- If EL2 is implemented and enabled in the current Security state, and PMSELR_EL0.SEL is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.{ER,EN}.

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters. See MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMXEVCNTR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1101	0b010

D13.4.19 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

Purpose

When PMSELR_EL0.SEL selects an event counter, this accesses a PMEVTYPER<n>_EL0 register. When PMSELR_EL0.SEL selects the cycle counter, this accesses PMCCFILTR_EL0.

Configurations

AArch64 System register PMXEVTYPER_EL0[31:0] is architecturally mapped to AArch32 System register PMXEVTYPER[31:0].

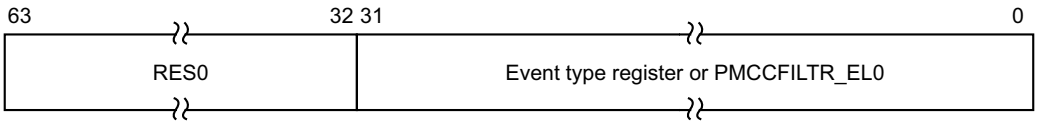
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMXEVTYPER_EL0 is a 64-bit register.

Field descriptions

The PMXEVTYPER_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

Event type register or PMCCFILTR_EL0, bits [31:0]

When PMSELR_EL0.SEL == 31, this register accesses PMCCFILTR_EL0.

Otherwise, this register accesses PMEVTYPER<n>_EL0 where n is the value in PMSELR_EL0.SEL.

This field resets to an architecturally UNKNOWN value.

Accessing the PMXEVTYPER_EL0

If PMSELR_EL0.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVTYPER_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`
- Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR_EL0.SEL is 31.
- If EL2 is implemented and enabled in the current Security state, PMSELR_EL0 is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.EN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters. See MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMXEVTYPER_EL0

D13.5 Activity Monitors registers

This section lists the Activity Monitors registers in AArch64.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D13.5.1 AMCFGR_EL0, Activity Monitors Configuration Register

The AMCFGR_EL0 characteristics are:

Purpose

Global configuration register for the activity monitors.

Provides information on supported features, the number of counter groups implemented, the total number of activity monitor event counters implemented, and the size of the counters. AMCFGR_EL0 is applicable to both the architected and the auxiliary counter groups.

Configurations

AArch64 System register AMCFGR_EL0[31:0] is architecturally mapped to AArch32 System register AMCFGR[31:0].

AArch64 System register AMCFGR_EL0[31:0] is architecturally mapped to External register AMCFGR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCFGR_EL0 are UNDEFINED.

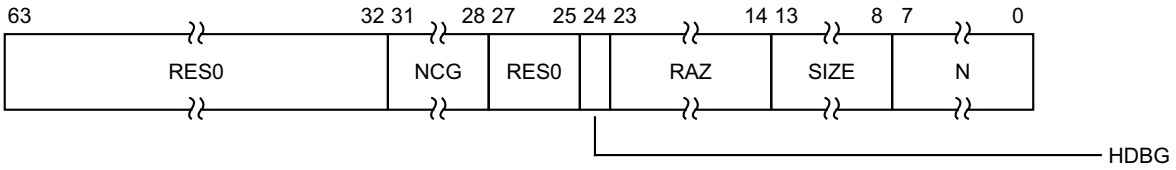
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCFGR_EL0 is a 64-bit register.

Field descriptions

The AMCFGR_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

NCG, bits [31:28]

Defines the number of counter groups.

The number of implemented counter groups is defined as [AMCFGR_EL0.NCG + 1].

If the number of implemented auxiliary activity monitor event counters is zero, this field has a value of `0b0000`. Otherwise, this field has a value of `0b0001`.

Bits [27:25]

Reserved, RES0.

HDBG, bit [24]

Halt-on-debug supported.

From Armv8, this feature must be supported, and so this bit is `0b1`.

`0b0` AMCR_EL0.HDBG is RES0.

`0b1` AMCR_EL0.HDBG is read/write.

Bits [23:14]

Reserved, RAZ.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SIZE, bits [13:8]

Defines the size of activity monitor event counters.

The size of the activity monitor event counters implemented by the activity monitors Extension is defined as [AMCFGR_EL0.SIZE + 1].

From Armv8, the counters are 64-bit, and so this field is `0b111111`.

Note

Software also uses this field to determine the spacing of counters in the memory-map. From Armv8, the counters are at doubleword-aligned addresses.

N, bits [7:0]

Defines the number of activity monitor event counters.

The total number of counters implemented in all groups by the Activity Monitors Extension is defined as [AMCFGR_EL0.N + 1].

Accessing the AMCFGR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, AMCFGR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0010	0b001

```
if PSTATE.EL == EL0 then
    if !ELUsingAArch32(EL1) && AMUSERENR_EL0.EN == '0' then
        if EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    elsif EL2Enabled() && !ELUsingAArch32(EL2) && CPTR_EL2.TAM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif HaveEL(EL3) && !ELUsingAArch32(EL3) && CPTR_EL3.TAM == '1' then
        AArch64.SystemAccessTrap(EL3, 0x18);
    else

D13.5.2 AMCGCR_EL0, Activity Monitors Counter Group Configuration Register

The AMCGCR_EL0 characteristics are:

Purpose

Provides information on the number of activity monitor event counters implemented within each counter group.

Configurations

AArch64 System register AMCGCR_EL0[31:0] is architecturally mapped to AArch32 System register AMCGCR[31:0].

AArch64 System register AMCGCR_EL0[31:0] is architecturally mapped to External register AMCGCR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCGCR_EL0 are UNDEFINED.

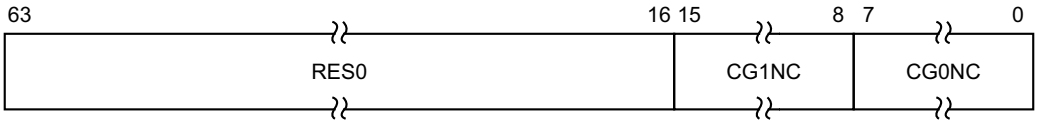
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCGCR_EL0 is a 64-bit register.

Field descriptions

The AMCGCR_EL0 bit assignments are:



Bits [63:16]

Reserved, RES0.

CG1NC, bits [15:8]

Counter Group 1 Number of Counters. The number of counters in the auxiliary counter group.

In AMUv1, the permitted range of values is `0x0` to `0x10`.

CG0NC, bits [7:0]

Counter Group 0 Number of Counters. The number of counters in the architected counter group.

In AMUv1, the value of this field is `0x4`.

Accessing the AMCGCR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, AMCGCR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0010	0b010

D13.5.3 AMCNTENCLR0_EL0, Activity Monitors Count Enable Clear Register 0

The AMCNTENCLR0_EL0 characteristics are:

Purpose

Disable control bits for the architected activity monitors event counters, AMEVCNTR0<n>_EL0.

Configurations

AArch64 System register AMCNTENCLR0_EL0[31:0] is architecturally mapped to AArch32 System register AMCNTENCLR0[31:0].

AArch64 System register AMCNTENCLR0_EL0[31:0] is architecturally mapped to External register AMCNTENCLR0[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR0_EL0 are UNDEFINED.

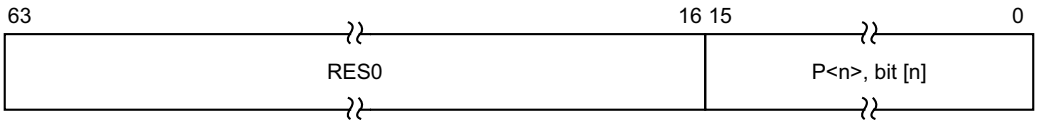
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCNTENCLR0_EL0 is a 64-bit register.

Field descriptions

The AMCNTENCLR0_EL0 bit assignments are:



Bits [63:16]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 15

Activity monitor event counter disable bit for AMEVCNTR0<n>_EL0.

Bits [31:16] are RES0. Bits [15:N] are RAZ/WI. N is the value in AMCGCR_EL0.CG0NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR0<n>_EL0 is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR0<n>_EL0 is enabled. When written, disables AMEVCNTR0<n>_EL0.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENCLR0_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

D13.5.4 AMCNTENCLR1_EL0, Activity Monitors Count Enable Clear Register 1

The AMCNTENCLR1_EL0 characteristics are:

Purpose

Disable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>_EL0.

Configurations

AArch64 System register AMCNTENCLR1_EL0[31:0] is architecturally mapped to AArch32 System register AMCNTENCLR1[31:0].

AArch64 System register AMCNTENCLR1_EL0[31:0] is architecturally mapped to External register AMCNTENCLR1[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR1_EL0 are UNDEFINED.

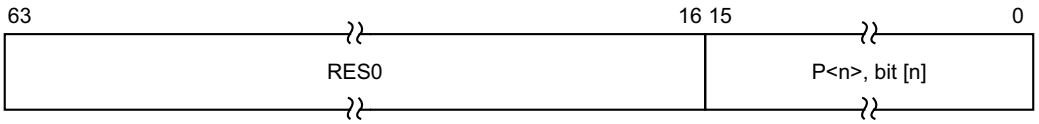
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCNTENCLR1_EL0 is a 64-bit register.

Field descriptions

The AMCNTENCLR1_EL0 bit assignments are:



Bits [63:16]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 15

Activity monitor event counter disable bit for AMEVCNTR1<n>_EL0.

Bits [31:16] are RES0. Bits [15:N] are RAZ/WI. N is the value in AMCGCR_EL0.CG1NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR1<n>_EL0 is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR1<n>_EL0 is enabled. When written, disables AMEVCNTR1<n>_EL0.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENCLR1_EL0

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

D13.5.7 AMCR_EL0, Activity Monitors Control Register

The AMCR_EL0 characteristics are:

Purpose

Global control register for the activity monitors implementation. AMCR_EL0 is applicable to both the architected and the auxiliary counter groups.

Configurations

AArch64 System register AMCR_EL0[31:0] is architecturally mapped to AArch32 System register AMCR[31:0].

AArch64 System register AMCR_EL0[31:0] is architecturally mapped to External register AMCR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCR_EL0 are UNDEFINED.

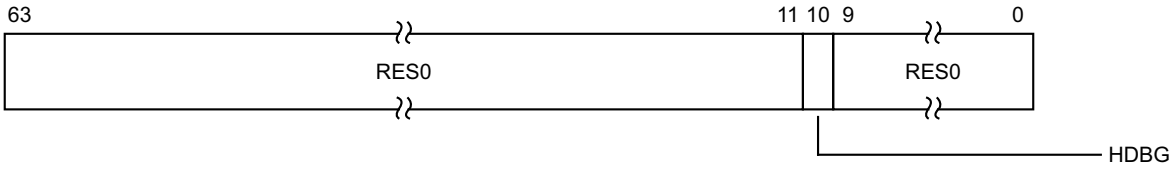
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCR_EL0 is a 64-bit register.

Field descriptions

The AMCR_EL0 bit assignments are:



Bits [63:11]

Reserved, RES0.

HDBG, bit [10]

This bit controls whether activity monitor counting is halted when the PE is halted in Debug state.

`0b0` Activity monitors do not halt counting when the PE is halted in Debug state.

`0b1` Activity monitors halt counting when the PE is halted in Debug state.

Bits [9:0]

Reserved, RES0.

Accessing the AMCR_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

D13.5.8 AMEVCNTR0<n>_EL0, Activity Monitors Event Counter Registers 0, n = 0 - 15

The AMEVCNTR0<n>_EL0 characteristics are:

Purpose

Provides access to the architected activity monitor event counters.

Configurations

AArch64 System register AMEVCNTR0<n>_EL0[63:0] is architecturally mapped to AArch32 System register AMEVCNTR0<n>[63:0].

AArch64 System register AMEVCNTR0<n>_EL0[63:0] is architecturally mapped to External register AMEVCNTR0<n>[63:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR0<n>_EL0 are UNDEFINED.

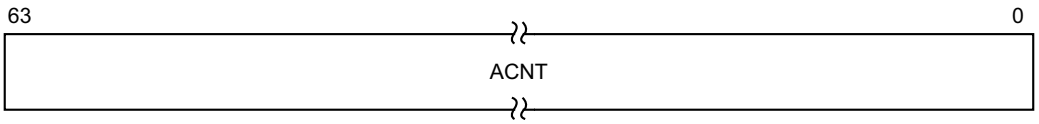
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMEVCNTR0<n>_EL0 is a 64-bit register.

Field descriptions

The AMEVCNTR0<n>_EL0 bit assignments are:



ACNT, bits [63:0]

Architected activity monitor event counter n.

Value of architected activity monitor event counter n, where n is the number of this register and is a number from 0 to 15.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to `0`.

Accessing the AMEVCNTR0<n>_EL0

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

Note

AMCGCR_EL0.CG0NC identifies the number of architected activity monitor event counters.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.5.11 AMEVTYPER1<n>_EL0, Activity Monitors Event Type Registers 1, n = 0 - 15

The AMEVTYPER1<n>_EL0 characteristics are:

Purpose

Provides information on the events that an auxiliary activity monitor event counter AMEVCNTR1<n>_EL0 counts.

Configurations

AArch64 System register AMEVTYPER1<n>_EL0[31:0] is architecturally mapped to AArch32 System register AMEVTYPER1<n>[31:0].

AArch64 System register AMEVTYPER1<n>_EL0[31:0] is architecturally mapped to External register AMEVTYPER1<n>[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPER1<n>_EL0 are UNDEFINED.

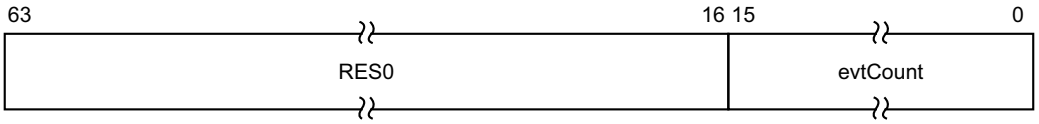
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMEVTYPER1<n>_EL0 is a 64-bit register.

Field descriptions

The AMEVTYPER1<n>_EL0 bit assignments are:



Bits [63:16]

Reserved, RES0.

evtCount, bits [15:0]

Event to count. The event number of the event that is counted by the auxiliary activity monitor event counter AMEVCNTR1<n>_EL0.

It is IMPLEMENTATION DEFINED what values are supported by each counter.

If software writes a value to this field which is not supported by the corresponding counter AMEVCNTR1<n>_EL0, then:

- It is UNPREDICTABLE which event will be counted.
- The value read back is UNKNOWN.

The event counted by AMEVCNTR1<n>_EL0 might be fixed at implementation. In this case, the field is read-only and writes are UNDEFINED.

If the corresponding counter AMEVCNTR1<n>_EL0 is enabled, writes to this register have UNPREDICTABLE results.

Accessing the AMEVTYPER1<n>_EL0

If <n> is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVTYPER1<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

D13.5.12 AMUSERENR_EL0, Activity Monitors User Enable Register

The AMUSERENR_EL0 characteristics are:

Purpose

Global user enable register for the activity monitors. Enables or disables EL0 access to the activity monitors. AMUSERENR_EL0 is applicable to both the architected and the auxiliary counter groups.

Configurations

AArch64 System register AMUSERENR_EL0[31:0] is architecturally mapped to AArch32 System register AMUSERENR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMUSERENR_EL0 are UNDEFINED.

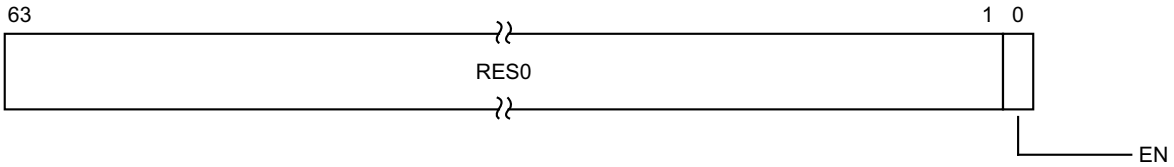
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMUSERENR_EL0 is a 64-bit register.

Field descriptions

The AMUSERENR_EL0 bit assignments are:



Bits [63:1]

Reserved, RES0.

EN, bit [0]

Traps EL0 accesses to the activity monitors registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped, reported using EC syndrome value `0x18`:
  - AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0<n>_EL0, AMEVCNTR1<n>_EL0, AMEVTYPER0<n>_EL0, and AMEVTYPER1<n>_EL0.
- In AArch32 state, MRC and MCR accesses to the following registers are trapped and reported using EC syndrome value `0x03`, MRRC and MCRR accesses are trapped and reported using EC syndrome value `0x04`:
  - AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVCNTR0<n>, AMEVCNTR1<n>, AMEVTYPER0<n>, and AMEVTYPER1<n>.

`0b0` EL0 accesses to the activity monitors registers are trapped.

`0b1` This control does not cause any instructions to be trapped. Software can access all activity monitor registers at EL0.

Note

- AMUSERENR_EL0 can always be read at EL0 and is not governed by this bit.

D13.6 Statistical Profiling Extension registers

This section lists the Statistical Profiling Extension registers in AArch64.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D13.6.1 PMBIDR_EL1, Profiling Buffer ID Register

The PMBIDR_EL1 characteristics are:

Purpose

Provides information to software as to whether the buffer can be programmed at the current Exception level.

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMBIDR_EL1 are UNDEFINED.

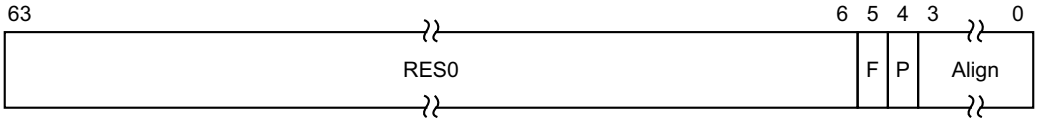
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMBIDR_EL1 is a 64-bit register.

Field descriptions

The PMBIDR_EL1 bit assignments are:



Bits [63:6]

Reserved, RES0.

F, bit [5]

Flag Updates. Defines whether the address translation performed by the Profiling Buffer manages the Access Flag and dirty state.

`0b0` Hardware management of the Access Flag and dirty state for accesses made by the Statistical Profiling Extension is always disabled for all translation stages.

`0b1` Hardware management for the Access Flag and dirty state for accesses made by the Statistical Profiling Extension is controlled in the same way as explicit memory accesses in the owning translation regime.

If hardware management of the Access Flag is disabled for a stage of translation, an access to Page or Block with the Access flag bit not set in the descriptor will generate an Access Flag fault.

If hardware management of the dirty state is disabled for a stage of translation, an access to a Page or Block will ignore the Dirty Bit Modifier in the descriptor might generate a Permission fault, depending on the values of the access permission bits in the descriptor.

P, bit [4]

When ARMv8.4-SecEL2 is implemented:

Programming not allowed. The Profiling Buffer is owned by a higher Exception level or the other Security state.

`0b0` Profiling Buffer is owned by the current or a lower Exception level in the current Security state.

`0b1` Profiling Buffer is owned by a higher Exception level or the other Security state.

The value read from this field depends on the current Exception level and the values of MDCR_EL3.NSPB and MDCR_EL2.E2PB:

- If MDCR_EL3.NSPB == `0b00` or MDCR_EL3.NSPB == `0b01`, this bit reads as one from Non-secure EL2 and Non-secure EL1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If MDCR_EL3.NSPB == 0b10 or MDCR_EL3.NSPB == 0b11, this bit reads as one from Secure EL1 and, if Secure EL2 is implemented and enabled, Secure EL2.
- If MDCR_EL2.E2PB == 0b00, this bit reads as one from Non-secure EL1, and if Secure EL2 is implemented and enabled, also from Secure EL1.
- Otherwise, this bit reads as zero.

Otherwise:

Programming not allowed. The Profiling Buffer is owned by a higher Exception level or the other Security state.

0b0 Profiling Buffer is owned by the current or a lower Exception level in the current Security state.

0b1 Profiling Buffer is owned by a higher Exception level or the other Security state.

The value read from this field depends on the current Exception level and the values of MDCR_EL3.NSPB and MDCR_EL2.E2PB:

- If MDCR_EL3.NSPB == 0b00 or MDCR_EL3.NSPB == 0b01, this bit reads as one from EL2 and Non-secure EL1.
- If MDCR_EL3.NSPB == 0b10 or MDCR_EL3.NSPB == 0b11, this bit reads as one from Secure EL1.
- If MDCR_EL2.E2PB == 0b00, this bit reads as one from Non-secure EL1.
- Otherwise, this bit reads as zero.

Align, bits [3:0]

Defines the minimum alignment constraint for PMBPTR_EL1. If this field is non-zero, then the PE must pad every record up to a multiple of this size.

0b0000 Byte

0b0001 Halfword.

0b0010 Word.

0b0011 Doubleword.

0b0100 16 Bytes.

0b0101 32 Bytes.

0b0110 64 Bytes.

0b0111 128 Bytes.

0b1000 256 Bytes.

0b1001 512 Bytes.

0b1010 1KB.

0b1011 2KB.

For more information, see *Restrictions on the current write pointer* on page D9-2750.

Accessing the PMBIDR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMBIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1001	0b1010	0b111

D13.6.2 PMBLIMITR_EL1, Profiling Buffer Limit Address Register

The PMBLIMITR_EL1 characteristics are:

Purpose

Defines the upper limit for the profiling buffer, and enables the profiling buffer

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMBLIMITR_EL1 are UNDEFINED.

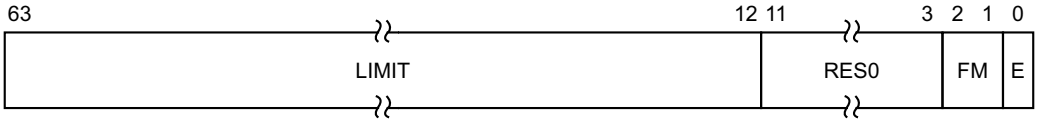
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMBLIMITR_EL1 is a 64-bit register.

Field descriptions

The PMBLIMITR_EL1 bit assignments are:



LIMIT, bits [63:12]

Limit address. PMBLIMITR_EL1.LIMIT:Zeros(12) is the address of the first byte in memory after the last byte in the profiling buffer. If the smallest implemented translation granule is not 4KB, then bits[N-1:12] are RES0, where N is the IMPLEMENTATION DEFINED value, Log_2(smallest implemented translation granule).

This field resets to an architecturally UNKNOWN value.

Bits [11:3]

Reserved, RES0.

FM, bits [2:1]

Fill mode

`0b00` Stop collection and raise maintenance interrupt on buffer fill.

All other values are reserved. If this field is programmed with a reserved value, the PE behaves as if this field has a defined value, other than for a direct read of the register. Software must not rely on the behavior of reserved values, as they might change in a future version of the architecture.

This field resets to an architecturally UNKNOWN value.

E, bit [0]

Profiling Buffer enable

`0b0` All output is discarded.

`0b1` Profiling buffer enabled.

On a Warm reset, this field resets to `0`.

Accessing the PMBLIMITR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

D13.6.3 PMBPTR_EL1, Profiling Buffer Write Pointer Register

The PMBPTR_EL1 characteristics are:

Purpose

Defines the current write pointer for the profiling buffer.

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMBPTR_EL1 are UNDEFINED.

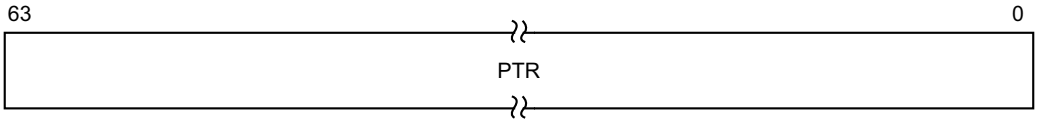
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMBPTR_EL1 is a 64-bit register.

Field descriptions

The PMBPTR_EL1 bit assignments are:



PTR, bits [63:0]

Current write address. Defines the virtual address of the next entry to be written to the buffer.

The architecture places restrictions on the values software can write to the pointer. For more information see *Restrictions on the current write pointer* on page D9-2750.

Note

As a result, an implementation might treat some of bits[M:0], where M is defined by PMBIDR_EL1.Align, as RES0.

On a management interrupt, PMBPTR_EL1 is frozen.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMBPTR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMBPTR_EL1

D13.6.4 PMBSR_EL1, Profiling Buffer Status/syndrome Register

The PMBSR_EL1 characteristics are:

Purpose

Provides syndrome information to software when the buffer is disabled because the management interrupt has been raised.

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMBSR_EL1 are UNDEFINED.

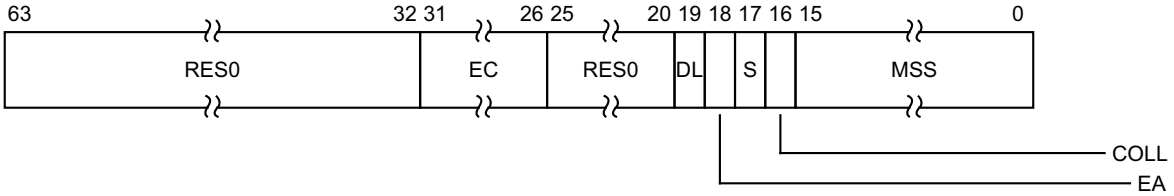
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMBSR_EL1 is a 64-bit register.

Field descriptions

The PMBSR_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

EC, bits [31:26]

Exception class

Top-level description of the cause of the buffer management event

EC == 0b100100

Stage 1 Data Abort on write to Profiling Buffer.

See MSS encoding for a Data Abort or stage 2 Data Abort on write to buffer.

EC == 0b100101

Stage 2 Data Abort on write to Profiling Buffer.

See MSS encoding for a Data Abort or stage 2 Data Abort on write to buffer.

EC == 0b000000

Other buffer management event. All buffer management events other than those described by other defined Exception class codes.

See MSS encoding for other buffer management event.

All other values are reserved. Reserved values might be defined in a future version of the architecture.

Writing a reserved value to this field will make the value of this field UNKNOWN. Values that are not supported act as reserved values when writing to this register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [25:20]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DL, bit [19]

Partial record lost.

Following a buffer management event other than an asynchronous External abort, indicates whether the last record written to the Profiling Buffer is complete.

`0b0` PMBPTR_EL1 points to the first byte after the last complete record written to the Profiling Buffer.

`0b1` Part of a record was lost because of a buffer management event or synchronous External abort. PMBPTR_EL1 might not point to the first byte after the last complete record written to the buffer, and so restarting collection might result in a data record stream that software cannot parse. All records prior to the last record have been written to the buffer.

When the buffer management event was because of an asynchronous external abort, this bit is set to 1 and software must not assume that any valid data has been written to the Profiling Buffer.

This bit is RES0 if the PE never sets this bit as a result of a buffer management event caused by an asynchronous External abort.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [18]

External abort.

`0b0` An external abort has not been asserted.

`0b1` An external abort has been asserted and detected by the Statistical Profiling Extension.

This bit is RES0 if the PE never sets this bit as the result of an External abort.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [17]

Service

`0b0` PMBIRQ is not asserted.

`0b1` PMBIRQ is asserted. All profiling data has either been written to the buffer or discarded.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

COLL, bit [16]

Collision detected.

`0b0` No collision events detected.

`0b1` At least one collision event was recorded.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

MSS, bits [15:0]

Management Event Specific Syndrome.

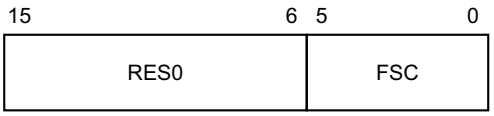
Contains syndrome specific to the management event.

The syndrome contents for each management event are described in the following sections.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MSS encoding for a Data Abort or stage 2 Data Abort on write to buffer



Bits [15:6]

Reserved, RES0.

FSC, bits [5:0]

Fault status code

`0b0000xx` Address Size fault. Bits [1:0] encode the level.

`0b0001xx` Translation fault. Bits [1:0] encode the level.

`0b0010xx` Access Flag fault. Bits [1:0] encode the level.

`0b0011xx` Permission fault. Bits [1:0] encode the level.

`0b010000` Synchronous External abort on write.

`0b0101xx` Synchronous External abort on translation table walk or hardware update of translation table. Bits [1:0] encode the level.

`0b010001` Asynchronous External abort on write.

`0b100001` Alignment fault.

`0b110000` TLB Conflict fault.

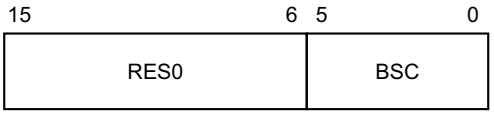
All other values are reserved. Reserved values might be defined in a future version of the architecture.

Writing a reserved value to this field will make the value of this field UNKNOWN. Values that are not supported act as reserved values when writing to this register.

It is IMPLEMENTATION DEFINED whether each of the Access Flag fault, asynchronous External abort and synchronous External abort, Alignment fault, and TLB Conflict abort values can be generated by the PE. For more information see *Faults and watchpoints* on page D9-2755.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

MSS encoding for other buffer management event



Bits [15:6]

Reserved, RES0.

BSC, bits [5:0]

Buffer status code

`0b000000` Buffer not filled

`0b000001` Buffer filled

All other values are reserved. Reserved values might be defined in a future version of the architecture.

Writing a reserved value to this field will make the value of this field UNKNOWN. Values that are not supported act as reserved values when writing to this register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

D13.6.5 PMSCR_EL1, Statistical Profiling Control Register (EL1)

The PMSCR_EL1 characteristics are:

Purpose

Provides EL1 controls for Statistical Profiling

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSCR_EL1 are UNDEFINED.

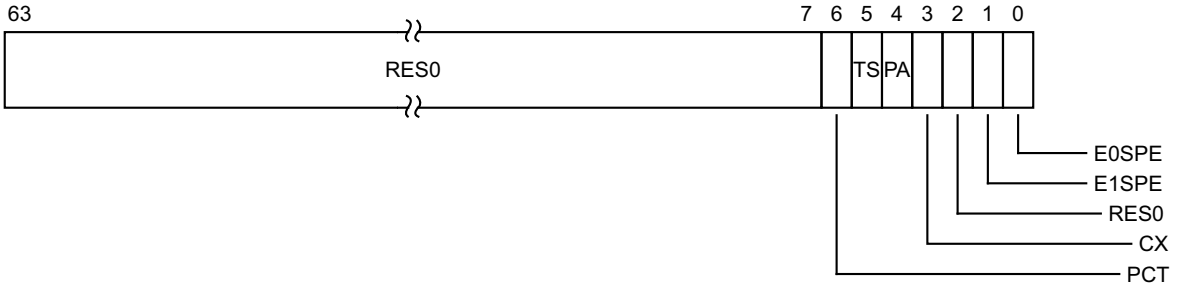
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSCR_EL1 is a 64-bit register.

Field descriptions

The PMSCR_EL1 bit assignments are:



Bits [63:7]

Reserved, RES0.

PCT, bit [6]

When HaveEL(EL2):

Physical Timestamp.

If timestamp sampling is enabled, determines which counter is collected.

`0b0` Virtual counter, CNTVCT_EL0, is collected.

`0b1` Physical counter, CNTPCT_EL0, is collected.

If EL2 is implemented and enabled in the current Security state:

- If MDCR_EL2.E2PB != `0b00`, this bit is combined with PMSCR_EL2.PCT to determine which counter is collected. For more information, see *Controlling the data that is collected on page D9-2748*
- If MDCR_EL2.E2PB == `0b00`, this bit is ignored by the PE.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

TS, bit [5]

Timestamp Enable.

`0b0` Timestamp sampling disabled.

`0b1` Timestamp sampling enabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when MDCR_EL2.E2PB == 0b00.

This field resets to an architecturally UNKNOWN value.

PA, bit [4]

Physical Address Sample Enable.

0b0 Physical addresses are not collected.

0b1 Physical addresses are collected.

If EL2 is implemented and enabled in the current Security state:

- If MDCR_EL2.E2PB != 0b00, this bit is combined with PMSCR_EL2.PA to determine which address is collected. For more information, see *Controlling the data that is collected* on page D9-2748.
- If MDCR_EL2.E2PB == 0b00, this bit is ignored by the PE.

This field resets to an architecturally UNKNOWN value.

CX, bit [3]

CONTEXTIDR_EL1 Sample Enable.

0b0 CONTEXTIDR_EL1 is not collected.

0b1 CONTEXTIDR_EL1 is collected.

If EL2 is implemented and enabled in the current Security state:

- If the PE is at EL2, this bit is ignored by the PE.
- If HCR_EL2.TGE == 1, this bit is ignored by the PE.

This field resets to an architecturally UNKNOWN value.

Bit [2]

Reserved, RES0.

E1SPE, bit [1]

EL1 Statistical Profiling Enable.

0b0 Sampling disabled at EL1.

0b1 Sampling enabled at EL1.

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 1.

This field resets to an architecturally UNKNOWN value.

E0SPE, bit [0]

EL0 Statistical Profiling Enable. Controls sampling at EL0 when HCR_EL2.TGE == 0 or if EL2 is disabled or not implemented.

0b0 Sampling disabled at EL0.

0b1 Sampling enabled at EL0.

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 1.

This field resets to an architecturally UNKNOWN value.

D13.6.6 PMSCR_EL2, Statistical Profiling Control Register (EL2)

The PMSCR_EL2 characteristics are:

Purpose

Provides EL2 controls for Statistical Profiling

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSCR_EL2 are UNDEFINED.

This register has no effect if EL2 is not enabled in the current Security state.

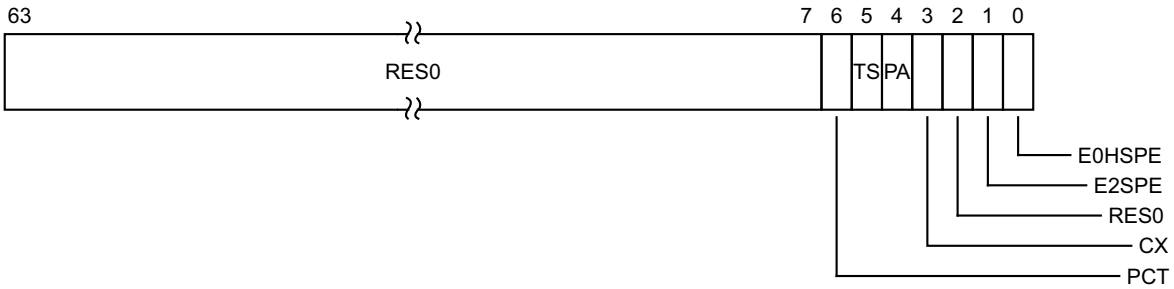
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSCR_EL2 is a 64-bit register.

Field descriptions

The PMSCR_EL2 bit assignments are:



Bits [63:7]

Reserved, RES0.

PCT, bit [6]

Physical Timestamp.

If timestamp sampling is enabled, determines which counter is collected.

`0b0` Virtual counter, CNTVCT_EL0, is collected.

`0b1` Physical counter, CNTPCT_EL0, is collected.

If MDCR_EL2.E2PB != `0b00`, this bit is combined with PMSCR_EL1.PCT to determine which counter is collected. For more information, see *Controlling the data that is collected* on page D9-2748.

If EL2 is disabled in the current Security state, this bit is ignored. If EL2 is not implemented, the PE behaves as if this bit is set to 1, other than for a direct read of the register.

This field resets to an architecturally UNKNOWN value.

TS, bit [5]

Timestamp Enable.

`0b0` Timestamp sampling disabled.

`0b1` Timestamp sampling enabled.

If EL2 is disabled in the current Security state, or if MDCR_EL2.E2PB != `0b00`, this bit is ignored.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PA, bit [4]

Physical Address Sample Enable.

0b0 Physical addresses are not collected.

0b1 Physical addresses are collected.

If MDCR_EL2.E2PB != 0b00, this bit is combined with PMSCR_EL1.PA to determine which address is collected. For more information, see *Controlling the data that is collected* on page D9-2748.

If EL2 is disabled in the current Security state, this bit is ignored. If EL2 is not implemented, the PE behaves as if this bit is set to 1, other than for a direct read of the register.

This field resets to an architecturally UNKNOWN value.

CX, bit [3]

CONTEXTIDR_EL2 Sample Enable.

0b0 CONTEXTIDR_EL2 is not collected.

0b1 CONTEXTIDR_EL2 is collected.

If EL2 is disabled in the current Security state, this bit is ignored by the PE.

This field resets to an architecturally UNKNOWN value.

Bit [2]

Reserved, RES0.

E2SPE, bit [1]

EL2 Statistical Profiling Enable.

0b0 Sampling disabled at EL2.

0b1 Sampling enabled at EL2.

This bit is RES0 if MDCR_EL2.E2PB != 0b00.

If EL2 is disabled in the current Security state, this bit is ignored by the PE.

This field resets to an architecturally UNKNOWN value.

E0HSPE, bit [0]

EL0 Statistical Profiling Enable.

0b0 Sampling disabled at EL0.

0b1 Sampling enabled at EL0.

If MDCR_EL2.E2PB != 0b00, this bit is RES0.

If EL2 is implemented and enabled in the current Security state, this bit is ignored by the PE when HCR_EL2.TGE == 0.

This field resets to an architecturally UNKNOWN value.

D13.6.7 PMSEVFR_EL1, Sampling Event Filter Register

The PMSEVFR_EL1 characteristics are:

Purpose

Controls sample filtering by events. The overall filter is the logical AND of these filters. For example, if E[3] and E[5] are both set to 1, only samples that have both event 3 (Level 1 unified or data cache refill) and event 5 set (TLB walk) are recorded

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSEVFR_EL1 are UNDEFINED.

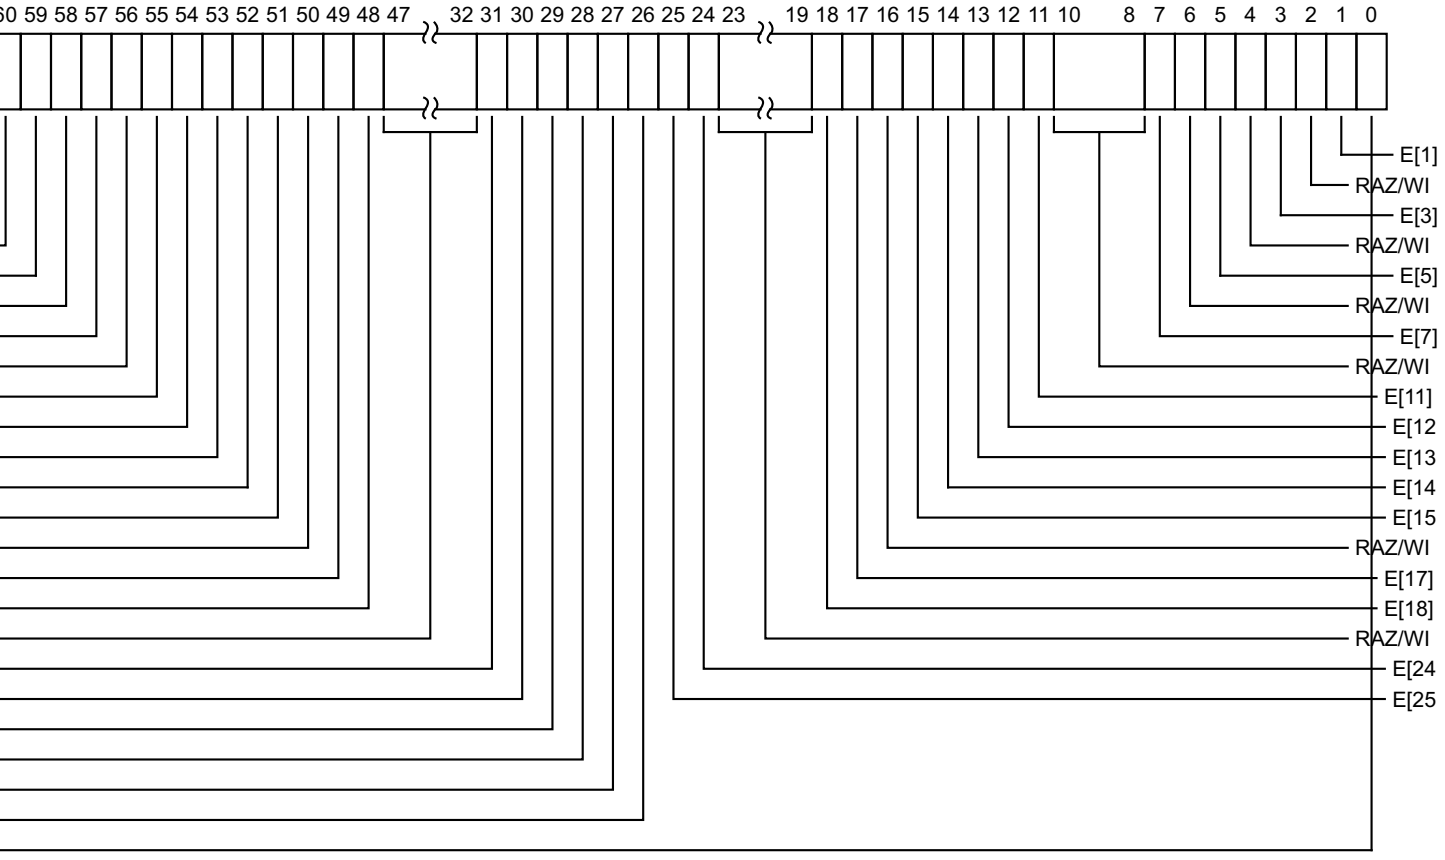
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSEVFR_EL1 is a 64-bit register.

Field descriptions

The PMSEVFR_EL1 bit assignments are:



E[<z>], bit [z], for z = 48 to 63

E[<z>] is the event filter for event <z>. If event <z> is not implemented, or filtering on event <z> is not supported, the corresponding bit is RAZ/WI.

`0b0` Event <z> is ignored.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 Do not record samples that have event <z> == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0

This field resets to an architecturally UNKNOWN value.

Bits [47:32]

Reserved, RAZ/WI.

E[<y>], bit [y], for y = 24 to 31

E[<y>] is the event filter for event <y>. If event <y> is not implemented, or filtering on event <y> is not supported, the corresponding bit is RAZ/WI.

0b0 Event <y> is ignored.

0b1 Do not record samples that have event <y> == 0.

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0

This field resets to an architecturally UNKNOWN value.

Bits [23:19]

Reserved, RAZ/WI.

E[18], bit [18]

When ARMv8.3-SPE is implemented and SVE is implemented:

Empty predicate.

0b0 Empty predicate event is ignored.

0b1 Do not record samples that have the Empty predicate event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAZ/WI.

E[17], bit [17]

When ARMv8.3-SPE is implemented and SVE is implemented:

Partial predicate.

0b0 Partial predicate event is ignored.

0b1 Do not record samples that have the Partial predicate event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAZ/WI.

Bit [16]

Reserved, RAZ/WI.

E[<x>], bit [x], for x = 12 to 15

E[<x>] is the event filter for event <x>. If event <x> is not implemented, or filtering on event <x> is not supported, the corresponding bit is RAZ/WI.

0b0 Event <x> is ignored.

0b1 Do not record samples that have event <x> == 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

An IMPLEMENTATION DEFINED event might be recorded as a multi-bit field. In this case, if the corresponding bits of PMSEVFR_EL1 define an IMPLEMENTATION DEFINED filter for the event.

This field is ignored by the PE when PMSFCR_EL1.FE == 0

This field resets to an architecturally UNKNOWN value.

E[11], bit [11]

When ARMv8.3-SPE is implemented:

Alignment.

0b0 Alignment event is ignored.

0b1 Do not record samples that have the Alignment event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAZ/WI.

Bits [10:8]

Reserved, RAZ/WI.

E[7], bit [7]

Mispredicted.

0b0 Mispredicted event is ignored.

0b1 Do not record samples that have the Mispredicted event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

This field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RAZ/WI.

E[5], bit [5]

TLB walk.

0b0 TLB walk event is ignored.

0b1 Do not record samples that have the TLB walk event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

This field resets to an architecturally UNKNOWN value.

Bit [4]

Reserved, RAZ/WI.

E[3], bit [3]

Level 1 data or unified cache refill.

0b0 Level 1 data or unified cache refill event is ignored.

0b1 Do not record samples that have the Level 1 data or unified cache refill event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

This field resets to an architecturally UNKNOWN value.

Bit [2]

Reserved, RAZ/WI.

E[1], bit [1]

When the PE supports sampling of speculative instructions:

Architecturally retired.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the PE supports sampling of speculative instructions:

0b0 Architecturally retired event is ignored.

0b1 Do not record samples that have the Architecturally retired event == 0.

This bit is ignored by the PE when PMSFCR_EL1.FE == 0.

If the PE does not support the sampling of speculative instructions, or always discards the sample record for speculative instructions, this bit reads as an UNKNOWN value and the PE ignores its value.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, UNKNOWN.

Bit [0]

Reserved, RAZ/WI.

D13.6.8 PMSFCR_EL1, Sampling Filter Control Register

The PMSFCR_EL1 characteristics are:

Purpose

Controls sample filtering. The filter is the logical AND of the FL, FT and FE bits. For example, if FE == 1 and FT == 1 only samples including the selected operation types and the selected events will be recorded

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSFCR_EL1 are UNDEFINED.

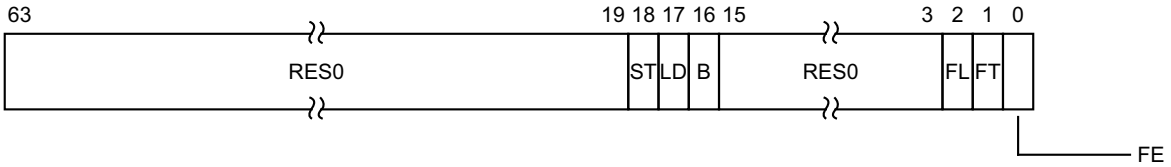
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSFCR_EL1 is a 64-bit register.

Field descriptions

The PMSFCR_EL1 bit assignments are:



Bits [63:19]

Reserved, RES0.

ST, bit [18]

Store filter enable

0b0 Do not record store operations

0b1 Record all store operations, including vector stores and all atomic operations

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

This field resets to an architecturally UNKNOWN value.

LD, bit [17]

Load filter enable

0b0 Do not record load operations

0b1 Record all load operations, including vector loads and atomic operations that return data

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

This field resets to an architecturally UNKNOWN value.

B, bit [16]

Branch filter enable

0b0 Do not record branch and exception return operations

0b1 Record all branch and exception return operations

This bit is ignored by the PE when PMSFCR_EL1.FT == 0.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [15:3]

Reserved, RES0.

FL, bit [2]

Filter by latency

0b0 Latency filtering disabled

0b1 Latency filtering enabled. Samples with a total latency less than PMSLATFR_EL1.MINLAT will not be recorded

If this field is set to 1 and PMSLATFR_EL1.MINLAT is set to zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FL is set to 0

This field resets to an architecturally UNKNOWN value.

FT, bit [1]

Filter by operation type. The filter is the logical OR of the ST, LD and B bits. For example, if LD and ST are both set, both load and store operations are recorded

0b0 Type filtering disabled

0b1 Type filtering enabled. Samples not one of the selected operation types will not be recorded

If this field is set to 1 and the PMSFCR_EL1.{ST, LD, B} bits are all set to zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FT is set to 0

This field resets to an architecturally UNKNOWN value.

FE, bit [0]

Filter by event

0b0 Event filtering disabled

0b1 Event filtering enabled. Samples not including the events selected by PMSEVFR_EL1 will not be recorded

If this field is set to 1 and PMSEVFR_EL1 is set to zero, it is CONSTRAINED UNPREDICTABLE whether no samples are recorded or the PE behaves as if PMSFCR_EL1.FE is set to 0

This field resets to an architecturally UNKNOWN value.

Accessing the PMSFCR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.6.9 PMSICR_EL1, Sampling Interval Counter Register

The PMSICR_EL1 characteristics are:

Purpose

Software must write zero to PMSICR_EL1 before enabling sample profiling for a sampling session. Software must then treat PMSICR_EL1 as an opaque, 64-bit, read/write register used for context switches only.

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSICR_EL1 are UNDEFINED.

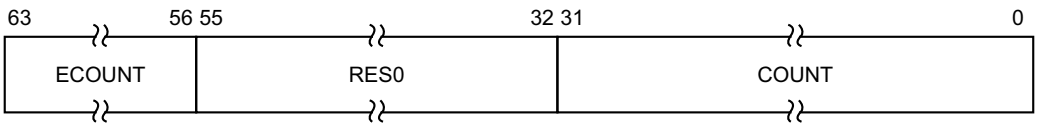
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

The value of PMSICR_EL1 does not change whilst profiling is disabled.

Field descriptions

The PMSICR_EL1 bit assignments are:



ECOUNT, bits [63:56]

When PMSIDR_EL1.ERnd == 0b1:

Secondary sample interval counter.

When PMSIDR_EL1.ERnd is 1, this field provides the secondary counter used after the primary counter reaches zero. Whilst the secondary counter is nonzero and profiling is enabled, the secondary counter decrements by 1 for each member of the sample population. The primary counter also continues to decrement since it is also nonzero. When the secondary counter reaches zero, a member of the sampling population is selected for sampling.

When PMSIDR_EL1.ERnd is 0, this field is RES1.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [55:32]

Reserved, RES0.

COUNT, bits [31:0]

Primary sample interval counter

Provides the primary counter used for sampling.

The primary counter is reloaded when the value of this register is zero and the PE moves from a state or Exception level where profiling is disabled to a state or Exception level where profiling is enabled

Whilst the primary counter is nonzero and sampling is enabled, the primary counter decrements by 1 for each member of the sample population

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the counter reaches zero, the behavior depends on the values of PMSIDR_EL1.ERnd and PMSIRR_EL1.RND

- If PMSIRR_EL1.RND == 0 or PMSIDR_EL1.ERnd == 0:
  - A member of the sampling population is selected for sampling
  - The primary counter is reloaded
- If PMSIRR_EL1.RND == 1 and PMSIDR_EL1.ERnd == 1:
  - The secondary counter is set to a random or pseudorandom value in the range `0x00` to `0xFF`
  - The primary counter is reloaded

This field resets to an architecturally UNKNOWN value.

Accessing the PMSICR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, PMSICR_EL1

D13.6.10 PMSIDR_EL1, Sampling Profiling ID Register

The PMSIDR_EL1 characteristics are:

Purpose

Describes the Statistical Profiling implementation to software

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSIDR_EL1 are UNDEFINED.

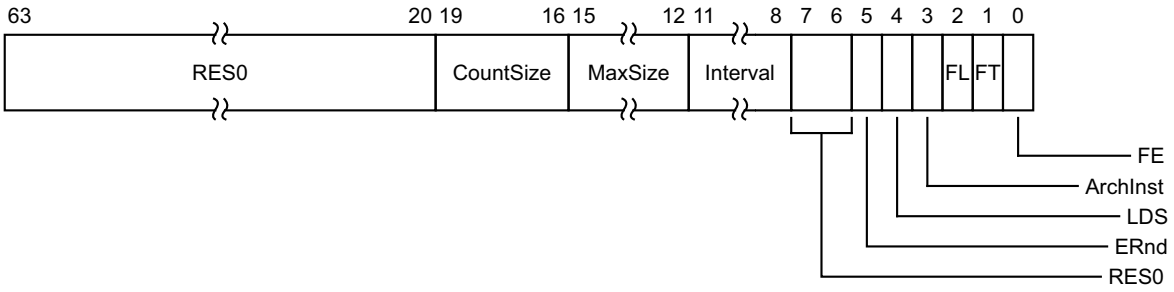
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSIDR_EL1 is a 64-bit register.

Field descriptions

The PMSIDR_EL1 bit assignments are:



Bits [63:20]

Reserved, RES0.

CountSize, bits [19:16]

Defines the size of the counters

`0b0010` 12-bit saturating counters

All other values are reserved. Reserved values might be defined in a future version of the architecture.

MaxSize, bits [15:12]

Defines the largest size for a single record, rounded up to a power-of-two. If this is the same as the minimum alignment (PMBIDR_EL1.Align), then each record is exactly this size

`0b0100` 16 bytes

`0b0101` 32 bytes

`0b0110` 64 bytes

`0b0111` 128 bytes

`0b1000` 256 bytes

`0b1001` 512 bytes

`0b1010` 1024 bytes

`0b1011` 2KB

All other values are reserved. Reserved values might be defined in a future version of the architecture.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Interval, bits [11:8]

Recommended minimum sampling interval. This provides guidance from the implementer to the smallest minimum sampling interval, N.

0b0000 256

0b0010 512

0b0011 768

0b0100 1,024

0b0101 1,536

0b0110 2,048

0b0111 3,072

0b1000 4,096

All other values are reserved. Reserved values might be defined in a future version of the architecture.

Bits [7:6]

Reserved, RES0.

ERnd, bit [5]

Defines how the random number generator is used in determining the interval between samples, when enabled by PMSIRR_EL1.RND.

0b0 The random number is added at the start of the interval, and the sample is taken and a new interval started when the combined interval expires.

0b1 The random number is added and the new interval started after the interval programmed in PMSIRR_EL1.INTERVAL expires, and the sample is taken when the random interval expires.

LDS, bit [4]

Data source indicator for sampled load instructions

0b0 Loaded data source not implemented

0b1 Loaded data source implemented

ArchInst, bit [3]

Architectural instruction profiling

0b0 Micro-op sampling implemented

0b1 Architecture instruction sampling implemented

FL, bit [2]

Filtering by latency. This bit is RAO.

FT, bit [1]

Filtering by operation type. This bit is RAO.

FE, bit [0]

Filtering by events. This bit is RAO.

Accessing the PMSIDR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.6.11 PMSIRR_EL1, Sampling Interval Reload Register

The PMSIRR_EL1 characteristics are:

Purpose

Defines the interval between samples

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSIRR_EL1 are UNDEFINED.

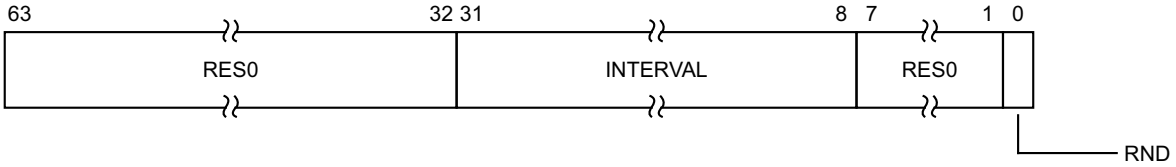
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSIRR_EL1 is a 64-bit register.

Field descriptions

The PMSIRR_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

INTERVAL, bits [31:8]

Bits [31:8] of the PMSICR_EL1 interval counter reload value. Software must set this to a non-zero value. If software sets this to zero, an UNKNOWN sampling interval is used. Software should set this to a value greater than the minimum indicated by PMSIDR_EL1.Interval

This field resets to an architecturally UNKNOWN value.

Bits [7:1]

Reserved, RES0.

RND, bit [0]

Controls randomization of the sampling interval

`0b0` Disable randomization of sampling interval

`0b1` Add (pseudo-)random jitter to sampling interval

The random number generator is not architected.

This field resets to an architecturally UNKNOWN value.

Accessing the PMSIRR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.6.12 PMSLATFR_EL1, Sampling Latency Filter Register

The PMSLATFR_EL1 characteristics are:

Purpose

Controls sample filtering by latency

Configurations

This register is present only when SPE is implemented. Otherwise, direct accesses to PMSLATFR_EL1 are UNDEFINED.

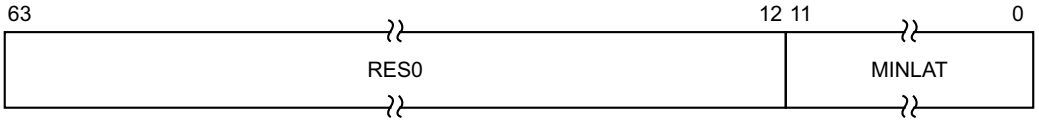
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSLATFR_EL1 is a 64-bit register.

Field descriptions

The PMSLATFR_EL1 bit assignments are:



Bits [63:12]

Reserved, RES0.

MINLAT, bits [11:0]

Minimum latency. When PMSFCR_EL1.FL == 1, defines the minimum total latency for filtered operations. Samples with a total latency less than MINLAT will not be recorded

This field is ignored by the PE when PMSFCR_EL1.FL == 0.

This field resets to an architecturally UNKNOWN value.

Accessing the PMSLATFR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.7.1 DISR_EL1, Deferred Interrupt Status Register

The DISR_EL1 characteristics are:

Purpose

Records that an SError interrupt has been consumed by an ESB instruction.

Configurations

AArch64 System register DISR_EL1[31:0] is architecturally mapped to AArch32 System register DISR[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to DISR_EL1 are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

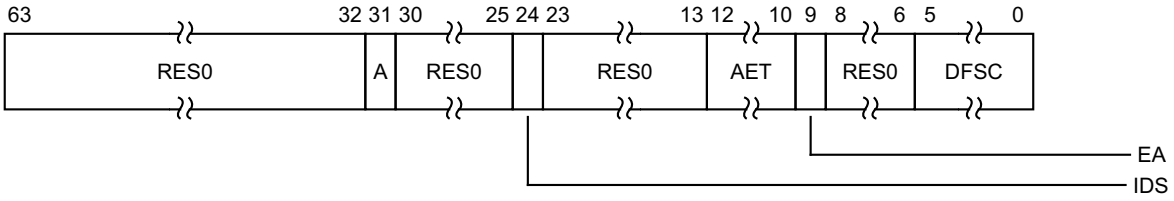
Attributes

DISR_EL1 is a 64-bit register.

Field descriptions

The DISR_EL1 bit assignments are:

When DISR_EL1.IDS == 0:



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError interrupt type.

0b0 Deferred error uses architecturally-defined format.

This field resets to an architecturally UNKNOWN value.

Bits [23:13]

Reserved, RES0.

AET, bits [12:10]

Asynchronous Error Type. See the description of ESR_ELx.AET for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EA, bit [9]

External abort Type. See the description of ESR_ELx.EA for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

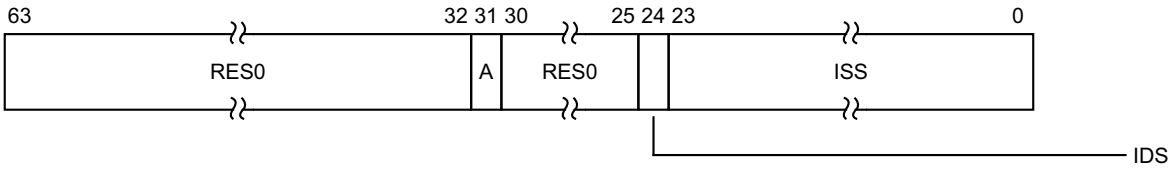
Reserved, RES0.

DFSC, bits [5:0]

Fault Status Code. See the description of ESR_ELx.DFSC for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

When DISR_EL1.IDS == 1:



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError interrupt type.

0b1 Deferred error uses IMPLEMENTATION DEFINED format.

This field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. See the description of ESR_ELx[23:0] for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

The following subsections describe each ISS format.

Accessing the DISR_EL1

An indirect write to DISR_EL1 made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR_EL1 occurring in program order after the ESB instruction.

DISR_EL1 is RAZ/WI if EL3 is implemented, the PE is in Non-debug state, SCR_EL3.EA == 1, and any of the following apply:

- At EL2.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- At EL1 and ((SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0) || HCR_EL2.AMO == 0).

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, DISR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1100	0b0001	0b001

D13.7.2 ERRIDR_EL1, Error Record ID Register

The ERRIDR_EL1 characteristics are:

Purpose

Defines the highest numbered index of the error records that can be accessed through the Error Record System registers.

Configurations

AArch64 System register ERRIDR_EL1[31:0] is architecturally mapped to AArch32 System register ERRIDR[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRIDR_EL1 are UNDEFINED.

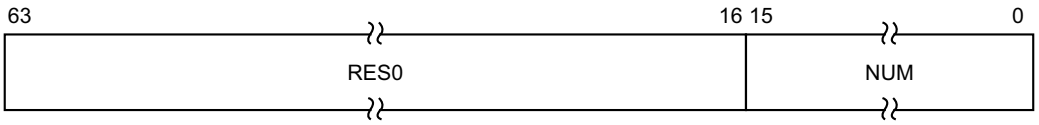
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERRIDR_EL1 is a 64-bit register.

Field descriptions

The ERRIDR_EL1 bit assignments are:



Bits [63:16]

Reserved, RES0.

NUM, bits [15:0]

Highest numbered index of the records that can be accessed through the Error Record System registers plus one. Zero indicates that no records can be accessed through the Error Record System registers.

Each implemented record is owned by a node. A node might own multiple records.

Accessing the ERRIDR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, ERRIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0011	0b000

```

D13.7.3 ERRSELR_EL1, Error Record Select Register

The ERRSELR_EL1 characteristics are:

Purpose

Selects an error record to be accessed through the Error Record System registers.

Configurations

AArch64 System register ERRSELR_EL1[31:0] is architecturally mapped to AArch32 System register ERRSELR[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRSELR_EL1 are UNDEFINED.

If ERRIDR_EL1 indicates that zero records are implemented, then it is IMPLEMENTATION DEFINED whether ERRSELR_EL1 is UNDEFINED or RES0.

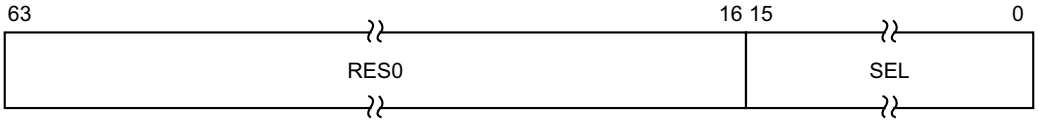
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERRSELR_EL1 is a 64-bit register.

Field descriptions

The ERRSELR_EL1 bit assignments are:



Bits [63:16]

Reserved, RES0.

SEL, bits [15:0]

Selects the record accessed through the ERX registers.

For example, if ERRSELR_EL1.SEL is set to `0x4`, then direct reads and writes of ERXSTATUS_EL1 access ERR4STATUS.

If ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then all of the following apply:

- The value read back from ERRSELR_EL1.SEL is UNKNOWN.
- One of the following occurs:
  - An UNKNOWN error record is selected.
  - The ERX* registers are RAZ/WI.
  - ERX* register reads and writes are NOPs.
  - ERX* register reads and writes are UNDEFINED.

This field resets to an architecturally UNKNOWN value.

Accessing the ERRSELR_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

D13.7.4 ERXADDR_EL1, Selected Error Record Address Register

The ERXADDR_EL1 characteristics are:

Purpose

Accesses ERR<n>ADDR for the error record selected by ERRSELR_EL1.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch64 System register ERXADDR_EL1[31:0] is architecturally mapped to AArch32 System register ERXADDR[31:0].

AArch64 System register ERXADDR_EL1[63:32] is architecturally mapped to AArch32 System register ERXADDR2[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXADDR_EL1 are UNDEFINED.

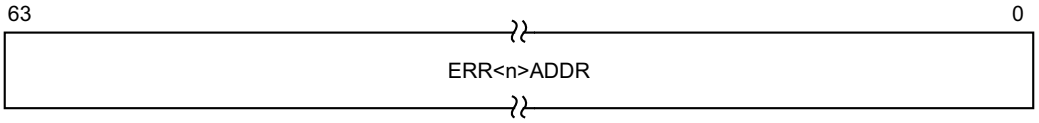
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXADDR_EL1 is a 64-bit register.

Field descriptions

The ERXADDR_EL1 bit assignments are:



Bits [63:0]

ERXADDR_EL1 accesses ERR<n>ADDR, where n is the value in ERRSELR_EL1.SEL.

Accessing the ERXADDR_EL1

If ERRIDR_EL1.NUM == 0 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXADDR_EL1 is RAZ/WI.
- Direct reads and writes of ERXADDR_EL1 are NOPs.
- Direct reads and writes of ERXADDR_EL1 are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.7.5 ERXCTLR_EL1, Selected Error Record Control Register

The ERXCTLR_EL1 characteristics are:

Purpose

Accesses ERR<n>CTLR for the error record selected by ERRSELR_EL1.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch64 System register ERXCTLR_EL1[31:0] is architecturally mapped to AArch32 System register ERXCTLR[31:0].

AArch64 System register ERXCTLR_EL1[63:32] is architecturally mapped to AArch32 System register ERXCTLR2[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXCTLR_EL1 are UNDEFINED.

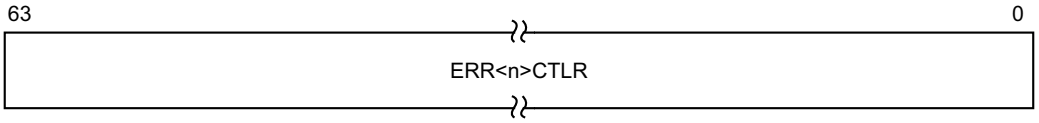
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXCTLR_EL1 is a 64-bit register.

Field descriptions

The ERXCTLR_EL1 bit assignments are:



Bits [63:0]

ERXCTLR_EL1 accesses ERR<n>CTLR, where n is the value in ERRSELR_EL1.SEL.

Accessing the ERXCTLR_EL1

If ERRIDR_EL1.NUM == 0 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXCTLR_EL1 is RAZ/WI.
- Direct reads and writes of ERXCTLR_EL1 are NOPs.
- Direct reads and writes of ERXCTLR_EL1 are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, ERXCTLR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b001

D13.7.6 ERXFR_EL1, Selected Error Record Feature Register

The ERXFR_EL1 characteristics are:

Purpose

Accesses ERR<n>FR for the error record selected by ERRSELR_EL1.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch64 System register ERXFR_EL1[31:0] is architecturally mapped to AArch32 System register ERXFR[31:0].

AArch64 System register ERXFR_EL1[63:32] is architecturally mapped to AArch32 System register ERXFR2[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXFR_EL1 are UNDEFINED.

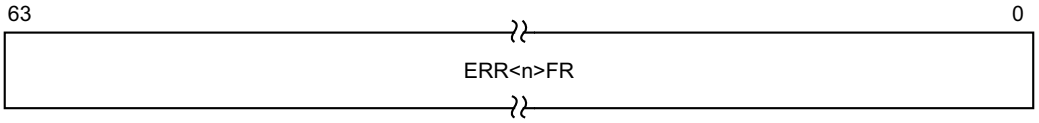
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXFR_EL1 is a 64-bit register.

Field descriptions

The ERXFR_EL1 bit assignments are:



Bits [63:0]

ERXFR_EL1 accesses ERR<n>FR, where n is the value in ERRSELR_EL1.SEL.

Accessing the ERXFR_EL1

If ERRIDR_EL1.NUM == 0 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXFR_EL1 is RAZ.
- Direct reads of ERXFR_EL1 are NOPs.
- Direct reads of ERXFR_EL1 are UNDEFINED.

D13.7.7 ERXMISC0_EL1, Selected Error Record Miscellaneous Register 0

The ERXMISC0_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC0 for the error record selected by ERRSELR_EL1.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch64 System register ERXMISC0_EL1[31:0] is architecturally mapped to AArch32 System register ERXMISC0[31:0].

AArch64 System register ERXMISC0_EL1[63:32] is architecturally mapped to AArch32 System register ERXMISC1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXMISC0_EL1 are UNDEFINED.

For IMPLEMENTATION DEFINED fields in this register, writing zero must always be supported to return the error record to an initial state.

In particular, if any IMPLEMENTATION DEFINED syndrome fields might generate a Fault Handling or Error Recovery Interrupt request, writing zero is sufficient to deactivate the Interrupt request.

Fields that are read-only, non-zero and ignore writes are compliant with this requirement.

Note

Arm recommends that any IMPLEMENTATION DEFINED syndrome fields that can generate a Fault Handling, Error Recovery, Critical, or IMPLEMENTATION DEFINED, interrupt request are disabled at Cold reset and are enabled by software writing an IMPLEMENTATION DEFINED non-zero value to an IMPLEMENTATION DEFINED field in ERR<q>CTRL, where q is the index of the first error record owned by the same node as error record n. If the node owns a single record then q = n.

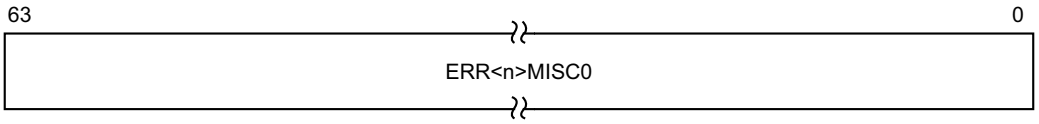
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXMISC0_EL1 is a 64-bit register.

Field descriptions

The ERXMISC0_EL1 bit assignments are:



Bits [63:0]

ERXMISC0_EL1 accesses ERR<n>MISC0, where n is the value in ERRSELR_EL1.SEL.

Accessing the ERXMISC0_EL1

If ERRIDR_EL1.NUM == 0 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXMISC0_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC0_EL1 are NOPs.

D13.7.11 ERXPFGCDN_EL1, Selected Pseudo-fault Generation Countdown Register

The ERXPFGCDN_EL1 characteristics are:

Purpose

Accesses the ERR<n>PFGCDN register for the error record selected by ERRSELR_EL1.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERXPFGCDN_EL1 are UNDEFINED.

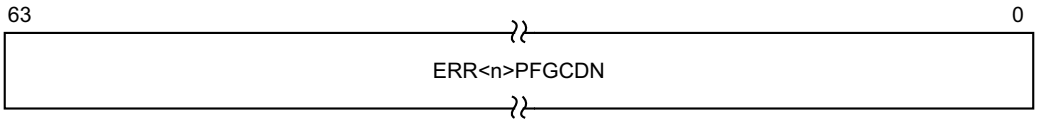
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXPFGCDN_EL1 is a 64-bit register.

Field descriptions

The ERXPFGCDN_EL1 bit assignments are:



Bits [63:0]

ERXPFGCDN_EL1 accesses ERR<n>PFGCDN, where n is the value in ERRSELR_EL1.SEL.

Accessing the ERXPFGCDN_EL1

If ERRIDR_EL1.NUM == 0 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record that does not implement the RAS Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

Note

An error record does not implement the RAS Common Fault Injection Model Extension when ERR<n>FR.INJ == `0b00`.

D13.7.14 ERXSTATUS_EL1, Selected Error Record Primary Status Register

The ERXSTATUS_EL1 characteristics are:

Purpose

Accesses ERR<n>STATUS for the error record selected by ERRSELR_EL1.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch64 System register ERXSTATUS_EL1[31:0] is architecturally mapped to AArch32 System register ERXSTATUS[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXSTATUS_EL1 are UNDEFINED.

For IMPLEMENTATION DEFINED fields in this register, writing zero must always be supported to return the error record to an initial state.

In particular, if any IMPLEMENTATION DEFINED syndrome fields might generate a Fault Handling or Error Recovery Interrupt request, writing zero is sufficient to deactivate the Interrupt request.

Fields that are read-only, non-zero and ignore writes are compliant with this requirement.

Note

Arm recommends that any IMPLEMENTATION DEFINED syndrome fields that can generate a Fault Handling, Error Recovery, Critical, or IMPLEMENTATION DEFINED, interrupt request are disabled at Cold reset and are enabled by software writing an IMPLEMENTATION DEFINED non-zero value to an IMPLEMENTATION DEFINED field in ERR<q>CTRL, where q is the index of the first error record owned by the same node as error record n. If the node owns a single record then q = n.

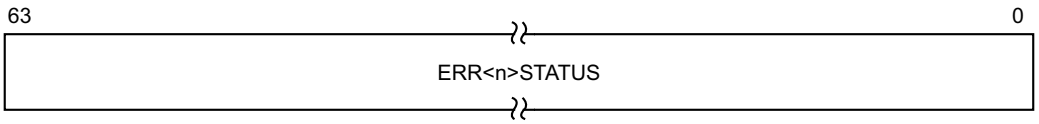
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXSTATUS_EL1 is a 64-bit register.

Field descriptions

The ERXSTATUS_EL1 bit assignments are:



Bits [63:0]

ERXSTATUS_EL1 accesses ERR<n>STATUS, where n is the value in ERRSELR_EL1.SEL.

Accessing the ERXSTATUS_EL1

If ERRIDR_EL1.NUM == 0 or ERRSELR_EL1.SEL is set to a value greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXSTATUS_EL1 is RAZ/WI.
- Direct reads and writes of ERXSTATUS_EL1 are NOPs.
- Direct reads and writes of ERXSTATUS_EL1 are UNDEFINED.

D13.7.15 VDISR_EL2, Virtual Deferred Interrupt Status Register

The VDISR_EL2 characteristics are:

Purpose

Records that a virtual SError interrupt has been consumed by an ESB instruction executed at EL1.

An indirect write to VDISR_EL2 made by an ESB instruction does not require an explicit synchronization operation for the value written to be observed by a direct read of DISR_EL1 or DISR occurring in program order after the ESB instruction.

Configurations

AArch64 System register VDISR_EL2[31:0] is architecturally mapped to AArch32 System register VDISR[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to VDISR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

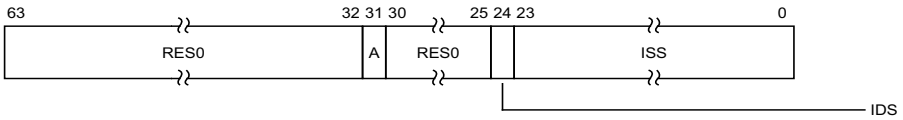
Attributes

VDISR_EL2 is a 64-bit register.

Field descriptions

The VDISR_EL2 bit assignments are:

When !ELUsingAArch32(EL1):



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers a virtual SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

The value copied from VSESR_EL2.IDS.

This field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

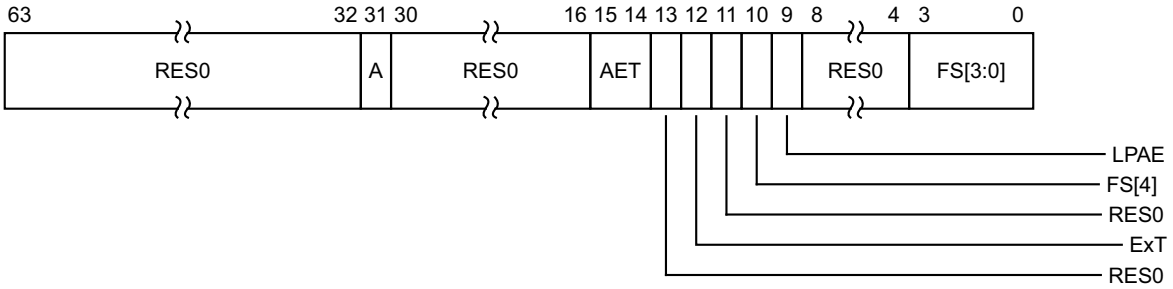
The value copied from VSESR_EL2.ISS.

This field resets to an architecturally UNKNOWN value.

The following subsections describe each ISS format.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When ELUsingAArch32(EL1) and VDISR_EL2.LPAE == 0:



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers a virtual SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

The value copied from VSESR_EL2.AET.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

The value copied from VSESR_EL2.ExT.

This field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES0.

FS[4], bit [10]

This field is bit[4] of FS[4:0].

Fault status code. Set to 0b10110 when an ESB instruction defers a virtual SError interrupt.

0b10110 Asynchronous SError interrupt.

All other values are reserved.

The FS field is split as follows:

- FS[4] is VDISR_EL2[10].
- FS[3:0] is VDISR_EL2[3:0].

This field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

Format.

Set to TTBCR.EAE when an ESB instruction defers a virtual SError interrupt.

0b0 Using the Short-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [8:4]

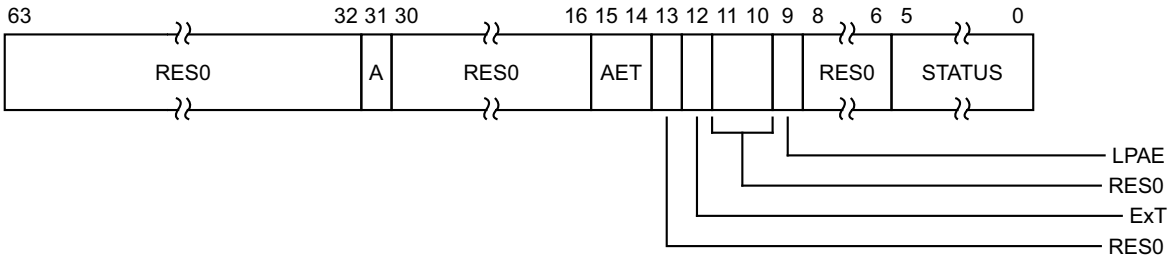
Reserved, RES0.

FS[3:0], bits [3:0]

This field is bits[3:0] of FS[4:0].

See FS[4] for the field description.

When ELUsingAArch32(EL1) and VDISR_EL2.LPAE == 1:



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers a virtual SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

The value copied from VSESR_EL2.AET.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

The value copied from VSESR_EL2.ExT.

This field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

Format.

Set to TTBCR.EAE when an ESB instruction defers a virtual SError interrupt.

0b1 Using the Long-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

STATUS, bits [5:0]

Fault status code. Set to `0b010001` when an `ESB` instruction defers a virtual SError interrupt.

`0b010001` Asynchronous SError interrupt.

All other values are reserved.

This field resets to an architecturally UNKNOWN value.

Accessing the VDISR_EL2

An indirect write to VDISR_EL2 made by an `ESB` instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR_EL1 or DISR occurring in program order after the `ESB` instruction.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.7.16 VSESR_EL2, Virtual SError Exception Syndrome Register

The VSESR_EL2 characteristics are:

Purpose

Provides the syndrome value reported to software on taking a virtual SError interrupt exception to EL1, or on executing an ESB instruction at EL1.

When the virtual SError interrupt is taken to EL1 using AArch64, then the syndrome value is reported in ESR_EL1.

When the virtual SError interrupt is taken to EL1 using AArch32, then the syndrome value is reported in DFSR.{AET, ExT} and the remainder of DFSR is set as defined by VMSAv8-32. For more information, see Chapter G5 *The AArch32 Virtual Memory System Architecture*.

When the virtual SError interrupt is deferred by an ESB instruction, then the syndrome value is written to VDISR_EL2.

Configurations

AArch64 System register VSESR_EL2[31:0] is architecturally mapped to AArch32 System register VDFSR[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to VSESR_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

RW fields in this register reset to architecturally UNKNOWN values.

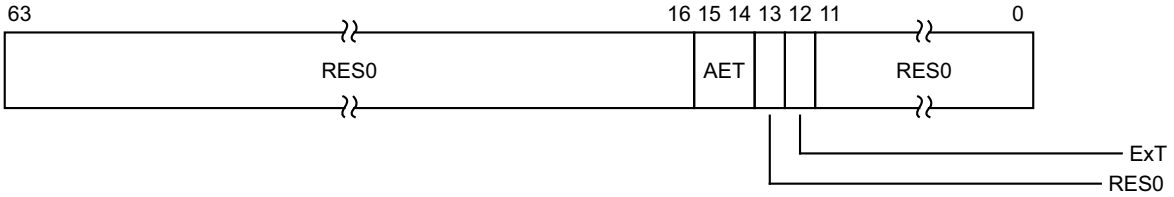
Attributes

VSESR_EL2 is a 64-bit register.

Field descriptions

The VSESR_EL2 bit assignments are:

When ELUsingAArch32(EL1):



Bits [63:16]

Reserved, RES0.

AET, bits [15:14]

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[15:4] is set to VSESR_EL2.AET.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR_EL2[15:4] is set to VSESR_EL2.AET.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

Bits [63:25]

Reserved, RES0.

IDS, bit [24]

When a virtual SError interrupt is taken to EL1 using AArch64, ESR_EL1[24] is set to VSESR_EL2.IDS.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR_EL2[24] is set to VSESR_EL2.IDS.

This field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

When a virtual SError interrupt is taken to EL1 using AArch64, ESR_EL1[23:0] is set to VSESR_EL2.ISS.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR_EL2[23:0] is set to VSESR_EL2.ISS.

This field resets to an architecturally UNKNOWN value.

The following subsections describe each ISS format.

Accessing the VSESR_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, VSESR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b011

```
if PSTATE.EL == EL0 then

D13.8 Generic Timer registers

This section lists the Generic Timer registers in AArch64.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D13.8.1 CNTFRQ_EL0, Counter-timer Frequency register

The CNTFRQ_EL0 characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Configurations

AArch64 System register CNTFRQ_EL0[31:0] is architecturally mapped to AArch32 System register CNTFRQ[31:0].

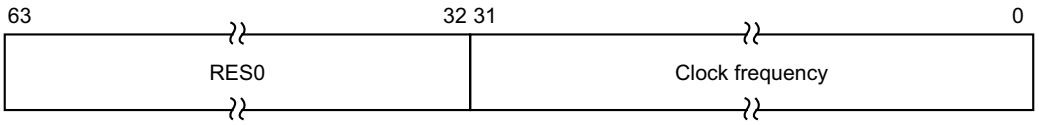
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTFRQ_EL0 is a 64-bit register.

Field descriptions

The CNTFRQ_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTFRQ_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTFRQ_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    if !ELUsingAArch32(EL1) && !(EL2Enabled() && HCR_EL2.<E2H,TGE> == '11') &&
CNTKCTL_EL1.<EL0PCTEN,EL0VCTEN> == '00' then
        if EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    elsif EL2Enabled() && !ELUsingAArch32(EL2) && HCR_EL2.<E2H,TGE> == '11' &&

D13.8.2 CNTHCTL_EL2, Counter-timer Hypervisor Control register

The CNTHCTL_EL2 characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from EL1 to the physical counter and the EL1 physical timer.

Configurations

AArch64 System register CNTHCTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHCTL[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

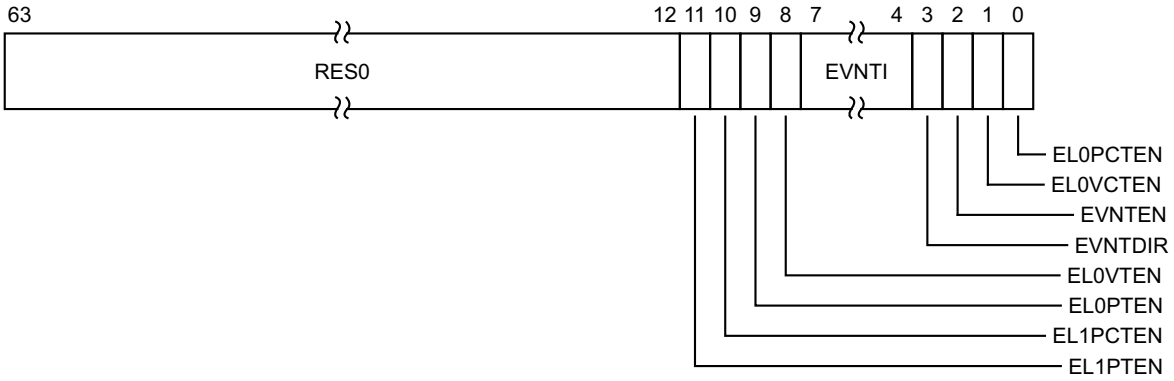
Attributes

CNTHCTL_EL2 is a 64-bit register.

Field descriptions

The CNTHCTL_EL2 bit assignments are:

When ARMv8.1-VHE is implemented and HCR_EL2.E2H == 1:



Bits [63:12]

Reserved, RES0.

EL1PTEN, bit [11]

When HCR_EL2.TGE is 0, traps EL0 and EL1 accesses to the E1 physical timer registers to EL2 when EL2 is enabled in the current Security state.

`0b0` From AArch64 state: EL0 and EL1 accesses to the CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN.

From AArch32 state: EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN or CNTKCTL.PL0PTEN.

`0b1` This control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL1PCTEN, bit [10]

When HCR_EL2.TGE is 0, traps EL0 and EL1 accesses to the EL1 physical counter register to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTPCT_EL0 are trapped to EL2, reported using EC syndrome value `0x18`.
- In AArch32 state, MRRC or MCRR accesses to CNTPCT are trapped to EL2, reported using EC syndrome value `0x04`.

`0b0` From AArch64 state: EL0 and EL1 accesses to the CNTPCT_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN.

From AArch32 state: EL0 and EL1 accesses to the CNTPCT are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN or CNTKCTL.PL0PCTEN.

`0b1` This control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL0PTEN, bit [9]

When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, traps EL0 accesses to the physical timer registers to EL2.

`0b0` EL0 using AArch64: EL0 accesses to the CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0 registers are trapped to EL2.

EL0 using AArch32: EL0 accesses to the CNTP_CTL, CNTP_CVAL and CNTP_TVAL registers are trapped to EL2.

`0b1` This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL0VTEN, bit [8]

When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, traps EL0 accesses to the virtual timer registers to EL2.

`0b0` EL0 using AArch64: EL0 accesses to the CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0 registers are trapped to EL2.

EL0 using AArch32: EL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are trapped to EL2.

`0b1` This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register CNTPCT_EL0 is the trigger for the event stream generated from that counter, when that stream is enabled.

This field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the counter register CNTPCT_EL0 trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

`0b0` A 0 to 1 transition of the trigger bit triggers an event.

`0b1` A 1 to 0 transition of the trigger bit triggers an event.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register CNTPCT_EL0:

0b0 Disables the event stream.

0b1 Enables the event stream.

This field resets to an architecturally UNKNOWN value.

EL0VCTEN, bit [1]

When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, traps EL0 accesses to the frequency register and virtual counter register to EL2.

0b0 EL0 using AArch64: EL0 accesses to the CNTVCT_EL0 are trapped to EL2.

EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL2, if CNTHCTL_EL2.EL0PCTEN is also 0.

EL0 using AArch32: EL0 accesses to the CNTVCT are trapped to EL2.

EL0 using AArch32: EL0 accesses to the CNTFRQ register are trapped to EL2, if CNTHCTL.EL0PCTEN is also 0.

0b1 This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL0PCTEN, bit [0]

When HCR_EL2.TGE is 0, this control does not cause any instructions to be trapped.

When HCR_EL2.TGE is 1, traps EL0 accesses to the frequency register and physical counter register to EL2.

0b0 EL0 using AArch64: EL0 accesses to the CNTPCT_EL0 are trapped to EL2.

EL0 using AArch64: EL0 accesses to the CNTFRQ_EL0 register are trapped to EL2, if CNTHCTL_EL2.EL0VCTEN is also 0.

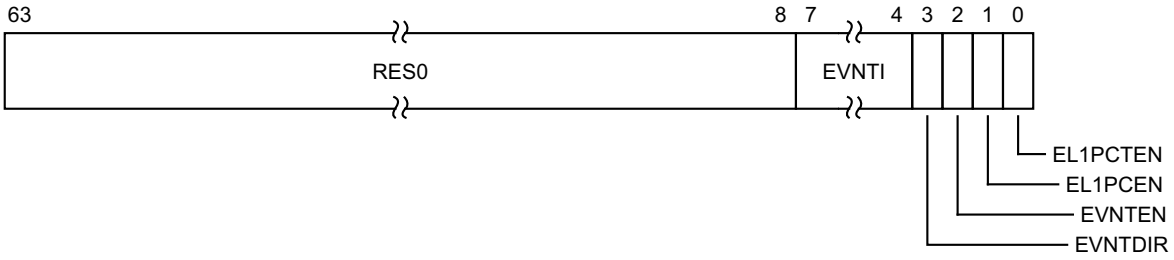
EL0 using AArch32: EL0 accesses to the CNTPCT are trapped to EL2.

EL0 using AArch32: EL0 accesses to the CNTFRQ and register are trapped to EL2, if CNTHCTL_EL2.EL0VCTEN is also 0.

0b1 This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

Otherwise:



This format applies in all Armv8.0 implementations, and it also contains a description of the behavior when EL3 is implemented and EL2 is not implemented.

Bits [63:8]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register CNTPCT_EL0 is the trigger for the event stream generated from that counter, when that stream is enabled.

This field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the counter register CNTPCT_EL0 trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

`0b0` A 0 to 1 transition of the trigger bit triggers an event.

`0b1` A 1 to 0 transition of the trigger bit triggers an event.

This field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register CNTPCT_EL0:

`0b0` Disables the event stream.

`0b1` Enables the event stream.

This field resets to `0`.

EL1PCEN, bit [1]

Traps EL0 and EL1 accesses to the EL1 physical timer registers to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTP_CTL_EL0, CNTP_CVAL_EL0, CNTP_TVAL_EL0 are trapped to EL2, reported using EC syndrome value `0x18`.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 reported using EC syndrome value `0x3` and MRRC and MCRR accesses are trapped to EL2, reported using EC syndrome value `0x04`:
  - CNTP_CTL, CNTP_CVAL, CNTP_TVAL.

`0b0` From AArch64 state: EL0 and EL1 accesses to the CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN.

From AArch32 state: EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PTEN or CNTKCTL.PL0PTEN.

`0b1` This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.

EL1PCTEN, bit [0]

Traps EL0 and EL1 accesses to the EL1 physical counter register to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTPCT_EL0 are trapped to EL2, reported using EC syndrome value `0x18`.
- In AArch32 state, MRRC or MCRR accesses to CNTPCT are trapped to EL2, reported using EC syndrome value `0x04`.

`0b0` From AArch64 state: EL0 and EL1 accesses to the CNTPCT_EL0 are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN.

From AArch32 state: EL0 and EL1 accesses to the CNTPCT are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by CNTKCTL_EL1.EL0PCTEN or CNTKCTL.PL0PCTEN.

`0b1` This control does not cause any instructions to be trapped.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHCTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHCTL_EL2 or CNTKCTL_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTHCTL_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0001	0b000

D13.8.3 CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register

The CNTHP_CTL_EL2 characteristics are:

Purpose

Control register for the EL2 physical timer.

Configurations

AArch64 System register CNTHP_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHP_CTL[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

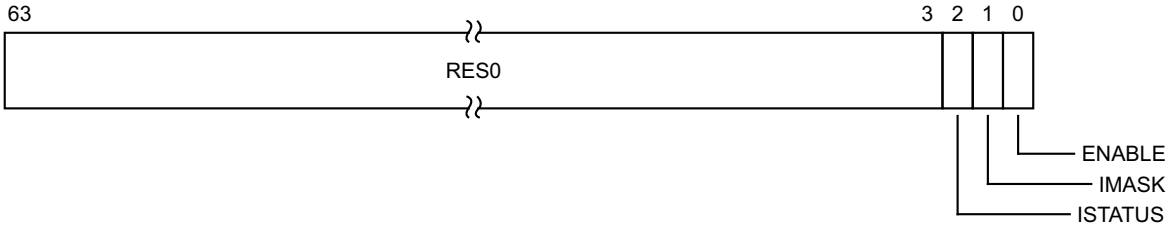
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CTL_EL2 is a 64-bit register.

Field descriptions

The CNTHP_CTL_EL2 bit assignments are:



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHP_TVAL_EL2 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHP_CTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_CTL_EL2 or CNTP_CTL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.4 CNTHP_CVAL_EL2, Counter-timer Physical Timer CompareValue register (EL2)

The CNTHP_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the EL2 physical timer.

Configurations

AArch64 System register CNTHP_CVAL_EL2[63:0] is architecturally mapped to AArch32 System register CNTHP_CVAL[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

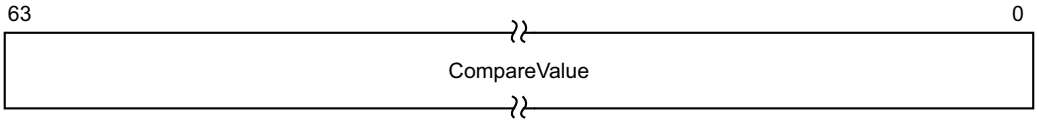
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHP_CVAL_EL2 bit assignments are:



CompareValue, bits [63:0]

Holds the EL2 physical timer CompareValue.

When CNTHP_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHP_CTL_EL2.ISTATUS is set to 1.
- If CNTHP_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHP_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHP_CVAL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_CVAL_EL2 or CNTP_CVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.5 CNTHP_TVAL_EL2, Counter-timer Physical Timer TimerValue register (EL2)

The CNTHP_TVAL_EL2 characteristics are:

Purpose

Holds the timer value for the EL2 physical timer.

Configurations

AArch64 System register CNTHP_TVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHP_TVAL[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

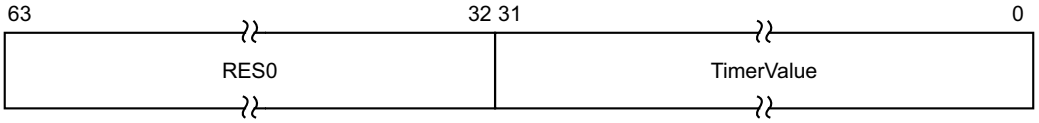
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_TVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHP_TVAL_EL2 bit assignments are:



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHP_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHP_CTL_EL2.ENABLE is 1, the value returned is (CNTHP_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHP_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHP_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHP_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHP_CTL_EL2.ISTATUS is set to 1.
- If CNTHP_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHP_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHP_TVAL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHP_TVAL_EL2 or CNTP_TVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.6 CNTHPS_CTL_EL2, Counter-timer Secure Physical Timer Control register (EL2)

The CNTHPS_CTL_EL2 characteristics are:

Purpose

Control register for the Secure EL2 physical timer.

Configurations

AArch64 System register CNTHPS_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHPS_CTL[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_CTL_EL2 are UNDEFINED.

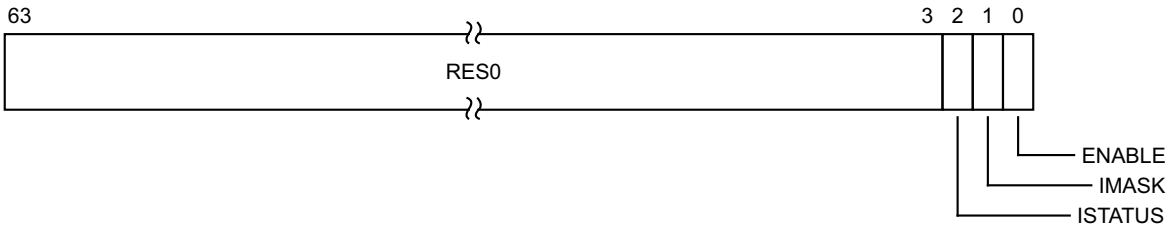
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHPS_CTL_EL2 is a 64-bit register.

Field descriptions

The CNTHPS_CTL_EL2 bit assignments are:



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

0b0 Timer condition is not met.

0b1 Timer condition is met.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0b0 Timer interrupt is not masked by the IMASK bit.

0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHPS_TVAL_EL2 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

D13.8.7 CNTHPS_CVAL_EL2, Counter-timer Secure Physical Timer CompareValue register (EL2)

The CNTHPS_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the Secure EL2 physical timer.

Configurations

AArch64 System register CNTHPS_CVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHPS_CVAL[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_CVAL_EL2 are UNDEFINED.

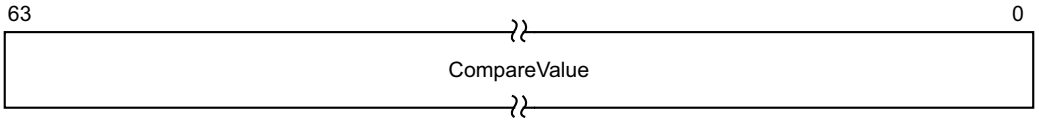
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHPS_CVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHPS_CVAL_EL2 bit assignments are:



CompareValue, bits [63:0]

Holds the EL2 physical timer CompareValue.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHPS_CVAL_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.8 CNTHPS_TVAL_EL2, Counter-timer Secure Physical Timer TimerValue register (EL2)

The CNTHPS_TVAL_EL2 characteristics are:

Purpose

Holds the timer value for the Secure EL2 physical timer.

Configurations

AArch64 System register CNTHPS_TVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHPS_TVAL[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_TVAL_EL2 are UNDEFINED.

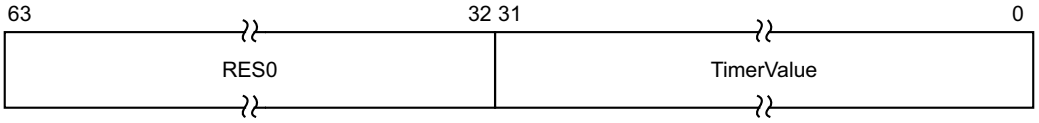
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHPS_TVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHPS_TVAL_EL2 bit assignments are:



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHPS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHPS_CTL_EL2.ENABLE is 1, the value returned is (CNTHPS_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHPS_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHPS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHPS_TVAL_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.9 CNTHV_CTL_EL2, Counter-timer Virtual Timer Control register (EL2)

The CNTHV_CTL_EL2 characteristics are:

Purpose

Control register for the EL2 virtual timer.

Configurations

AArch64 System register CNTHV_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHV_CTL[31:0].

This register is present only when ARMv8.1-VHE is implemented. Otherwise, direct accesses to CNTHV_CTL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

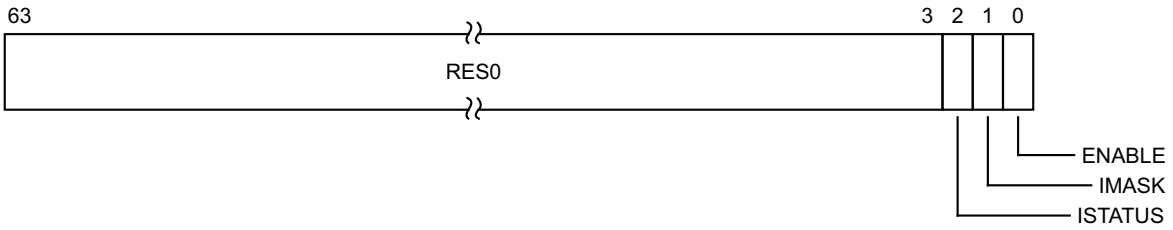
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHV_CTL_EL2 is a 64-bit register.

Field descriptions

The CNTHV_CTL_EL2 bit assignments are:



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHV_TVAL_EL2 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHV_CTL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_CTL_EL2 or CNTV_CTL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTHV_CTL_EL2

D13.8.10 CNTHV_CVAL_EL2, Counter-timer Virtual Timer CompareValue register (EL2)

The CNTHV_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the EL2 virtual timer.

Configurations

AArch64 System register CNTHV_CVAL_EL2[63:0] is architecturally mapped to AArch32 System register CNTHV_CVAL[63:0].

This register is present only when ARMv8.1-VHE is implemented. Otherwise, direct accesses to CNTHV_CVAL_EL2 are UNDEFINED.

If EL2 is not implemented, this register is RES0 from EL3.

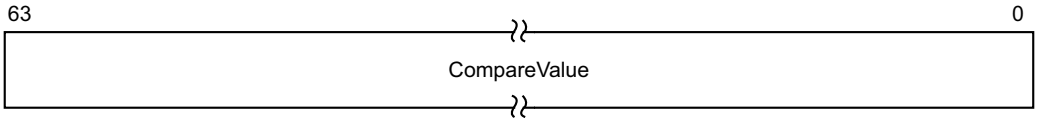
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHV_CVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHV_CVAL_EL2 bit assignments are:



CompareValue, bits [63:0]

Holds the EL2 virtual timer CompareValue.

When CNTHV_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHV_CTL_EL2.ISTATUS is set to 1.
- If CNTHV_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHV_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHV_CVAL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_CVAL_EL2 or CNTV_CVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

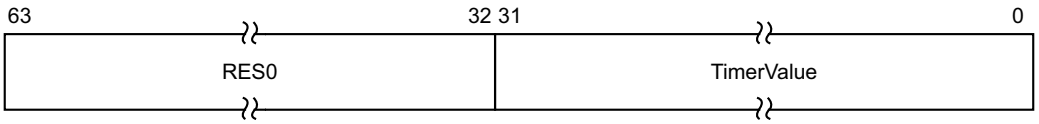
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHV_TVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHV_TVAL_EL2 bit assignments are:



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHV_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHV_CTL_EL2.ENABLE is 1, the value returned is (CNTHV_CVAL_EL2 - CNTVCT_EL0).

On a write of this register, CNTHV_CVAL_EL2 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHV_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CNTHV_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHV_CTL_EL2.ISTATUS is set to 1.
- If CNTHV_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHV_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHV_TVAL_EL2

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic CNTHV_TVAL_EL2 or CNTV_TVAL_EL0 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

D13.8.12 CNTHVS_CTL_EL2, Counter-timer Secure Virtual Timer Control register (EL2)

The CNTHVS_CTL_EL2 characteristics are:

Purpose

Control register for the Secure EL2 virtual timer.

Configurations

AArch64 System register CNTHVS_CTL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHVS_CTL[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_CTL_EL2 are UNDEFINED.

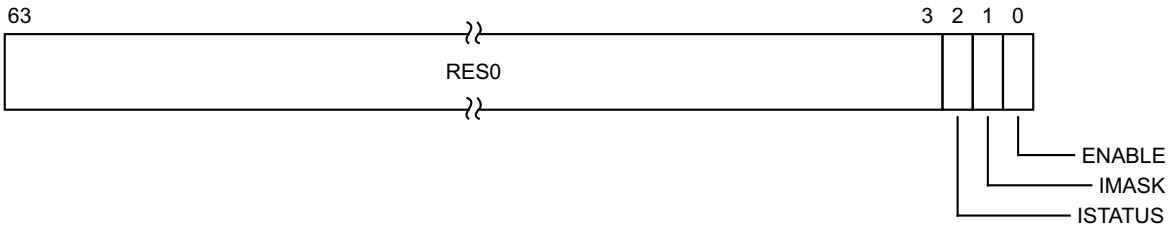
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHVS_CTL_EL2 is a 64-bit register.

Field descriptions

The CNTHVS_CTL_EL2 bit assignments are:



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the CNTHVS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the CNTHVS_CTL_EL2.ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHVS_TVAL_EL2 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

D13.8.13 CNTHVS_CVAL_EL2, Counter-timer Secure Virtual Timer CompareValue register (EL2)

The CNTHVS_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the Secure EL2 virtual timer.

Configurations

AArch64 System register CNTHVS_CVAL_EL2[63:0] is architecturally mapped to AArch32 System register CNTHVS_CVAL[63:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_CVAL_EL2 are UNDEFINED.

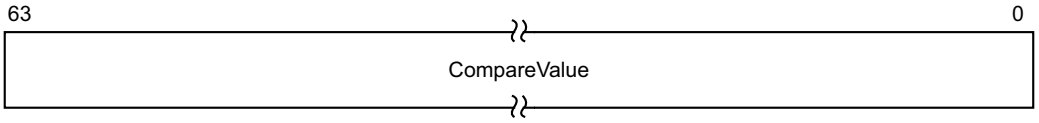
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHVS_CVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHVS_CVAL_EL2 bit assignments are:



CompareValue, bits [63:0]

Holds the Secure EL2 virtual timer CompareValue.

When CNTHVS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHVS_CTL_EL2.ISTATUS is set to 1.
- If CNTHVS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

D13.8.14 CNTHVS_TVAL_EL2, Counter-timer Secure Virtual Timer TimerValue register (EL2)

The CNTHVS_TVAL_EL2 characteristics are:

Purpose

Holds the timer value for the Secure EL2 virtual timer.

Configurations

AArch64 System register CNTHVS_TVAL_EL2[31:0] is architecturally mapped to AArch32 System register CNTHVS_TVAL[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_TVAL_EL2 are UNDEFINED.

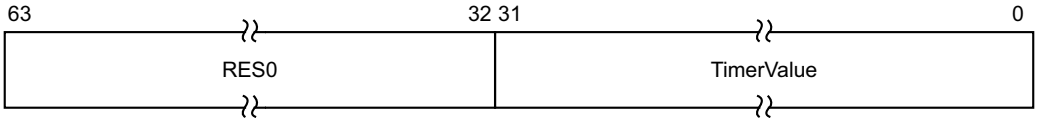
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHVS_TVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHVS_TVAL_EL2 bit assignments are:



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHVS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHVS_CTL_EL2.ENABLE is 1, the value returned is (CNTHVS_CVAL_EL2 - CNTVCT_EL0).

On a write of this register, CNTHVS_CVAL_EL2 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHVS_CTL_EL2.ENABLE is 1, the timer condition is met when ((CNTVCT_EL0 - CNTHVS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHVS_CTL_EL2.ISTATUS is set to 1.
- If CNTHVS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHVS_TVAL_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.15 CNTKCTL_EL1, Counter-timer Kernel Control register

The CNTKCTL_EL1 characteristics are:

Purpose

When ARMv8.1-VHE is not implemented, or when HCR_EL2.{E2H, TGE} is not {1, 1}, this register controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

When ARMv8.1-VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this register does not cause any event stream from the virtual counter to be generated, and does not control access to the counters and timers. The access to counters and timers at EL0 is controlled by CNTHCTL_EL2.

Configurations

AArch64 System register CNTKCTL_EL1[31:0] is architecturally mapped to AArch32 System register CNTKCTL[31:0].

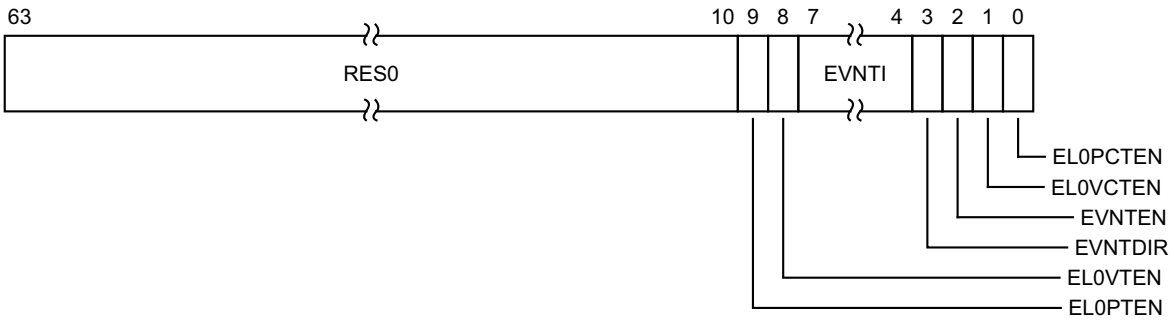
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTKCTL_EL1 is a 64-bit register.

Field descriptions

The CNTKCTL_EL1 bit assignments are:



Bits [63:10]

Reserved, RES0.

EL0PTEN, bit [9]

Traps EL0 accesses to the physical timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, the following registers are trapped, reported using EC syndrome value `0x18`:
  - CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0.
- In AArch32 state, MRC and MCR accesses to the following registers are trapped, reported using EC syndrome value `0x03`, MRRC and MCRR accesses are trapped, reported using EC syndrome value `0x04`:
  - CNTP_CTL, CNTP_CVAL, CNTP_TVAL.

`0b0` EL0 accesses to the physical timer registers are trapped to EL1.

`0b1` This control does not cause any instructions to be trapped.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When ARMv8.1-VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL0VTEN, bit [8]

Traps EL0 accesses to the virtual timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped, reported using EC syndrome value `0x18`:
  - CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0.
- In AArch32 state, MRC and MCR accesses to the following registers are trapped and reported using EC syndrome value `0x03`, MRRC and MCRR accesses are trapped using EC syndrome value `0x04`:
  - CNTV_CTL, CNTV_CVAL, and CNTV_TVAL.

`0b0` EL0 accesses to the virtual timer registers are trapped.

`0b1` This control does not cause any instructions to be trapped.

When ARMv8.1-VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register CNTVCT_EL0 is the trigger for the event stream generated from that counter, when that stream is enabled.

This field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the counter register CNTVCT_EL0 trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

`0b0` A 0 to 1 transition of the trigger bit triggers an event.

`0b1` A 1 to 0 transition of the trigger bit triggers an event.

This field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]

When ARMv8.1-VHE is not implemented, or when HCR_EL2.{E2H, TGE} is not {1, 1}, enables the generation of an event stream from the counter register CNTVCT_EL0:

`0b0` Disables the event stream.

`0b1` Enables the event stream.

When ARMv8.1-VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not enable the event stream.

This field resets to `0`.

EL0VCTEN, bit [1]

Traps EL0 accesses to the frequency register and virtual counter register to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped and reported using EC syndrome value `0x18`:
  - CNTVCT_EL0 and if CNTKCTL_EL1.EL0PCTEN is 0, CNTFRQ_EL0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch32 state, MRC and MCR accesses to the following registers are trapped and reported using EC syndrome value `0x03`, MRRC and MCRR accesses are trapped and reported using EC syndrome value `0x04`:
  - CNTVCT and if CNTKCTL_EL1.EL0PCTEN is 0, CNTFRQ.

`0b0` EL0 accesses to the frequency register and virtual counter registers are trapped.

`0b1` This control does not cause any instructions to be trapped.

When ARMv8.1-VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EL0PCTEN, bit [0]

Traps EL0 accesses to the frequency register and physical counter register to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, the following registers are trapped, reported using EC syndrome value `0x18`:
  - CNTPCT_EL0 and if CNTKCTL_EL1.EL0VCTEN is 0, CNTFRQ_EL0.
- In AArch32 state, MCR or MRC accesses the following registers are trapped, reported using EC syndrome value `0x03`, MCRR or MRRC accesses are trapped and reported using EC syndrome value `0x04`:
  - CNTPCT and if CNTKCTL_EL1.EL0VCTEN is 0, CNTFRQ.

`0b0` EL0 accesses to the frequency register and physical counter register are trapped.

`0b1` This control does not cause any instructions to be trapped.

When ARMv8.1-VHE is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, this control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTKCTL_EL1

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTKCTL_EL1 or CNTKCTL_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTKCTL_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1110	0b0001	0b000

D13.8.16 CNTP_CTL_EL0, Counter-timer Physical Timer Control register

The CNTP_CTL_EL0 characteristics are:

Purpose

Control register for the EL1 physical timer.

Configurations

AArch64 System register CNTP_CTL_EL0[31:0] is architecturally mapped to AArch32 System register CNTP_CTL[31:0].

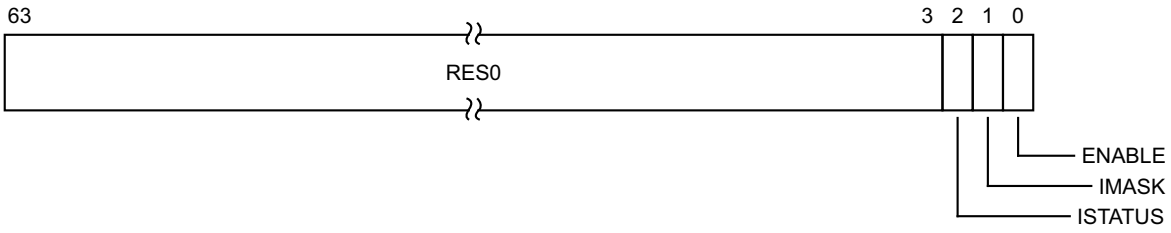
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CTL_EL0 is a 64-bit register.

Field descriptions

The CNTP_CTL_EL0 bit assignments are:



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVAL_EL0 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_CTL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_CTL_EL0 or CNTP_CTL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTP_CTL_EL0

D13.8.17 CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

Configurations

AArch64 System register CNTP_CVAL_EL0[63:0] is architecturally mapped to AArch32 System register CNTP_CVAL[63:0].

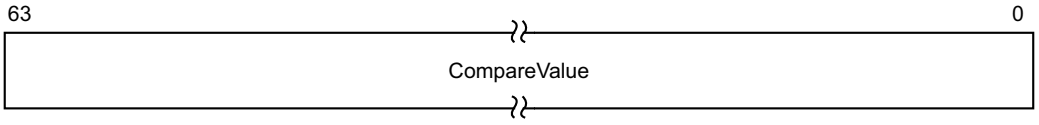
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CVAL_EL0 is a 64-bit register.

Field descriptions

The CNTP_CVAL_EL0 bit assignments are:



CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When CNTP_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTP_CTL_EL0.ISTATUS is set to 1.
- If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTP_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_CVAL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_CVAL_EL0 or CNTP_CVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.18 CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Configurations

AArch64 System register CNTP_TVAL_EL0[31:0] is architecturally mapped to AArch32 System register CNTP_TVAL[31:0].

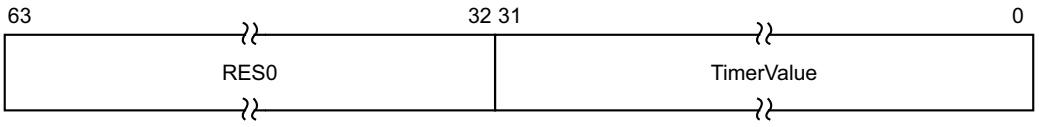
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_TVAL_EL0 is a 64-bit register.

Field descriptions

The CNTP_TVAL_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL_EL0.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL_EL0.ENABLE is 1, the value returned is (CNTP_CVAL_EL0 - CNTPCT_EL0).

On a write of this register, CNTP_CVAL_EL0 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTP_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTP_CTL_EL0.ISTATUS is set to 1.
- If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTP_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_TVAL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTP_TVAL_EL0 or CNTP_TVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.19 CNTPCT_EL0, Counter-timer Physical Count register

The CNTPCT_EL0 characteristics are:

Purpose

Holds the 64-bit physical count value.

Configurations

AArch64 System register CNTPCT_EL0[63:0] is architecturally mapped to AArch32 System register CNTPCT[63:0].

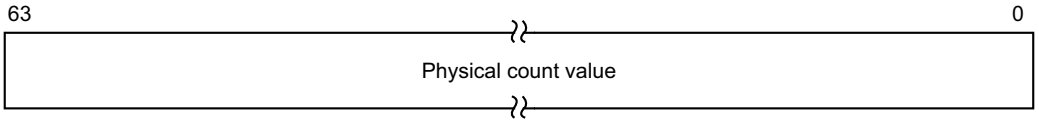
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTPCT_EL0 is a 64-bit register.

Field descriptions

The CNTPCT_EL0 bit assignments are:



Bits [63:0]

Physical count value.

Accessing the CNTPCT_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTPCT_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0000	0b001

D13.8.20 CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register

The CNTPS_CTL_EL1 characteristics are:

Purpose

Control register for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

Configurations

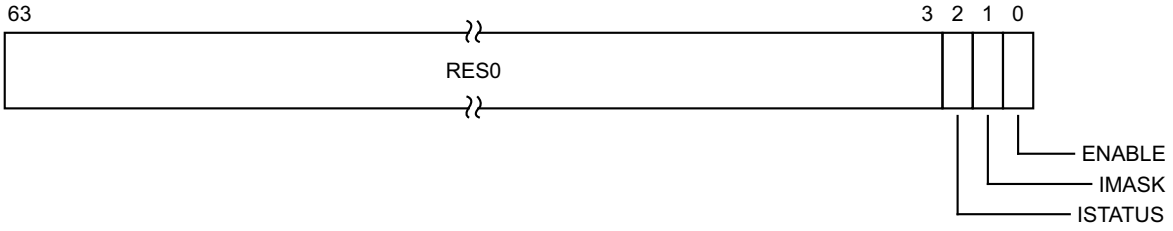
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTPS_CTL_EL1 is a 64-bit register.

Field descriptions

The CNTPS_CTL_EL1 bit assignments are:



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTPS_TVAL_EL1 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTPS_CTL_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTPS_CTL_EL1

op0	op1	CRn	CRm	op2
0b11	0b111	0b1110	0b0010	0b001

D13.8.21 CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register

The CNTPS_CVAL_EL1 characteristics are:

Purpose

Holds the compare value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

Configurations

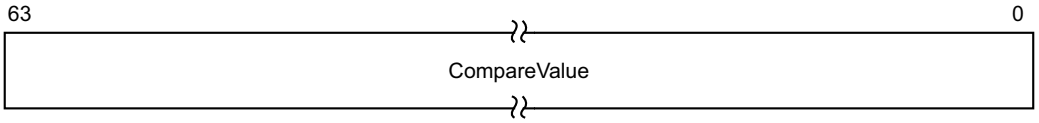
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTPS_CVAL_EL1 is a 64-bit register.

Field descriptions

The CNTPS_CVAL_EL1 bit assignments are:



CompareValue, bits [63:0]

Holds the secure physical timer CompareValue.

When CNTPS_CTL_EL1.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTPS_CTL_EL1.ISTATUS is set to 1.
- If CNTPS_CTL_EL1.IMASK is 0, an interrupt is generated.

When CNTPS_CTL_EL1.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTPS_CVAL_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTPS_CVAL_EL1

op0	op1	CRn	CRm	op2
0b11	0b111	0b1110	0b0010	0b010

D13.8.22 CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register

The CNTPS_TVAL_EL1 characteristics are:

Purpose

Holds the timer value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

Configurations

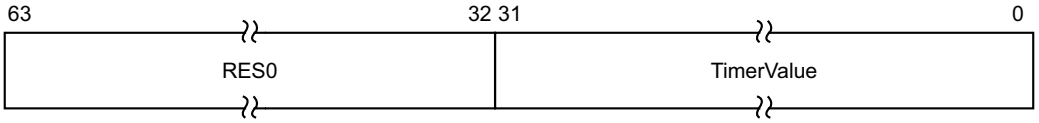
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTPS_TVAL_EL1 is a 64-bit register.

Field descriptions

The CNTPS_TVAL_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the secure physical timer.

On a read of this register:

- If CNTPS_CTL_EL1.ENABLE is 0, the value returned is UNKNOWN.
- If CNTPS_CTL_EL1.ENABLE is 1, the value returned is (CNTPS_CVAL_EL1 - CNTPCT_EL0).

On a write of this register, CNTPS_CVAL_EL1 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTPS_CTL_EL1.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTPS_CVAL_EL1) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTPS_CTL_EL1.ISTATUS is set to 1.
- If CNTPS_CTL_EL1.IMASK is 0, an interrupt is generated.

When CNTPS_CTL_EL1.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTPS_TVAL_EL1

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.23 CNTV_CTL_EL0, Counter-timer Virtual Timer Control register

The CNTV_CTL_EL0 characteristics are:

Purpose

Control register for the virtual timer.

Configurations

AArch64 System register CNTV_CTL_EL0[31:0] is architecturally mapped to AArch32 System register CNTV_CTL[31:0].

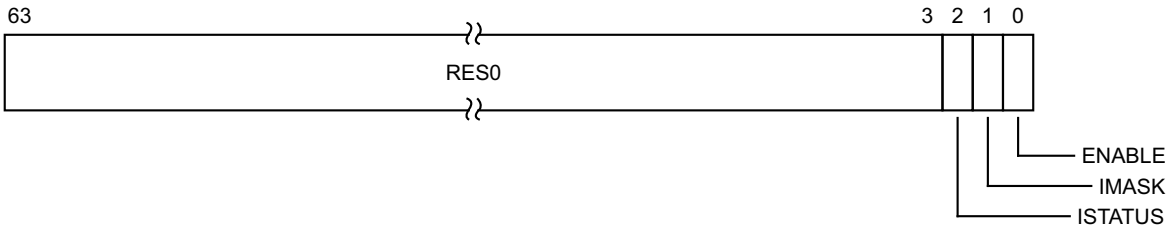
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CTL_EL0 is a 64-bit register.

Field descriptions

The CNTV_CTL_EL0 bit assignments are:



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL_EL0 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_CTL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_CTL_EL0 or CNTV_CTL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

MRS <Xt>, CNTV_CTL_EL0

D13.8.24 CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the virtual timer.

Configurations

AArch64 System register CNTV_CVAL_EL0[63:0] is architecturally mapped to AArch32 System register CNTV_CVAL[63:0].

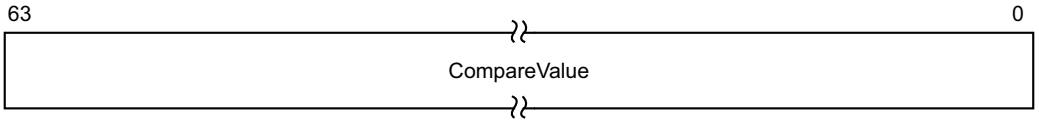
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CVAL_EL0 is a 64-bit register.

Field descriptions

The CNTV_CVAL_EL0 bit assignments are:



CompareValue, bits [63:0]

Holds the EL1 virtual timer CompareValue.

When CNTV_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTV_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_CVAL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_CVAL_EL0 or CNTV_CVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.25 CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 virtual timer.

Configurations

AArch64 System register CNTV_TVAL_EL0[31:0] is architecturally mapped to AArch32 System register CNTV_TVAL[31:0].

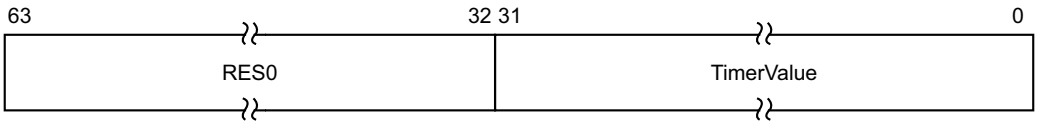
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_TVAL_EL0 is a 64-bit register.

Field descriptions

The CNTV_TVAL_EL0 bit assignments are:



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL1 virtual timer.

On a read of this register:

- If CNTV_CTL_EL0.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL_EL0.ENABLE is 1, the value returned is (CNTV_CVAL_EL0 - CNTVCT_EL0).

On a write of this register, CNTV_CVAL_EL0 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTV_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CNTV_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTV_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_TVAL_EL0

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic CNTV_TVAL_EL0 or CNTV_TVAL_EL02 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.26 CNTVCT_EL0, Counter-timer Virtual Count register

The CNTVCT_EL0 characteristics are:

Purpose

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in CNTPCT_EL0 minus the virtual offset visible in CNTVOFF_EL2.

Configurations

AArch64 System register CNTVCT_EL0[63:0] is architecturally mapped to AArch32 System register CNTVCT[63:0].

The value of this register is the same as the value of CNTPCT_EL0 in the following conditions:

- When EL2 is not implemented.
- When EL2 is implemented, HCR_EL2.E2H is 1, and this register is read from EL2.
- When EL2 is implemented and enabled in the current Security state, HCR_EL2.{E2H, TGE} is {1, 1}, and this register is read from EL0 or EL2.

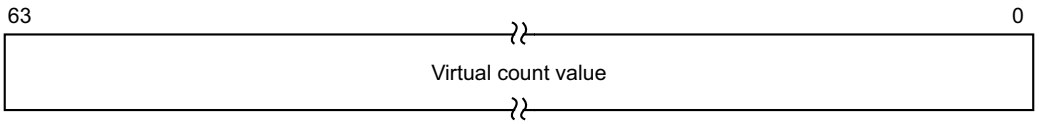
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTVCT_EL0 is a 64-bit register.

Field descriptions

The CNTVCT_EL0 bit assignments are:



Bits [63:0]

Virtual count value.

Accessing the CNTVCT_EL0

Accesses to this register use the following encodings in the System instruction encoding space:

D13.8.27 CNTVOFF_EL2, Counter-timer Virtual Offset register

The CNTVOFF_EL2 characteristics are:

Purpose

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT_EL0 and the virtual count value visible in CNTVCT_EL0.

Configurations

AArch64 System register CNTVOFF_EL2[63:0] is architecturally mapped to AArch32 System register CNTVOFF[63:0].

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

Note

When EL2 is implemented and enabled in the current Security state, and is using AArch64, the virtual counter uses a fixed virtual offset of zero in the following situations:

- HCR_EL2.E2H is 1, and CNTVCT_EL0 is read from EL2.
- HCR_EL2.{E2H, TGE} is {1, 1}, and either:
  - CNTVCT_EL0 is read from EL0 or EL2.
  - CNTVCT is read from EL0.

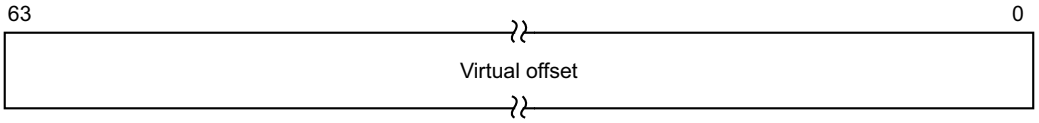
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTVOFF_EL2 is a 64-bit register.

Field descriptions

The CNTVOFF_EL2 bit assignments are:



Bits [63:0]

Virtual offset.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTVOFF_EL2

Accesses to this register use the following encodings in the System instruction encoding space:

Part E
The AArch32 Application Level Architecture

Chapter E1
The AArch32 Application Level Programmers' Model

This chapter gives an Application level description of the programmers' model for software executing in AArch32 state. This means it describes execution in EL0 when EL0 is using AArch32. It contains the following sections:

- *About the Application level programmers' model* on page E1-3782.
- *The Application level programmers' model in AArch32 state* on page E1-3783.
- *Advanced SIMD and floating-point instructions* on page E1-3794.
- *About the AArch32 System register interface* on page E1-3805.
- *Exceptions* on page E1-3806.

E1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for the development of applications that will execute in AArch32 state.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers' model into context.

Depending on the implementation, the architecture supports multiple levels of execution privilege. These privilege levels are indicated by different *Exception levels* that number upwards from EL0, where EL0 corresponds to the lowest privilege level and is often described as *unprivileged*. The Application level programmers' model is the programmers' model for software executing at EL0. For more information see *Armv8 architectural concepts* on page A1-38.

System software determines the Exception level, and therefore the level of privilege, at which application software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged. This has the following effects:

- It means that the operating system can allocate system resources to an application in a unique or shared manner.
- It provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some System level understanding is helpful, and if appropriate it gives a reference to the System level description.

Application level software is generally unaware of its Security state, and of any virtualization. For more information, see *The Armv8-A security model* on page G1-5477 and *The effect of implementing EL2 on the Exception model* on page G1-5482.

Note

- When an implementation includes EL3, application and operating system software normally executes in Non-secure state.
- Older documentation, describing implementations or architecture versions that support only two privilege levels, often refers to execution at EL1 as *privileged* execution.
- In this manual, the terms *CONSTRAINED UNPREDICTABLE*, *IMPLEMENTATION DEFINED*. *OPTIONAL*, *RES0*, *RES1*, *UNDEFINED*, *UNKNOWN*, and *UNPREDICTABLE* have Arm-specific meanings, as defined in the *Glossary*. In body text, these terms are shown in SMALL CAPS, for example IMPLEMENTATION DEFINED.

E1.2 The Application level programmers' model in AArch32 state

The following sections give more information about the Application level programmers' model in AArch32 state:

- *Instruction sets, arithmetic operations, and register files*.
- *Core data types and arithmetic in AArch32 state*.
- *The general-purpose registers, and the PC, in AArch32 state* on page E1-3785.
- *Process state, PSTATE* on page E1-3787.
- *Jazelle support* on page E1-3793.

E1.2.1 Instruction sets, arithmetic operations, and register files

The A32 and T32 instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on a register file of sixteen 32-bit registers, that are comprised of the AArch32 general-purpose registers and the PC. As described in *The general-purpose registers, and the PC, in AArch32 state* on page E1-3785, these registers include the registers SP (R13) and LR (R14), which have specialized uses. *Core data types and arithmetic in AArch32 state* gives more information about these operations.

In addition, an implementation that implements the T32 and A32 instruction sets includes both:

- Scalar floating-point instructions.
- The Advanced SIMD vector instructions.

Floating-point and vector instructions operate on a separate common register file, described in *The SIMD and floating-point register file* on page E1-3794. *Advanced SIMD and floating-point instructions* on page E1-3794 gives more information about these instructions.

E1.2.2 Core data types and arithmetic in AArch32 state

When executing in AArch32 state, a PE supports the following data types in memory:

Byte 8 bits.
Halfword 16 bits.
Word 32 bits.
Doubleword 64 bits.

PE registers are 32 bits in size. The instruction sets provide instructions that use the following data types for data held in registers:

- 32-bit pointers.
- Unsigned or signed 32-bit integers.
- Unsigned 16-bit or 8-bit integers, held in zero-extended form.
- Signed 16-bit or 8-bit integers, held in sign-extended form.
- Two 16-bit integers packed into a register.
- Four 8-bit integers packed into a register.
- Unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

Note

For information about the atomicity of memory accesses see *Atomicity in the Arm architecture* on page E2-3810.

When any of the data types is described as *unsigned*, the N-bit data value represents a non-negative integer in the range 0 to 2^N-1, using normal binary format.

When any of these types is described as *signed*, the N-bit data value represents an integer in the range $-2^{(N-1)}$ to $+2^{(N-1)}$-1, using two's complement format.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The instructions that operate on packed halfwords or bytes include some multiply instructions that use only one of two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

Note

These SIMD instructions operate on values held in the general-purpose registers, and must not be confused with the Advanced SIMD instructions that operate on a separate register file that provides registers of up 128 bits.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more instructions to synthesize them.

Integer arithmetic

The instruction set provides a wide range of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications, and divisions. The pseudocode described in Appendix K13 *Arm Pseudocode Definition* defines these operations, usually in one of three ways:

- By direct use of the pseudocode operators and built-in functions defined in *Operators* on page K13-7790.
- By use of pseudocode helper functions defined in the main text. See Appendix K12 *Pseudocode Index*.
- By a sequence of the form:
  1. Use of the `SInt()`, `UInt()`, and `Int()` built-in functions defined in *Converting bitstrings to integers* on page K13-7802 to convert the bitstring contents of the instruction operands to the unbounded integers that they represent as two's complement or unsigned integers.
  2. Use of mathematical operators, built-in functions and helper functions on those unbounded integers to calculate other such integers.
  3. Use of either the bitstring extraction operator defined in *Bitstring concatenation and slicing* on page K13-7791 or of the saturation helper functions described in *Pseudocode description of saturation* on page E1-3785 to convert an unbounded integer result into a bitstring result that can be written to a register.

Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

Logical Shift Left

The `LSL()` pseudocode function moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Logical Shift Right

The `LSR()` pseudocode function moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Arithmetic Shift Right

The `ASR()` pseudocode function moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Rotate Right The `ROR()` pseudocode function moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

Rotate Right with Extend

The `RRX()` pseudocode function moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Pseudocode description of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand or operands otherwise. For the definition of these operations, see *Addition and subtraction* on page K13-7792.

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions can be synthesized from this status information. In pseudocode the `AddWithCarry()` function provides an addition with a carry input and a set of output Condition flags including carry output and overflow:

An important property of the `AddWithCarry()` function is that if:

```
(result, nzcv) = AddWithCarry(x, NOT(y), carry_in)
```

Then:

- If `carry_in == '1'`, then `result == x-y` with:
  - `nzcv<0> == '1'` if signed overflow occurred during the subtraction.
  - `nzcv<1> == '1'` if unsigned borrow did not occur during the subtraction, that is, if x≥y.
- If `carry_in == '0'`, then `result == x-y-1` with:
  - `nzcv<0> == '1'` if signed overflow occurred during the subtraction.
  - `nzcv<1> == '1'` if unsigned borrow did not occur during the subtraction, that is, if x≥y.

Taken together, this means that the `carry_in` and `nzcv<1>` output in `AddWithCarry()` calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

Pseudocode description of saturation

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo 2^N. This is supported in pseudocode by:

- The `SignedSatQ()` and `UnsignedSatQ()` functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The `SignedSat()` and `UnsignedSat()` functions when only the saturated result is required.

`SatQ(i, N, unsigned)` returns either `UnsignedSatQ(i, N)` or `SignedSatQ(i, N)` depending on the value of its third argument, and `Sat(i, N, unsigned)` returns either `UnsignedSat(i, N)` or `SignedSat(i, N)` depending on the value of its third argument.

E1.2.3 The general-purpose registers, and the PC, in AArch32 state

In the AArch32 Application level view, a PE has:

- Fifteen general-purpose 32-bit registers, R0 to R14, of which R13 and R14 have alternative names reflecting how they are, or can be, used:
  - R13 is usually identified as SP.
  - R14 is usually identified as LR.
- The PC (*program counter*), that can be described as R15.

The specialized uses of the SP (R13), LR (R14), and PC (R15) are:

SP, the stack pointer

The PE uses SP as a pointer to the active stack.

In the T32 instruction set, some instructions cannot access SP. Instructions that can access SP can use SP as a general-purpose register.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The A32 instruction set provides more general access to SP, and it can be used as a general-purpose register.

Note

Using SP for any purpose other than as a stack pointer might break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.

Software can refer to SP as R13.

LR, the link register

The link register can be used to hold return link information, and some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. Software can refer to LR as R14.

PC, the program counter

- When executing an A32 instruction, PC reads as the address of the current instruction plus 8.
- When executing a T32 instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most T32 instructions cannot access PC.

The A32 instruction set provides more general access to the PC, and many A32 instructions can use the PC as a general-purpose register. However, Arm deprecates the use of PC for any purpose other than as the program counter. See *Writing to the PC* for more information.

Software can refer to PC as R15.

See *AArch32 general-purpose registers, the PC, and the Special-purpose registers* on page G1-5489 for the system level view of these registers.

Note

In general, Arm strongly recommends using the names SP, LR and PC instead of R13, R14 and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to *registers R8 to R15*, rather than to *registers R8 to R12, the SP, LR and PC*. These two descriptions of the group of registers have exactly the same meaning.

Writing to the PC

In the A32 and T32 instruction sets, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In T32 state, the following 16-bit T32 instruction encodings branch to the value written to the PC:
  - Encoding T2 of *ADD, ADDS (register)* on page F5-4082.
  - Encoding T1 of *MOV, MOVS (register)* on page F5-4343.

  The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.
- The `B`, `BL`, `CBNZ`, `CBZ`, `CHKA`, `HB`, `HBL`, `HBLP`, `HBP`, `TBB`, and `TBH` instructions remain in the same instruction set state and branch to the value written to the PC.

  The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.
- The `BLX` (immediate) instruction switches between A32 and T32 states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.
- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
  - `BLX` (register), `BX`, and `BXJ`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— `LDR` instructions with `<Rt>` equal to the PC.

— `POP` and all forms of `LDM` except `LDM` (exception return), when the register list includes the PC.

— In A32 state only, `ADC`, `ADD`, `ADR`, `AND`, `ASR` (immediate), `BIC`, `EOR`, `LSL` (immediate), `LSR` (immediate), `MOV`, `MVN`, `ORR`, `ROR` (immediate), `RRX`, `RSB`, `RSC`, `SBC`, and `SUB` instructions with `<Rd>` equal to the PC and without flag-setting specified.

For details of how an interworking address specifies the new instruction set state and instruction address, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

Note

The register-shifted register instructions, that are available only in the A32 instruction set and are summarized in *Data-processing register (register shift)* on page F4-4017, are CONSTRAINED UNPREDICTABLE if they attempt to write to the PC, see *Using R15* on page K1-7607.

- Some instructions are treated as exception return instructions, and write both the PC and the CPSR. For more information, including which instructions are exception return instructions, see *Exception return to an Exception level using AArch32* on page G1-5523.
- Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry.

Pseudocode description of operations on the AArch32 general-purpose registers and the PC

In pseudocode, the uses of the `R[]` function, with an index parameter `n`, are:

- Reading or writing R0-R12, SP, and LR, using n = 0-12, 13, and 14 respectively.
- Reading the PC, using n = 15.

Pseudocode description of general-purpose register and PC operations on page G1-5491 describes accesses to these registers.

Descriptions of A32 store instructions that store the PC value use the `PCStoreValue()` pseudocode function to specify the PC value stored by the instruction.

Writing an address to the PC causes either a simple branch to that address or an *interworking* branch that also selects the instruction set to execute after the branch. A simple branch is performed by the `BranchWritePC()` function.

An interworking branch is performed by the `BXWritePC()` function.

The `LoadWritePC()` and `ALUWritePC()` functions are used for two cases where the behavior was systematically modified between architecture versions.

E1.2.4 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

Note

In this chapter, references to PSTATE link to the more appropriate of:

- The Application-level view of PSTATE given in this section.
- The System-level description in *Process state, PSTATE* on page G1-5493.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

N Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:

- 1 if the result is negative.
- 0 if the result is positive or zero.

Z Zero Condition flag. Set to:

- 1 if the result of the instruction is zero.
- 0 otherwise.

A result of zero often indicates an equal result from a comparison.

C Carry Condition flag. Set to:

- 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
- 0 otherwise.

V Overflow Condition flag. Set to:

- 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
- 0 otherwise.

Conditional instructions test the N, Z, C, and V Condition flags, combining them with the *Condition code* for the instruction, to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see *Conditional execution* on page F2-3909.

The overflow or saturation flag

Q Some instructions can set this. For those instructions that can, the PE:

- Sets it to 1 if the instruction indicates overflow or saturation.
- Leaves it unchanged otherwise.

For more information, see *Pseudocode description of saturation* on page E1-3785.

The greater than or equal flags

GE[3:0] The instructions described in *Parallel addition and subtraction instructions* on page F1-3876 update these to indicate the results from individual bytes or halfwords of the operation. These flags can control a later `SEL` instruction. For more information, see *SEL* on page F5-4500.

PSTATE also contains *PE state controls*. There is no direct access to these from application level instructions, but they can be changed by side-effects of application level instructions. They are:

Instruction set state

J, T The current instruction set state, as shown in Table E1-1. In Armv8, the J bit is RES0, see the Note in this section.

Table E1-1 PSTATE.{J, T} encoding

J	T	Instruction set state
0	0	A32
0	1	T32

A32 The PE is executing the A32 instruction set, summarized in Chapter F4 *A32 Instruction Set Encoding*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T32 The PE is executing the T32 instruction set, summarized in Chapter F3 *T32 Instruction Set Encoding*.

Note

Encoding with J==1 before Armv8, Jazelle and T32EE states

In previous versions of the Arm architecture, the encoding {1, 0} selected Jazelle state, and encoding {1, 1} selected T32EE state. Armv8 does not support either of these states, and these are encodings for unimplemented instruction set states, see *Unimplemented instruction sets* on page G1-5499.

Armv8 AArch32 state requires a Trivial Jazelle implementation, see *Trivial implementation of the Jazelle extension* on page G1-5499.

The IT block state

IT[7:0] The If-Then controls for the T32 `IT` instruction, that applies to the *IT block* of instructions that immediately follow the `IT` instruction. See *IT* on page F5-4204 for a description of the `IT` instruction and its associated `IT` block.

For more information about the use of PSTATE.IT see *Use of PSTATE.IT* on page E1-3791.

Endianness mapping

E For data accesses, controls the endianness:

0 Little-endian.

1 Big-endian.

If an implementation does not provide:

- Big-endian support for data accesses, this bit is RES0.
- Little-endian support for data accesses, this bit is RES1.

Instruction fetches are always little-endian, and ignore PSTATE.E.

Timing control bits

DIT *Data Independent Timing* (DIT) bit. For more information, see *About the DIT bit* on page E1-3793.

This bit is implemented only when ARMv8.4-DIT is implemented.

On a reset to AArch32 state, this bit is set to 0.

Accessing PSTATE fields at EL0

The following sections describe which PSTATE fields can be directly accessed at EL0, and how they can be accessed:

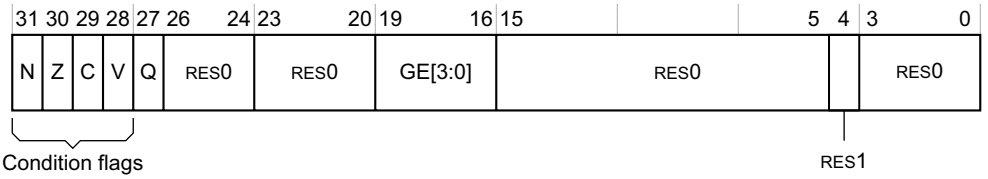
- *The Application Program Status Register, APSR*.
- *The SETEND instruction* on page E1-3790.

The Application Program Status Register, APSR

At EL0, some PSTATE fields can be accessed using the Special-purpose *Application Program Status Register* (APSR). The APSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The APSR bit assignments are:



N, Z, C, V, bits [31:28]

The PSTATE Condition flags.

Q, bit [27] The PSTATE overflow or saturation flag.

Bits[26:24] Reserved, RES0. Software can use `MSR` instructions that write the top byte of the APSR without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

Bits[23:20, 15:0]

Reserved bits that are allocated to system features, or are available for future expansion. Unprivileged execution ignores writes to fields that are accessible only at EL1 or higher. However, application level software that writes to the APSR must treat reserved bits as *Do-Not-Modify* (DNM) bits. For more information about the reserved bits, see *The Current Program Status Register, CPSR* on page G1-5495.

These bits are UNKNOWN on a Read, and it is permitted that, on a read of APSR:

- Bit[22] returns the value of PSTATE.PAN.
- Bit[9] returns the value of PSTATE.E.
- Bits[8:6] return the value of PSTATE.{A,I,F}, the mask bits.
- Bits[4:0] return the value of PSTATE.M[4:0]. Bit[4] is RES1 indicating that the PE is in AArch32 state.

Note

This is an exception to the general rule that an UNKNOWN field must not return information that cannot be obtained, at the current Privilege level, by an architected mechanism.

GE[3:0], bits [19:16]

The PSTATE greater than or equal flags.

The other PSTATE fields cannot be accessed by using the APSR.

The system level alias for the APSR is the CPSR. The CPSR is a superset of the APSR. See *The Current Program Status Register, CPSR* on page G1-5495.

Writes to the PSTATE fields have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the APSR write. This means they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The SETEND instruction

The A32 and T32 instruction sets both include an instruction to manipulate PSTATE.E:

`SETEND BE` Sets PSTATE.E to 1, for big-endian operation.

`SETEND LE` Sets PSTATE.E to 0, for little-endian operation.

The `SETEND` instruction is unconditional. For more information, see *SETEND* on page F5-4502. Arm deprecates use of the `SETEND` instruction.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Use of PSTATE.IT

PSTATE.IT provides the If-Then controls for the T32 `IT` instruction, that applies to the *IT block* of instructions that immediately follow the `IT` instruction.

PSTATE.IT divides into two subfields:

IT[7:5] Holds the *base condition* for the current IT block. The base condition is the top three bits of the Condition code specified by the `<firstcond>` field of the `IT` instruction.

IT[4:0] Encodes:

- Implicitly, the size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is indicated by the position of the least significant 1 in this field, as shown in Table E1-2.
- For each instruction in the IT block, the least significant bit of the Condition code. This is encoded in the IT block entries that Table E1-2 shows as N*x*.

Note

Changing the least significant bit of a Condition code from 0 to 1 has the effect of inverting the Condition code.

Both subfields are all zeros when no IT block is active.

When an `IT` instruction is executed, PSTATE.IT is set according to the `<firstcond>` field of the instruction and the *Then* and *Else* (T and E) parameters in the instruction, see *IT* on page F5-4204. This means that, on executing an IT instruction, the initial state of PSTATE.IT depends on the number of instructions in the IT block, as Table E1-2 shows:

Table E1-2 Initial state of PSTATE.IT on executing an `IT` instruction

Number of instructions in IT block	PSTATE.IT bits[a]						Notes
	[7:5]	[4]	[3]	[2]	[1]	[0]	
4	cond_base	N1	N2	N3	N4	1	-
3	cond_base	N1	N2	N3	1	0	-
2	cond_base	N1	N2	1	0	0	-
1	cond_base	N1	1	0	0	0	-
Not executing an `IT` instruction	000	0	0	0	0	0	No IT block is active

a. Combinations of the IT bits not shown in this table are reserved.

In Table E1-2, N1 refers to the first instruction in the IT block, and N2, N3, and N4 refer to the second, third, and fourth instructions in the IT block if they are present,

When permitted, an instruction in an IT block is conditional, see *Conditional instructions* on page F1-3867 and *Conditional execution* on page F2-3909. The Condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, PSTATE.IT[4:0] is left-shifted by one bit, so that PSTATE[4] always relates to the next instruction to be executed. Table E1-3 on page E1-3792 shows how PSTATE.IT during the execution of an `IT` instruction with four instructions in the IT block.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table E1-3 Updates to PSTATE.IT when executing an IT instruction with a four-instruction IT block

IT block instruction being executed	PSTATE.IT bits						Notes
	[7:5]	[4]	[3]	[2]	[1]	[0]	
First	cond_base	N1	N2	N3	N4	1	-
Second	cond_base	N2	N3	N4	1	0	-
Third	cond_base	N3	N4	1	0	0	-
Fourth	cond_base	N4	1	0	0	0	-
Not executing an IT instruction	000	0	0	0	0	0	No IT block is active

A few instructions, for example BKPT, cannot be conditional and therefore are always executed ignoring the current value of PSTATE.IT.

For details of what happens if an instruction in an IT block takes an exception, see *Overview of exception entry* on page G1-5508.

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in PSTATE.IT advancing to execution where no IT block is active.

For performance reasons, Armv8 deprecates the use of IT other than with a single 16-bit T32 instruction from a specified subset of the 16-bit T32 instructions, see *Partial deprecation of IT* on page F1-3884. In addition, implementations can provide a set of ITD control fields, SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD, to disable these deprecated uses, making them UNDEFINED. When an implementation includes ITD control fields, *Changes to an ITD control by an instruction in an IT block* describes the permitted CONSTRAINED UNPREDICTABLE behaviors if an instruction in an IT block changes the value of an ITD control to disable the use of the IT instruction.

On a branch or an exception return, if PSTATE.IT is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is CONSTRAINED UNPREDICTABLE.

PSTATE.IT affects instruction execution only in T32 state. In A32 state, PSTATE.IT must be 0b00000000, otherwise the behavior is CONSTRAINED UNPREDICTABLE.

For more information see *CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT* on page K1-7608.

Changes to an ITD control by an instruction in an IT block

In an implementation that includes SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD controls, if an instruction in an IT block changes an ITD control so that the IT instruction using the IT block would be disabled, then one of the following behaviors applies:

- The change to the ITD field, once synchronized, has no effect on the execution of instructions in the current IT block, but applies only to any subsequent execution of an IT instruction to which the control applies.
- Synchronizing the change to the ITD field guarantees that all bits of PSTATE.IT are cleared to 0.

In addition, after the change to the ITD field has been synchronized, any remaining instructions in the IT block that would be made UNDEFINED by the new value of ITD are either:

- Executed normally.
- Treated as UNDEFINED.

The choice between the options described in this section is determined by the implementation, and any choice can vary between different changes to an ITD control by an instruction in an IT block.

Non-Confidential

Pseudocode description of PSTATE PE state fields

The pseudocode function `CurrentInstrSet()` returns the current instruction set. The pseudocode function `SelectInstrSet()` selects a new instruction set.

PSTATE.IT advances after normal execution of an IT block instruction. This is described by the `AArch32.ITAdvance()` pseudocode function.

The pseudocode function `InITBlock()` tests whether the current instruction is in an IT block. The pseudocode function `LastInITBlock()` tests whether the current instruction is the last instruction in an IT block.

The `BigEndian()` pseudocode function tests whether big-endian data memory accesses are currently selected.

E1.2.5 About the DIT bit

When the value of CPSR.DIT is 1:

- The instructions listed in CPSR are required to have;
  - Timing which is independent of the values of the data supplied in any of its registers, and the values of the NZCV flags.
  - Responses to asynchronous exceptions which do not vary based on the values supplied in any of their registers, or the values of the NZCV flags.
- All loads and stores have their timing insensitive to the value of the data being loaded or stored.

Note

When the value of CPSR.DIT is 0, the architecture makes no statement about the timing properties of any instructions.

A corresponding DIT bit is added to PSTATE in AArch64 state, and to CPSR in AArch32 state.

When an exception is taken from AArch32 state to AArch32 state, CPSR.DIT is copied to SPSR.DIT.

When an exception is taken from AArch32 state to AArch64 state, CPSR.DIT is copied to SPSR_ELx.DIT.

When an exception returns to AArch32 state from AArch32 state, SPSR.DIT is copied to CPSR.DIT.

When an exception returns to AArch32 state from AArch64 state, SPSR_ELx.DIT is copied to CPSR.DIT.

CPSR.DIT bit can be written using an `MSR` instruction at any exception level in AArch32 state, and read using an `MRS` instruction at any exception level.

E1.2.6 Jazelle support

Armv8 requires AArch32 state to include a trivial implementation of the Jazelle extension, as described in *Trivial implementation of the Jazelle extension* on page G1-5499.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E1.3 Advanced SIMD and floating-point instructions

In general, Armv8 requires implementation of Advanced SIMD and floating-point instructions in the T32 and A32 instruction sets, but see *Implications of not including Advanced SIMD and floating-point support* on page E1-3800.

The Advanced SIMD instructions perform packed *Single Instruction Multiple Data* (SIMD) operations, either integer or single-precision floating-point. The floating-point instructions perform single-precision or double-precision scalar floating-point operations. When ARMv8.2-FP16 is implemented, half-precision floating-point can also be used for data processing.

These instructions permit *floating-point exceptions*, such as Overflow or Divide by Zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. Armv8 also optionally supports the trapping of floating-point exceptions, see *Floating-point exceptions and exception traps* on page G1-5574. For more information about floating-point exceptions see *Floating-point exceptions and exception traps* on page E1-3797.

The Advanced SIMD and floating-point instructions also provide the following conversion functions:

- Between half-precision floating-point and single-precision floating point, in both directions.
- From double-precision, floating point to a signed single precision integer.

Some Advanced SIMD instructions support polynomial arithmetic over {0, 1}, as described in *Polynomial arithmetic over {0, 1}* on page A1-50.

For system level information about the Advanced SIMD and Floating-point implementation see *Advanced SIMD and floating-point support* on page G1-5570.

The following sections give more information about the Advanced SIMD and floating-point instructions:

- *Floating-point standards, and terminology* on page A1-53.
- *The SIMD and floating-point register file*.
- *Data types supported by the Advanced SIMD implementation* on page E1-3796.
- *Advanced SIMD and floating-point System registers* on page E1-3796.
- *Floating-point data types and arithmetic* on page E1-3796.
- *Floating-point exceptions and exception traps* on page E1-3797.
- *Controls of Advanced SIMD operation that do not apply to floating-point operation* on page E1-3800.
- *Implications of not including Advanced SIMD and floating-point support* on page E1-3800.
- *Pseudocode description of floating-point operations* on page E1-3800.

E1.3.1 The SIMD and floating-point register file

The Advanced SIMD and floating-point instructions use the same register file, that comprises 32 registers. This is distinct from the register file that holds the general-purpose registers and the PC.

The Advanced SIMD and floating-point views of the register file are different. The following sections describe these different views. Figure E1-1 on page E1-3795 shows the views of the register file, and the way the word, doubleword, and quadword registers overlap.

Advanced SIMD views of the register file

Advanced SIMD can view this register file as:

- Sixteen 128-bit quadword registers, `Q0-Q15`.
- Thirty-two 64-bit doubleword registers, `D0-D31`.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in `D0` and `D1` and a 128-bit vector in `Q1`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Floating-point views of the register file

The Advanced SIMD and floating-point register file consists of thirty-two doubleword registers, that can be viewed as:

- Thirty-two 64-bit doubleword registers, `D0-D31`. This view is also available to Advanced SIMD instructions.
- Thirty-two 32-bit single word registers, `S0-S31`. Only half of the set is accessible in this view.

Note

In AArch32 state, half-precision floating point values are always represented using the bottom 16 bits of a single word register, `S0-S31`. When a half-precision value is written to a single word register, the top 16 bits of that register are set to 0.

The two views can be used simultaneously.

SIMD and Floating-point register file mapping onto registers

Figure E1-1 shows the different views of the SIMD and floating-point register file, and the relationship between them.

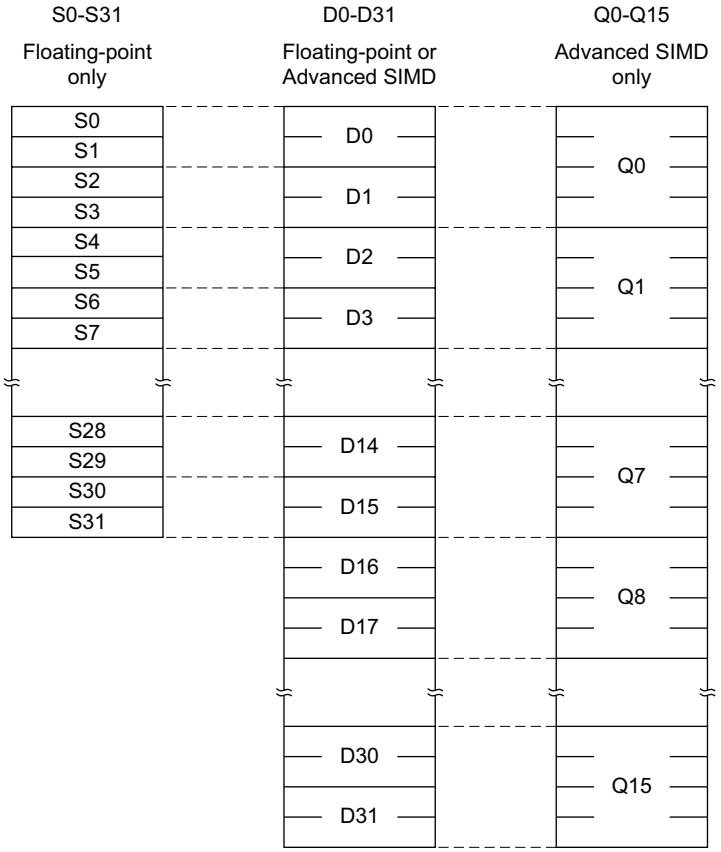

Figure E1-1 SIMD and floating-point register file, AArch32 operation

The mapping between the registers is as follows:

- `S<2n>` maps to the least significant half of `D<n>`.
- `S<2n+1>` maps to the most significant half of `D<n>`.
- `D<2n>` maps to the least significant half of `Q<n>`.
- `D<2n+1>` maps to the most significant half of `Q<n>`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For example, software can access the least significant half of the elements of a vector in Q6 by referring to D12, and the most significant half of the elements by referring to D13.

Pseudocode description of the SIMD and Floating-point register file

The functions _Dclone, S[], and D[] provide the S0-S31, D0-D31, and Q0-Q15 views of the Advanced SIMD and floating-point registers:

The Din[] function returns a Doubleword register from the _Dclone[] copy of the SIMD and Floating-point register file, and the Qin[] function returns a Quadword register from that register file.

Note

The CheckAdvSIMDEnabled() function copies the D[] register file to _Dclone[], see *Pseudocode description of enabling SIMD and floating-point functionality* on page G1-5609.

E1.3.2 Data types supported by the Advanced SIMD implementation

Advanced SIMD instructions can operate on integer and floating-point data, and the implementation defines a set of data types that support the required data formats. *Vector formats in AArch32 state* on page A1-43 describes these formats.

Advanced SIMD vectors

In an implementation that includes support for Advanced SIMD operation, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector. In *Vector formats in AArch32 state* on page A1-43, Figure A1-3 on page A1-45 shows the Advanced SIMD vector formats.

Pseudocode description of Advanced SIMD vectors

The pseudocode function Elem[] accesses the element of a specified index and size in a vector.

E1.3.3 Advanced SIMD and floating-point System registers

The Advanced SIMD and floating-point instructions have a shared register space for System registers. The only register in this space that is accessible at the Application level is the FPSCR.

Writes to the FPSCR can have side-effects on various aspects of PE operation. All of these side-effects are synchronous to the FPSCR write. This means they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

See *Advanced SIMD and floating-point System registers* on page G1-5572 for the system level view of the registers.

These registers can be described as the *SIMD and floating-point System registers*.

E1.3.4 Floating-point data types and arithmetic

The T32 and A32 floating-point instructions support single-precision (32-bit) and double-precision (64-bit) data types and arithmetic as defined by the IEEE 754 floating-point standard. They also support the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types. When ARMv8.2-FP16 is implemented, it also supports the half-precision floating-point data type for data processing operations.

Arm standard floating-point arithmetic means IEEE 754 floating-point arithmetic with the restrictions described in *Advanced SIMD and floating-point support* on page A1-51, including supporting only the input and output values described in *Arm standard floating-point input and output values* on page A1-53.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The AArch32 Advanced SIMD instructions support only single-precision and, when ARMv8.2-FP16 is implemented, half-precision Arm standard floating-point arithmetic.

The following sections describe the Advanced SIMD and floating-point formats:

- *Half-precision floating-point formats* on page A1-45.
- *Single-precision floating-point format* on page A1-47.
- *Double-precision floating-point format* on page A1-48.

The following sections describe features of Advanced SIMD and floating-point processing:

- *Flush-to-zero* on page A1-54.
- *NaN handling and the Default NaN* on page A1-55.

E1.3.5 Floating-point exceptions and exception traps

Arm Advanced SIMD and floating-point instructions record the following floating-point exceptions in the FPSCR cumulative bits, unless the floating-point exception is trapped and generates an exception:

FPSCR.IOC Invalid Operation. The bit is set to 1 if the result of an operation has no mathematical value or cannot be represented. Cases include, for example:

- (infinity) × 0.
- (+infinity) + (–infinity).

These tests are made after flush-to-zero processing. For example, if flush-to-zero mode is selected, multiplying a denormalized number and an infinity is treated as (0 × infinity), and causes an Invalid Operation floating-point exception.

IOC is also set on any floating-point operation with one or more signaling NaNs as operands, except for negation and absolute value, as described in *Floating-point negation and absolute value* on page E1-3801.

FPSCR.DZC Divide by Zero. The bit is set to 1 if a divide operation has a zero divisor and a dividend that is not zero, an infinity or a NaN. These tests are made after flush-to-zero processing, so if flush-to-zero processing is selected, a denormalized dividend is treated as zero and prevents Divide by Zero from occurring, and a denormalized divisor is treated as zero and causes Divide by Zero to occur if the dividend is a normalized number.

For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be +1.0. This means that a zero or denormalized operand to these functions sets the DZC bit.

FPSCR.OFC Overflow. The bit is set to 1 if the absolute value of the result of an operation, produced after rounding, is greater than the maximum positive normalized number for the destination precision.

FPSCR.UFC Underflow. The bit is set to 1 if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, and the rounded result is inexact.

The criteria for the Underflow floating-point exception to occur are different in Flush-to-zero mode. For details, see *Flush-to-zero* on page A1-54.

FPSCR.IXC Inexact. The bit is set to 1 if the result of an operation is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

The criteria for the Inexact floating-point exception to occur are different in Flush-to-zero mode. For details, see *Flush-to-zero* on page A1-54.

FPSCR.IDC Input Denormal. The bit is set to 1 if a denormalized input operand is replaced in the computation by a zero, as described in *Flush-to-zero* on page A1-54.

For Advanced SIMD instructions, and for floating-point instructions when floating-point exception trapping is not supported, these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For floating-point instructions when floating-point exception trapping is supported:

- The floating-point exceptions can be trapped, by setting trap enable bits in the FPSCR, see *Floating-point exceptions and exception traps* on page G1-5574, and:
  - When a trap is not enabled the corresponding floating-point exception updates the corresponding FPSCR cumulative bit does not generate an exception.
  - When a trap is enabled the corresponding floating-point exception does not update the FPSCR, but generates an exception. In this case, bits in the FPEXC indicate which floating-point exceptions have occurred.
- The definition of the Underflow floating-point exception is different in the trapped and cumulative exception cases. In the trapped case the definition is:
  - The trapped Underflow floating-point exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.
- As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in *Combinations of floating-point exceptions*.
- For Invalid Operation floating-point exceptions, for details of which quiet NaN is produced as the default result see *NaN handling and the Default NaN* on page A1-55.
- For Overflow floating-point exceptions, the sign bit of the default result is determined normally for the overflowing operation.
- For Divide by Zero floating-point exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive OR of the sign bits of the two operands.

Table E1-4 shows the results of untrapped floating-point exceptions. That table uses the following abbreviations:

MaxNorm The maximum normalized number of the destination precision.

RM Round towards Minus Infinity mode, as defined in the IEEE 754 standard.

RN Round to Nearest mode, as defined in the IEEE 754 standard.

RP Round towards Plus Infinity mode, as defined in the IEEE 754 standard.

RZ Round towards Zero mode, as defined in the IEEE 754 standard.

For more information about the IEEE 754 descriptions of the rounding modes see *Floating-point standards, and terminology* on page A1-53.

Table E1-4 Results of untrapped floating-point exceptions

Exception type	Default result for positive sign	Default result for negative sign
IOC, Invalid Operation	Quiet NaN	Quiet NaN
DZC, Divide by Zero	+infinity	-infinity
OFC, Overflow	RN, RP: +infinity RM, RZ: +MaxNorm	RN, RM: -infinity RP, RZ: -MaxNorm
UFC, Underflow	Normal rounded result	Normal rounded result
IXC, Inexact	Normal rounded result	Normal rounded result
IDC, Input Denormal	Normal rounded result	Normal rounded result

Combinations of floating-point exceptions

Many pseudocode functions perform *floating-point operations*, including `FixedToFP()`, `FPAdd()`, `FPCompare()`, `FPCompareEQ()`, `FPCompareGE()`, `FPCompareGT()`, `FPDiv()`, `FPMax()`, `FPMin()`, `FPMul()`, `FPMulAdd()`, `FPRecipEstimate()`, `FPRecipStep()`, `FPRSqrtEstimate()`, `FPRSqrtStep()`, `FPSqrt()`, `FPSub()`, and `FPToFixed()`. All of these operations can generate floating-point exceptions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

`FPAbs()` and `FPNeg()` are not classified as *floating-point operations* because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:
  - — *Flush-to-zero* on page A1-54.
  - — *NaN handling and the Default NaN* on page A1-55.

More than one exception can occur on the same operation. The only combinations of floating-point exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other floating-point exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the FPSCR to be set.

When one or more floating-point exceptions caused by an operation is trapped, the behavior of the instruction depends on the priority of the exceptions:

- If the higher priority floating-point exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether any information about the lower priority floating-point exception is provided.

  Note

  Information about the lower priority floating-point exception might be provided in:

  — The FPEXC, if the exception generated by the trap is taken to an Exception level that is using AArch32.

  — The ESR_ELx.ISS field, if the exception generated by the trap is taken to an Exception level that is using AArch64.

  However, information might be provided in another IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

  Apart from this, the lower priority floating-point exception is ignored in this case.

- If the higher priority floating-point exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority floating-point exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is CONSTRAINED UNPREDICTABLE which floating-point exception is treated as higher priority.

For example, a `VMLA.F32` instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact floating-point exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any floating-point exception on the multiplication. The same applies to Invalid Operation floating-point exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal floating-point exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is CONSTRAINED UNPREDICTABLE which of an Input Denormal floating-point exception on the addition and a floating-point exception on the multiplication is treated as higher priority, because the occurrence of the Input Denormal floating-point exception does not depend on the result of the multiplication. The same applies to an Invalid Operation floating-point exception on the addition caused by the addend being a signaling NaN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The VFMA instruction performs a vector addition and a vector multiplication as a single operation. The VFMS instruction performs a vector subtraction and a vector multiplication as a single operation.

E1.3.6 Controls of Advanced SIMD operation that do not apply to floating-point operation

Armv7 permitted implementation of either, both, or neither of the Advanced SIMD and floating-point additions to the base instruction set, and provided some controls that applied to the Advanced SIMD functionality but not to the floating-point functionality. In Armv8, Advanced SIMD functionality cannot be separated from floating-point functionality, but in AArch32 state these controls function as they did in Armv7. This means they apply only to the following instructions and instruction encodings:

- All instructions with encodings defined in:
  - *Advanced SIMD data-processing* on page F3-3962, for the T32 instruction set.
  - *Advanced SIMD data-processing* on page F4-4049, for the A32 instruction set.
- All instructions with encodings defined in:
  - *Advanced SIMD element or structure load/store* on page F3-3985, for the T32 instruction set.
  - *Advanced SIMD element or structure load/store* on page F4-4061, for the A32 instruction set.
- The form of the VDUP instruction described in *VDUP (general-purpose register)* on page F6-4971.
- The byte and halfword forms of the VMOV instructions described in each of:
  - *VMOV (general-purpose register to scalar)* on page F6-5141.
  - *VMOV (scalar to general-purpose register)* on page F6-5145.

The controls of this functionality are:

- The CPACR.ASEDIS field.
- The HCPTR.TASE field.

In an implementation that supports Advanced SIMD functionality, support for each of these controls is optional:

- If the CPACR.ASEDIS control is not supported then the CPACR.ASEDIS field is RAZ/WI. This is equivalent to the control permitting the execution of Advanced SIMD instructions at EL1 and EL0.
- If the HCPTR.TASE control is not supported then the HCPTR.TASE field is RAZ/WI. This means the HCPTR does not provide a control that can trap Non-secure execution of Advanced SIMD instructions to Hyp mode.

E1.3.7 Implications of not including Advanced SIMD and floating-point support

In general, Armv8 requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementation targeting specialized markets, Arm might produce or license an Armv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- Each of the CPACR.{cp10, cp11} fields is RES0.
- The CPACR.ASEDIS bit is RES0.
- Each of the HCPTR.{TASE, TCP10, TCP11} fields is RES1.
- Each of the NSACR.{NSASEDIS, cp10, cp11} fields is RES0.
- The FPEXC register is UNDEFINED.

E1.3.8 Pseudocode description of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the Armv8 architecture:

- *Generation of specific floating-point values* on page E1-3801.
- *Floating-point negation and absolute value* on page E1-3801.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

- *Floating-point value unpacking*.
- *Floating-point exception and NaN handling*.
- *Floating-point rounding*.
- *Selection of Arm standard floating-point arithmetic* on page E1-3802.
- *Floating-point comparisons* on page E1-3802.
- *Floating-point maximum and minimum* on page E1-3802.
- *Floating-point addition and subtraction* on page E1-3802.
- *Floating-point multiplication and division* on page E1-3802.
- *Floating-point fused multiply-add* on page E1-3802.
- *Floating-point reciprocal estimate and step* on page E1-3802.
- *Floating-point square root* on page E1-3803.
- *Floating-point reciprocal square root estimate and step* on page E1-3803.
- *Floating-point conversions* on page E1-3804.

Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The `sign` argument is `'0'` for the positive version and `'1'` for the negative version:

- `FPInfinity()`.
- `FPMaxNormal()`.
- `FPZero()`.
- `FPTwo()`.
- `FPThree()`.
- `FPDefaultNaN()`.

Floating-point negation and absolute value

The floating-point negation and absolute value operations only affect the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

The floating-point negation operation is described by the pseudocode function `FPNeg()`. The floating-point absolute value operation is described by the pseudocode function `FPAbs()`.

Floating-point value unpacking

The `FPUnpack()` function determines the type of a floating-point number, defined by `FPType{}`, and its numerical value. It also does flush-to-zero processing on input operands.

Floating-point exception and NaN handling

The `FPProcessException()` procedure checks whether a floating-point exception is trapped, and handles it accordingly. The floating-point exception types are defined by `FPExc{}`.

The `FPProcessNaN()` function processes a NaN operand, producing the correct result value and generating an Invalid Operation floating-point exception if necessary. The `FPProcessNaNs()` function performs the standard NaN processing for a two-operand operation. The `FPProcessNaNs3()` function performs the standard NaN processing for a three-operand operation.

Floating-point rounding

The `FPRound()` function rounds and encodes a floating-point result to a specified destination format. This includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero processing on result values.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Selection of Arm standard floating-point arithmetic

The `StandardFPSCRValue()` function returns the FPSCR value that selects Arm standard floating-point arithmetic. Most of the arithmetic functions have a Boolean `fpscr_controlled` argument that is `TRUE` for Floating-point operations and `FALSE` for Advanced SIMD operations, and that selects between using the real FPSCR value and this value.

Floating-point comparisons

The `FPCompare()` function compares two floating-point numbers, producing a {N, Z, C, V} Condition flags result as shown in Table E1-5:

Table E1-5 Effect of a Floating-point comparison on the Condition flags

Comparison result	N	Z	C	V
Equal	0	1	1	0
Less than	1	0	0	0
Greater than	0	0	1	0
Unordered	0	0	1	1

This result defines the operation of the `VCMP` floating-point instruction. The `VCMP` instruction writes these flag values in the FPSCR. After using a `VMRS` instruction to transfer them to the APSR, they can control conditional execution as shown in Table F2-1 on page F2-3909.

The `FPCompareEQ()`, `FPCompareGE()`, and `FPCompareGT()` functions describe the operation of Advanced SIMD instructions that perform floating-point comparisons.

Floating-point maximum and minimum

The `FPMax()` function returns the maximum of two floating-point numbers. The `FPMin()` function returns the minimum of two floating-point numbers.

Floating-point addition and subtraction

The `FPAdd()` function adds two floating-point numbers. The `FPSub()` function subtracts one floating-point number from another floating-point number.

Floating-point multiplication and division

The `FPMul()` function multiplies two floating-point numbers. The `FPDiv()` function divides one floating-point number by another floating-point number.

Floating-point fused multiply-add

The `FPMulAdd()` function performs a floating-point fused multiply-add.

Floating-point reciprocal estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of a number.

The `VRECPE` instruction produces the initial estimate of the reciprocal. It uses the pseudocode functions:

- `FPRecipEstimate()`.
- `UnsignedRecipEstimate()`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table E1-6 shows the results where input values are out of range.

Table E1-6 VRECPE results for out of range inputs

Number type	Input Vm[i]	Result Vd[i]
Integer	<= 0x7FFFFFFF	0xFFFFFFFF
Floating-point	NaN	Default NaN
Floating-point	±0 or denormalized number	±infinity [a]
Floating-point	±infinity	±0
Floating-point	Absolute value >= 2^{126}	±0

a. FPSCR.DZC is set to 1

The Newton-Raphson iteration:

$x_{n+1} = x_n(2-dx_n)$

converges to $(1/d)$ if x_0 is the result of VRECPE applied to d.

The VRECPS instruction performs a (2 - op1×op2) calculation and can be used with a multiplication to perform a step of this iteration. The functionality of this instruction is defined by the FPRecipStep() pseudocode function.

Table E1-7 shows the results where input values are out of range.

Table E1-7 VRECPS results for out of range inputs

Input Vn[i]	Input Vm[i]	Result Vd[i]
Any NaN	-	Default NaN
-	Any NaN	Default NaN
±0.0 or denormalized number	±infinity	2.0
±infinity	±0.0 or denormalized number	2.0

Floating-point square root

The FPSqrt() function returns the square root of a floating-point number.

Floating-point reciprocal square root estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of the square root of a number.

The VRSQRTE instruction produces the initial estimate of the reciprocal of the square root. It uses the pseudocode functions:

- FPRSqrtEstimate().
- UnsignedRSqrtEstimate().

Table E1-8 shows the results where input values are out of range.

Table E1-8 VRSQRTE results for out of range inputs

Number type	Input Vm[i]	Result Vd[i]
Integer	<= 0x3FFFFFFF	0xFFFFFFFF
Floating-point	NaN, –(normalized number), –infinity	Default NaN
Floating-point	–0 or –(denormalized number)	– infinity [a]
Floating-point	+0 or +(denormalized number)	+infinity [a]
Floating-point	+infinity	+0

a. FPSCR.DZC is set to 1.

The Newton-Raphson iteration:

$x_{n+1} = x_n(3-dx_n^2)/2$

converges to $(1/\sqrt{d})$ if x_0 is the result of VRSQRTE applied to d.

The VRSQRTS instruction performs a (3 – op1×op2)/2 calculation and can be used with two multiplications to perform a step of this iteration. The functionality of this instruction is defined by the FPRSqrtStep() pseudocode function.

Table E1-9 shows the results where input values are out of range.

Table E1-9 VRSQRTS results for out of range inputs

Input Vn[i]	Input Vm[i]	Result Vd[i]
Any NaN	-	Default NaN
-	Any NaN	Default NaN
±0.0 or denormalized number	±infinity	1.5
±infinity	±0.0 or denormalized number	1.5

FPRSqrtStep() calls the FPHalvedSub() pseudocode function.

Floating-point conversions

The FPConvert() pseudocode function performs conversions between half-precision, single-precision, and double-precision floating-point numbers.

The FPToFixed() and FixedToFP() functions perform conversions between floating-point numbers and integers or fixed-point numbers.

E1.4 About the AArch32 System register interface

AArch32 state provides a System register encoding space, that is indexed by the parameter set {coproc, opc1, CRn, CRm, opc2}, and a set of System register access instructions. This encoding space is used for:

- System registers.
- System instructions, for:
  - Cache and branch predictor maintenance.
  - Address translation.
  - TLB maintenance.

In Armv8, this encoding space uses only the coproc values 0b111x.

Note

The encoding space with coproc values 0b101x is redefined to provide Advanced SIMD and floating-point functionality.

In Armv8:

- The (coproc==0b1111) encodings provide system control functionality, by providing access to System registers and System instructions. This includes architecture and feature identification, as well as control, status information and configuration support.

  The following sections give a general description of these encodings:
  - *About the System registers for VMSAv8-32* on page G5-5850.
  - *VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space* on page G7-5874.
  - *Functional grouping of VMSAv8-32 System registers* on page G5-5856.

  These encodings also provide:
  - The Performance Monitor registers. For more information, see Chapter D7 *The Performance Monitors Extension*.

    The Activity Monitor registers. For more information, see Chapter D8 *The Activity Monitors Extension*.
- The (coproc==0b1110) encodings provide access to additional registers, that support:
  - Debug, see Chapter G2 *AArch32 Self-hosted Debug*.
  - The Jazelle identification registers, see *Jazelle support* on page E1-3793.

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses on page G8-5893 gives information more information about permitted accesses to the System registers in AArch32 state.

Most functionality in the (coproc==0b111x) encoding space cannot be accessed by software executing at EL0. This manual clearly identifies those functions that can be accessed at EL0.

For more information:

- About this encoding space, including the naming of the parameters that index the space, see *The AArch32 System register interface* on page G1-5567.
- About the System interface access instructions, see *System register access instructions* on page F1-3887.

E1.5 Exceptions

The Arm architecture uses the following terms to describe various types of exceptional condition:

Exceptions In the Arm architecture, an *exception* causes entry to EL1, EL2, or EL3. If the Exception level that is entered is using AArch32, it also causes entry to the PE mode in which the exception must be taken. A software handler for the exception is then executed.

Note

The term *floating-point exception* does not use this meaning of *exception*. This term is described later in this list.

Exceptions include:

- Reset.
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- Supervisor calls (SVCs), Secure Monitor calls (SMCs), and hypervisor calls (HVCs).
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-5501. In an Armv8 implementation that includes all the Exception levels, aspects that are visible to application level software are:

- The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at EL1.
- The `SMC` instruction causes a Secure Monitor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Secure Monitor Call exception by methods defined by the operating system, or by another component of the software system that executes at EL1 or higher.
- The `HVC` instruction causes a Hypervisor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at EL1 or higher.
- The `BKPT` instruction causes a Breakpoint Instruction exception, that is taken as a Prefetch Abort exception. This provides a mechanism for a debugger to insert breakpoints into unprivileged software, or for unprivileged software to make a call into a debugger that is accessible at EL1.
- The `WFI` (Wait for Interrupt) instruction provides a hint that nothing needs to be done until an interrupt or another WFI wake-up event occurs, see *Wait For Interrupt* on page G1-5565. This means the hardware might enter a low-power state until the wake-up event occurs.
- The `WFE` (Wait for Event) instruction provides a hint that nothing needs to be done until either an `SEV` instruction generates an event, or another WFE wake-up event occurs, see *Wait For Event and Send Event* on page G1-5562. This means the hardware might enter a low-power state until the wake-up event occurs.

Floating-point exceptions

These relate to exceptional conditions encountered during floating-point arithmetic, such as Divide by Zero or Overflow. For more information see:

- *Floating-point exceptions and exception traps* on page E1-3797.
- The FPEXC and FPSCR register descriptions.
- ANSI/IEEE Std. 754, *IEEE Standard for Binary Floating-Point Arithmetic*.

Chapter E2
The AArch32 Application Level Memory Model

This chapter gives an application level description of the memory model for software executing in AArch32 state. This means it describes the memory model for execution in EL0 when EL0 is using AArch32 in the following sections:

- *About the Arm memory model* on page E2-3808.
- *Atomicity in the Arm architecture* on page E2-3810.
- *Definition of the Armv8 memory model* on page E2-3814.
- *Caches and memory hierarchy* on page E2-3829.
- *Alignment support* on page E2-3834.
- *Endian support* on page E2-3836.
- *Memory types and attributes* on page E2-3840.
- *Mismatched memory attributes* on page E2-3850.
- *Synchronization and semaphores* on page E2-3853

Note

In this chapter, System register names usually link to the description of the register in Chapter G8 *AArch32 System Register Descriptions*, for example SCTLR.

Non-Confidential

E2.1 About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the Armv8 memory model, this introduction is not intended to contradict the definition found in those sections. In general, the basic principles of the Armv8 memory model are:

- To provide a memory model that has similar weaknesses to those found in the memory models used by high-level programming languages such as C or Java. For example, by permitting independent memory accesses to be re-ordered as seen by other observers.
- To avoid the requirement for multi-copy atomicity in the majority of memory types.
- The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the cases where it would be needed.
- The use of address, data, and control dependencies in the creation of order so as to avoid having excessive numbers of barriers or other explicit instructions in common situations where some order is required by the programmer or the compiler.

This section contains:

- *Address space*.
- *Memory type overview*.

E2.1.1 Address space

Address calculations are performed using 32-bit registers. Supervisory software determines the valid address range.

Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo 2^{32}.

The result of an address calculation is UNKNOWN if it overflows or underflows the 32-bit address range A[31:0].

Memory accesses use the `MemA[]`, `MemO[]`, `MemU[]`, and `MemU_unpriv[]` pseudocode functions:

- The `MemA[]` function makes an aligned access of the required type.
- The `MemO[]` function makes an ordered access of the required type.
- The `MemU[]` function makes an unaligned access of the required type
- The `MemU_unpriv[]` function makes an unaligned, unprivileged access of the required type.

Each of these functions calls `Mem_with_type[]` function, that specifies the required access. This calls `AArch32.MemSingle[]`, which performs an atomic, little-endian read of `size` bytes.

The `AccType` enumeration defines the different access types.

Note

- Chapter G4 *The AArch32 System Level Memory Model* and Chapter G5 *The AArch32 Virtual Memory System Architecture* include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also reference pseudocode descriptions of these operations.
- For references to the pseudocode that relates to memory accesses, see *Basic memory access* on page G4-5715, *Unaligned memory access* on page G4-5716, and *Aligned memory access* on page G4-5715.

E2.1.2 Memory type overview

Armv8 provides the following mutually-exclusive memory types:

Normal This is generally used for bulk memory operations, both read-write and read-only operations.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Device The Arm architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page E2-3846.
- They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See *Reordering* on page E2-3847
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page E2-3848.

For more information on Normal memory and Device memory, see *Memory types and attributes* on page E2-3840.

Note

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-Ordered memory type. A Note in *Device memory* on page E2-3844 describes how these memory types map onto the Armv8 memory types.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The Arm architecture description refers to two types of atomicity, *single-copy atomicity* and *multi-copy atomicity*. In the Armv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information see:

- *Requirements for single-copy atomicity*.
- *Properties of single-copy atomic accesses* on page E2-3811.
- *Multi-copy atomicity* on page E2-3811.
- *Requirements for multi-copy atomicity* on page E2-3812.
- *Concurrent modification and execution of instructions* on page E2-3812.

For more information about the memory types, see *Memory type overview* on page E2-3808.

E2.2.1 Requirements for single-copy atomicity

In AArch32 state, the single-copy atomic PE accesses are:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.
- Memory accesses caused by `LDREXD` and `STREXD` instructions to doubleword-aligned locations.

`LDM`, `LDC`, `LDRD`, `STM`, `STC`, `STRD`, `PUSH`, `POP`, `RFE`, `SRS`, `VLDM`, `VLDR`, `VSTM`, and `VSTR` instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

`LDRD` and `STRD` accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables.

Note

This requirement has been added to avoid the need for complex measures to avoid atomicity issues when changing translation table entries, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.
- Software must ensure that translation tables are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.

Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- The element size is 32 bits, or smaller.
- The elements are naturally aligned.

Accesses to 64-bit elements or structures that are 32-bit aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic. The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When an access is not single-copy atomic by the rules described in this section, it is executed as a sequence of one or more accesses that aggregate to the size of the original access. Each of the accesses in this sequence is single-copy atomic, at least at the byte level.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

In this section, the terms *before the write operation* and *after the write operation* mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

If, according to these rules, an instruction is executed as a sequence of accesses, a synchronous Data Abort exception or Debug state entry can be taken during that sequence. This causes execution of the instruction to be abandoned. See *Data Abort exception* on page G1-5547 and, when ARMv8.2-LSMAOC is implemented, *Taking an interrupt or other exception during a multiple-register load or store* on page G1-5535.

If the synchronous Data Abort exception is returned from using the preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that was performed before the exception was taken is repeated. This also applies to an exit from Debug state.

Note

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

For implicit accesses:

- Cache linefills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.
- Instruction fetches are single-copy atomic:
  - At 32-bit granularity in A32 state.
  - At 16-bit granularity in T32 state.

  Concurrent modification and execution of instructions on page E2-3812 describes additional constraints on the behavior of instruction fetches.
- Translation table walks are performed using accesses that are single-copy atomic:
  - At 32-bit granularity when using Short-descriptor format translation tables.
  - At 64-bit granularity when using Long-descriptor format translation tables.

E2.2.2 Properties of single-copy atomic accesses

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.
2. For a single-copy atomic load instruction L_1 that overlaps a single-copy atomic store instruction S_2, if one of the overlapping reads generated by L_1 Reads-from one of the overlapping writes generated by S_2, then none of the overlapping writes generated by S_2 are Coherence-after the corresponding overlapping reads generated by L_1.

For more information, see *Definition of the Armv8 memory model* on page E2-3814.

E2.2.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Writes that are not coherent are not multi-copy atomic.

E2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The Armv8 memory model is Other-multi-copy atomic. For more information, see *Ordering constraints* on page E2-3818.

E2.2.5 Concurrent modification and execution of instructions

The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification and the instruction after modification are:

- When executing the A32 instruction set, a `B`, `BKPT`, `BL`, `HVC`, `ISB`, `NOP`, `SMC`, or `SVC` instruction.
- When executing the T32 instruction set. a 16-bit `B`, `BKPT`, `BLX`, `BX`, `NOP`, or `SVC` instruction.

In addition, for the 32-bit T32 instructions, for which *Instruction encodings* on page F2-3904 describes the meaning of {`hw1`, `hw2`}:

- `hw1` of a 32-bit `BL` (immediate) instruction can be concurrently modified to `hw1` of another `BL` (immediate) instruction:
  - This means that some of the most significant bits of the immediate value can be modified.
- `hw1` of a 32-bit `BLX` (immediate) instruction can be concurrently modified to `hw1` of another `BLX` immediate instruction:
  - This means that some of the most significant bits of the immediate value can be modified.
- `hw1` of a 32-bit `BL` (immediate) or `BLX` (immediate) instruction can be concurrently modified to a T32 16-bit `B`, `BX`, `BLX`, `BKPT`, or `SVC` instruction. This modification also works in reverse.
- `hw2` of a 32-bit `BL` (immediate) instruction can be concurrently modified to `hw2` of another `BL` (immediate) instruction with a different immediate:
  - This means that some bits of the immediate value, including the least significant bits, can be modified.
- `hw2` of a 32-bit `BLX` (immediate) instruction can be concurrently modified to `hw2` of another `BLX` (immediate) instruction with a different immediate:
  - This means that some bits of the immediate value, including the least significant bits, can be modified.
- `hw2` of a 32-bit `B` (immediate) instruction with a condition field can be concurrently modified to `hw2` of another 32-bit `B` (immediate) instruction with a condition field with a different immediate:
  - This means that some bits of the immediate value, including the least significant bits, can be modified.
- `hw2` of a 32-bit `B` (immediate) instruction without a condition field can be concurrently modified to `hw2` of another 32-bit `B` (immediate) instruction without a condition field:
  - This means that some bits of the immediate value, including the least significant bits, can be modified.

Note

- In the T32 instruction set:
  - The only encodings of `BKPT` and `SVC` are 16-bit.
  - The only encoding of `BL` is 32-bit.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The ISB instruction can be concurrently modified and executed in the A32 and A64 instruction sets, but not in the T32 instruction set.

For the instructions explicitly identified in this section, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

The instructions to which this applies are the B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.

For both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the *always* condition.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.

2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

```
; Coherency example for self-modifying code
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first
; line instead of STR for a 16-bit instruction.
STR <Rt>, [Rn]
DCCMVAU Rn              ; Clean data cache by MVA to point of unification (PoU)
DSB                     ; Ensure visibility of the data stored
ICIMVAU Rn              ; Invalidate instruction cache by VA to PoU
BPIMVA Rn               ; Invalidate branch predictor by MVA to PoU
DSB
```

   Note

   - The DCCMVAU operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
   - If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.

   ---

3. In a multiprocessor system, the ICIMVAU and BPIMVA are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

```
ISB                             ; Synchronize fetched instruction stream
```

For more information about the required synchronization operation, see *Synchronization and coherency issues between data and instruction accesses* on page E2-3831.

For information about memory accesses caused by instruction fetches, see *Ordering constraints* on page E2-3818.

E2.3 Definition of the Armv8 memory model

This section describes observation and ordering in the Armv8 memory model. It contains the following subsections:

- *Locations*.
- *Ordering and observability* on page E2-3815.
- *Ordering constraints* on page E2-3818.
- *Completion and endpoint ordering* on page E2-3819.
- *Ordering of instruction fetches* on page E2-3820.
- *Restrictions on the effects of speculation* on page E2-3821.
- *Memory barriers* on page E2-3823.

For more information on endpoint ordering of memory accesses, see *Reordering* on page E2-3847.

In the Armv8 memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see *Memory types and attributes* on page E2-3840.

The Armv8 architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:

- Chapter G4 *The AArch32 System Level Memory Model*.
- Chapter G5 *The AArch32 Virtual Memory System Architecture*.

See also *Mismatched memory attributes* on page E2-3850.

E2.3.1 Locations

The Armv8 memory model provides a set of definitions that are used to construct conditions on the permitted sequences of accesses to memory. The Armv8 memory model defines:

- The ordering of observation of memory accesses between different observers.
- The ordering of arrival of memory accesses arriving at an endpoint.
- The mechanisms to control the ordering of observation of memory accesses and the arrival of memory accesses at an endpoint.

Locations, Memory effects, and Observers

The Armv8 memory model provides the following definition of a *Location* in memory:

Location

A *Location* refers to a single byte in memory.

As part of its execution an instruction might generate a Memory effect. Observers in the system might observe the Memory effects of that instruction on a Location. The Armv8 memory model provides the following definitions of a Memory effect and an Observer:

Memory effect

The *Memory effects* of an instruction are the read, write, or barrier effects of that instruction. For an instruction that accesses memory:

- A read effect is generated for each Location that is read by the instruction.
- A write effect is generated for each Location that is written by the instruction.

An instruction can generate both read and write effects.

The memory effects of an instruction I_1 are said to appear in program order before the Memory effects of instruction I_2 if and only if I_1 occurs before I_2 in program order.

For the purposes of describing the Armv8 memory model, all read and write effects access only Normal memory locations in a Common Shareability Domain. Where this section refers to a read, write, or memory barrier without any qualification, then it is referring to the corresponding Memory effect.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Observer

An *Observer* refers to either a processing element, or some other memory accessing agent that can generate reads from or writes to memory.

Common Shareability Domain

A *Common Shareability Domain* for a program is the smallest Shareability domain that contains all of the active Observers of the Memory effects generated by a program.

E2.3.2 Ordering and observability

The Armv8 memory model permits reordering of memory accesses. This section defines the permitted reordering of memory accesses using the following:

- Register value dependencies to establish order between instructions on a PE.
- Ordering constraints to establish order between accesses to a Location.

Register value dependencies

The Armv8 memory model defines the following dependencies between instructions:

Register dependency

A *Register dependency* from a first data value V_1 to a second data value V_2 exists within a PE if and only if either:

- The register, excluding the AArch64 zero register (XZR or WZR), that is used to hold V_1 is used in the calculation of V_2.
- There is a Register dependency from V_1 to a third data value V_3 and there is a register dependency from V_3 to V_2.

Register data dependency

A *Register data dependency* from a first data value V_1 to a second data value V_2 exists within a PE if and only if either:

- The register, excluding the AArch64 zero register (XZR or WZR) and the AArch32 PC, that is used to hold V_1 and is used in the calculation of V_2, and the calculation between V_1 and the V_2 does not consist of either:
  - A conditional branch whose condition is determined by V_1.
  - A conditional selection, move, or computation whose condition is determined by V_1, where the input data values for the selection, move, or computation do not have a data dependency on V_1.
- There is a Register data dependency from V_1 to a third data value V_3, and there is a Register data dependency from V_3 to V_2.

Address dependency

An *Address dependency* from a read R_1 to a subsequent read R_2 exists if and only if there is a Register data dependency from the data value that is returned by R_1 to the address used by R_2.

An *Address dependency* from a read R_1 to a subsequent write W_2 exists if and only if there is a Register dependency from the data value that is returned by R_1 to the address used by W_2.

Data dependency

A *Data dependency* from a read R_1 to a subsequent write W_2 exists if and only if there is a Register dependency from the data value returned by R_1 to the data value written by W_2.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Control dependency

A *Control dependency* from a read R_1 to a subsequent instruction I_2 exists if and only if either:

- There is a Register dependency from the data value returned by R_1 to the data value used in the evaluation of a conditional branch, and I_2 is only executed as a result of one of the possible outcomes of that conditional branch.
- There is a Register dependency from the data value returned by R_1 to the data value used in the determination of a synchronous exception on an instruction I_3, and I_2 appears in program order after I_3.

Ordering and observability at a Location

Memory effects on a Location are related by the following relations:

Reads-from

A *Reads-from* relation that couples reads and writes to the same Location such that each read is paired with a single write in the program. If a read R_2 of a Location Reads-from a write W_1 to the same Location if and only if R_2 takes its data from W_1.

Note

The Reads-from relation represents a read being satisfied by a write and then returning the written data.

Coherence order

A *Coherence order* relation for each Location in the program that provides a total order on all writes from all coherent Observers to that Location, starting with a notional write of the initial value.

Note

The Coherence order of a Location represents the order in which writes to the Location arrive at memory.

Coherence-after

A write W_2 to a Location is *Coherence-after* another write W_1 to the same Location if and only if W_2 is sequenced after W_1 in the Coherence order of the Location.

A write W_2 to a Location is Coherence-after a read R_1 of the same location if and only if R_1 Reads-from a write W_3 to the same Location and W_2 is Coherence-after W_3.

Overlapping accesses

Two Memory effect overlap if and only if they access the same Location. Two instructions overlap if and only if one or more of their generated Memory effects overlap.

Observed-by

A read or a write RW_1 from an Observer is *Observed-by* a write W_2 from a different Observer if and only if W_2 is coherence-after RW_1.

A write W_1 from an Observer is Observed-by a read R_2 from a different Observer if and only if R_2 Reads-from W_1.

Note

The Observed-by relation only relates accesses generated by different Observers.

`DMB FULL`

A `DMB FULL` is a `DMB` with neither the `LD` or the `ST` qualifier.

Where this section refers to `DMB` without any qualification, then it is referring to all types of `DMB`. Unless a specific shareability domain is defined, a `DMB` applies to the Common Shareability Domain.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All properties that apply to `DMB` also apply to the corresponding `DSB`.

Ordering relations

In addition to the ordering relations that describe order at a location, the Armv8 memory model also provides ordering relations to describe the ordering of instructions. These are as follows:

Dependency-ordered-before

A dependency creates externally-visible order between a read and another Memory effect generated by the same Observer. A read R_1 is *Dependency-ordered-before* a read or write RW_2 from the same Observer if and only if R_1 appears in program order before RW_2 and any of the following cases apply:

- There is an Address dependency or a Data dependency from R_1 to RW_2.
- RW_2 is a write W_2 and there is a Control dependency from R_1 to W_2.
- RW_2 is a read R_2 generated by an instruction appearing in program order after an instruction I_3 that generates a Context synchronization event, and there is a Control dependency from R_1 to I_3.
- RW_2 is a write W_2 appearing in program order after a read or a write RW_3 and there is an Address dependency from R_1 to RW_3.
- RW_2 is a write W_2 that is Coherence-after a write W_3 and there is a Control dependency or a Data dependency from R_1 to W_3.
- RW_2 is a read R_2 that Reads-from a write W_3 and there is an Address dependency or a Data dependency from R_1 to W_3.

Atomic-ordered-before

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A read or a write RW_1 is *Atomic-ordered-before* a read or a write RW_2 from the same Observer if and only if RW_1 appears in program order before RW_2 and either of the following cases apply:

- RW_1 is a read R_1 and RW_2 is a write W_2 such that R_1 and W_2 are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same Location.
- RW_1 is a write W_1 generated by an atomic instruction or a successful Store-Exclusive instruction and RW_2 is a read R_2 generated by an instruction with Acquire semantics such that R_2 Reads-from W_1.

For more information, see *Synchronization and semaphores* on page E2-3853.

Barrier-ordered-before

Barrier instructions order prior Memory effects before subsequent Memory effects generated by the same Observer. A read or a write RW1 is *Barrier-ordered-before* a read or a write RW_2 from the same Observer if and only if RW1 appears in program order before RW_2 and any of the following cases apply:

- RW_1 appears in program order before a `DMB FULL` that appears in program order before RW_2.
- At least one of RW_1 and RW_2 is generated by an atomic instruction with both Acquire and Release semantics.
- RW_1 is a write W_1 generated by an instruction with Release semantics and RW_2 is a read R_2 generated by an instruction with Acquire semantics.
- RW_1 is a read R_1 and either:
  - R_1 appears in program order before a `DMB LD` that appears in program order before RW_2.
  - R_1 is generated by an instruction with Acquire semantics.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- RW_2 is a write W_2 and either:
  - — RW_1 is a write W_1 appearing in program order before a `DMB ST` that appears in program order before W_2.
  - — W_2 is generated by an instruction with Release semantics.
  - — RW_1 appears in program order before a write W_3 generated by an instruction with Release semantics and W_2 is Coherence-after W_3.

Ordered-before

An arbitrary pair of Memory effects is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A read or a write RW_1 is *Ordered-before* a read or a write RW_2 if and only if any of the following cases apply:

- RW_1 is Observed-by RW_2.
- RW_1 is Dependency-ordered-before RW_2.
- RW_1 is Atomic-ordered-before RW_2.
- RW_1 is Barrier-ordered-before RW_2.
- RW_1 is Ordered-before a read or a write that is Ordered-before RW_2.

E2.3.3 Ordering constraints

The Armv8 memory model is described as being Other-multi-copy atomic. The definition of Other-multi-copy atomic is as follows:

Other-multi-copy atomic

In an *Other-multi-copy atomic* system, it is required that a write from an Observer, if observed by a different Observer, is then observed by all other Observers that access the Location coherently. It is, however, permitted for an Observer to observe its own writes prior to making them visible to other observers in the system.

The Other-multi-copy atomic property of the Armv8 memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be *architecturally well-formed*. An implementation that is executing a program is only permitted to exhibit behavior consistent with an architecturally well-formed execution.

Architecturally well-formed

An architecturally well-formed execution must satisfy both of the following requirements:

Internal visibility requirement

For a read or a write RW_1 that appears in program order before a read or a write RW_2 to the same Location, the internal visibility requirement requires that exactly one of the following statements is true:

- RW_2 is a write W_2 that is Coherence-after RW_1.
- RW_1 is a write W_1 and RW_2 is a read R_2 such that either:
  - — R_2 Reads-from W_1.
  - — R_2 Reads-from another write that is Coherence-after W_1.
- RW_1 and RW_2 are both reads R_1 and R_2 such that R_1 Reads-from a write W_3 and either:
  - — R_2 Reads-from W_3.
  - — R_2 Reads-from another write that is Coherence-after W_3.

Note

Informally, if a Memory effect M_1 from an Observer appears in program order before a Memory effect M_2 from the same Observer, then M_1 will be seen to occur before M_2 by that Observer.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

External visibility requirement

For a read or a write RW_1 from an Observer that is Ordered-before a read or a write RW_2 from a different Observer, the external visibility constraint requires that RW_2 is not Observed-by RW_1. This means that an Architecturally well-formed execution must not exhibit a cycle in the Ordered-before relation.

Note

If a Memory effect M_1 from an Observer is Ordered-before another Memory effect M_2, from a different Observer, then M_1 will be seen to occur before M_2 by all Observers in the system.

E2.3.4 Completion and endpoint ordering

Interaction between Observers in a system is not restricted to communication via shared variables in coherent memory. For example, an Observer could configure an interrupt controller to raise an interrupt on another Observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different Observers. When these forms of interaction are used in conjunction with shared variables, a `DSB` instruction can be used to enforce ordering between them.

For all memory, the completion rules are defined as:

- A read R_1 to a Location is complete for a shareability domain when all of the following are true:
  - Any write to the same Location by an Observer within the shareability domain will be Coherence-after R_1.
  - Any translation table walks associated with R_1 are complete for that shareability domain.
- A write W_1 to a Location is complete for a shareability domain when all of the following are true:
  - Any write to the same Location by an Observer within the shareability domain will be Coherence-after W_1.
  - Any read to the same Location by an Observer within the shareability domain will either Reads-from W_1 or Reads-from a write that is Coherence-after W_1.
  - Any translation table walks associated with the write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses, including the updates to translation table entries, associated with the translation table walk are complete for that shareability domain, and the TLB is updated.
- A cache or branch predictor maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.
- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache, branch predictor, or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the `DSB` operation that is required to guarantee visibility of the maintenance instruction.

Note

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side-effects is complete only when the read or write both:

- Can begin to affect the state of the Memory-mapped peripheral.
- Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and write to a peripheral which is defined as the Peripheral coherence order:

Memory-mapped peripheral

A *Memory-mapped peripheral* occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side-effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

Peripheral coherence order

The *Peripheral coherence order* of a Memory-mapped peripheral is a total order on all reads and writes to that peripheral.

Note

The Peripheral coherence order for a Memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.

For a read or a write RW_1 and a read or a write RW_2 to the same peripheral, then RW_1 will appear in the Peripheral coherence order for the peripheral before RW_2 if either of the following cases apply:

- RW_1 and RW_2 are accesses using Non-cacheable or Device attributes and RW_1 is Ordered-before RW_2.
- RW_1 and RW_2 are accesses using Device-nGnRE or Device-nGnRnE attributes and RW_1 appears in program order before RW_2.

Out-of-band-ordered-before

A read or a write RW_1 is *Out-of-band-ordered-before* a read or a write RW_2 if and only if either of the following cases apply:

- RW_1 appears in program order before a `DSB` instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of RW_2.
- RW_1 is Ordered-before a read or a write RW_3 and RW_3 is Out-of-band-ordered-before RW_2.

If a Memory effect M_1 is Out-of-band-ordered-before a read or a write M_2, then M_1 is seen to occur before M_2 by all Observers.

E2.3.5 Ordering of instruction fetches

For two memory locations A and B, if A has been written to and been made coherent with the instruction fetches of the shareability domain, before an update to B by an observer in the same shareability domain, then the instruction stream of each observer in the shareability domain will not see the updated value of B without also seeing the updated value of A.

A write has been made coherent with an instruction fetch of a shareability domain when:

CTR.{DIC, IDC} == {0, 0}

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} == {1, 0}

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain.

CTR.{DIC, IDC} == {0, 1}

The write is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} == {1, 1}

The write is complete for the shareability domain.

Note

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
  - When CTR.DIC == 0, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the `ICIMVAU` instructions of a different core.
  - When CTR.DIC == 1, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.

E2.3.6 Restrictions on the effects of speculation

This section covers restrictions on speculation effects, including:

- *Restrictions on the effects of speculation in Armv8.0*.
- *Speculative Store Bypass Safe (SSBS)* on page E2-3822.
- *Further restrictions on the effects of speculation in Armv8.5* on page E2-3822.

Restrictions on the effects of speculation in Armv8.0

The Armv8.0 architecture places certain restrictions on the effects of speculation. These are:

- Each load from a location using a particular VA after an exception return that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception exit.
- Each load from a location using a particular VA after an exception entry that is a Context synchronization event will not speculatively read an entry from earlier in the coherence order for the location being loaded from than the entry generated by the latest store to that location using the same VA before the exception entry .
- Any load from a location using a particular VA before an exception entry that is a Context synchronization event will not speculatively read data from a store to the same location using the same VA after the exception entry.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Any load from a location using a particular VA before an exception return that is a Context synchronization event will not speculatively read data from a store to the same location using the same VA after the exception exit.
- When data is loaded under speculation with a translation fault, it cannot be used to form an address or generate condition codes to be used by instructions newer than the load in the speculative sequence.
- When data is loaded under speculation from a location without a translation for the translation regime being speculated in, the data cannot be used to form an address or generate condition codes to be used by instructions newer than the load in the speculative sequence.

Speculative Store Bypass Safe (SSBS)

When ARMv8.0-SSBS is implemented, CPSR.SSBS is a control that can be set by software to indicate whether hardware is permitted to load or store speculatively in such a manner that could be exploited to produce a cache timing side channel, which uses an address derived from a register value that has been loaded from memory using a load instruction that speculatively read an entry for the location being loaded from, where the entry that is speculatively read is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

When the value of CPSR.SSBS is 0, hardware is not permitted to load or store speculatively in this way.

When the value of CPSR.SSBS is 1, hardware is permitted to load or store speculatively in this way.

Note

- If speculation is permitted, then cache timing side channels can lead to addresses being derived using reads of address values that have been speculatively loaded from memory to a register.
- Software written for architectures from Armv8.0 to Armv8.4 will set SPSR.SSBS to 0. This means that CPSR.SSBS will not set, so hardware will not be permitted to use speculative loads with outstanding memory disambiguation issues for any subsequent speculative memory accesses if there is any possibility of those subsequent memory accesses creating a cache timing side channel.

Further restrictions on the effects of speculation in Armv8.5

From Armv8.5 there are some further restrictions on the effects of speculation in addition to those in Armv8.0:

- Data loaded under speculation with a permission or domain fault cannot be used to form an address or to generate condition codes to be used by instructions newer than the load in the speculative sequence.
- Any System register read under speculation to a register that is not architecturally accessible from the current Exception level cannot be used to form an address or to generate condition codes to be used by instructions newer than the load in the speculative sequence.

  Note

  As the effects of speculation are not architecturally visible, this restriction level requires that the effect of any speculation cannot give rise to side channels that will leak the values of memory locations, System registers, or Special-purpose registers to a level of privilege that would otherwise not be able to determine those values.

- For all execution prediction resources that predict address or register values, speculative execution at one hardware defined context should be separated in a hard-to-determine manner from the predictions trained in a different hardware defined context. In the case of this definition, the hardware defined context is determined by:
  - The Exception level.
  - The Security state.
  - When executing at EL1, the VMID.
  - When executing at EL0 and using the EL1&0 translation regime, the ASID and the VMID.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— When executing at EL0 and using the EL2&0 translation regime, the ASID.

Note

- The definition of "hard-to-determine manner" is left open to implementations. Examples could include the complete separation of prediction resources, or the isolation of the predictions using a cryptographic or pseudo-random mechanism to separate each context.
- The architecture does not require that prediction resources that simply predict the direction of a branch are separated in this way.

E2.3.7 Memory barriers

The Arm architecture is a weakly ordered memory architecture that supports out of order completion. *Memory barrier* is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the Armv8 architecture provide a range of functionality, including:

- Ordering of Load/Store instructions.
- Completion of Load/Store instructions.
- Context synchronization.

The following subsections describe the Armv8 memory barrier instructions:

- *Instruction Synchronization Barrier (ISB)* on page E2-3824.
- *Data Memory Barrier (DMB)* on page E2-3824.
- *Data Synchronization Barrier (DSB)* on page E2-3824.
- *Speculation Barrier (SB)* on page E2-3825.
- *Consumption of Speculative Data Barrier (CSDB)* on page E2-3825.
- *Speculative Store Bypass Barrier (SSBB)* on page E2-3826.
- *Speculative Store Bypass Barrier (PSSBB)* on page E2-3826.
- *Trace Synchronization Barrier (TSB CSYNC)* on page E2-3826.
- *Shareability and access limitations on the data barrier operations* on page E2-3827.
- *Load-Acquire, Store-Release* on page E2-3828.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

The `DMB` and `DSB` memory barriers affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

AArch32 state also supports the legacy barrier instructions CP15DMB, CP15DSB, and CP15ISB. These instructions are executed as `MCR`s using the appropriate encoding, and are accessible from EL0. However, for performance reasons Arm deprecates any use of these operations, and strongly recommends that software uses the `DMB`, `DSB`, and `ISB` instructions described in this section instead. Optionally, an implementation can support a CP15BEN control that supervisory software can use to disable use of these instructions, meaning the corresponding `MCR` encodings are UNDEFINED. When the CP15BEN control is supported, setting one of the following CP15BEN fields to 0 makes execution of CP15DMB, CP15DSB, and CP15ISB UNDEFINED:

- SCTLR_EL1.CP15BEN, for execution of these instructions at EL0 using AArch32 when EL1 is using AArch64.
- SCTLR.CP15BEN, for execution of these instructions at EL0 or EL1 when EL1 is using AArch32.
- HSCTLR.CP15BEN, for execution of these instructions at EL2 when EL2 is using AArch32.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Instruction Synchronization Barrier (ISB)

An `ISB` instruction ensures that all instructions that come after the `ISB` instruction in program order are fetched from the cache or memory after the `ISB` instruction has completed. Using an `ISB` ensures that the effects of context-changing operations executed before the `ISB` are visible to the instructions fetched after the `ISB` instruction. Examples of context-changing operations that require the insertion of an `ISB` instruction to ensure the effects of the operation are visible to instructions fetched after the `ISB` instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the `ISB` instruction only take effect after the `ISB` has been executed.

The pseudocode function for the operation of an `ISB` is `InstructionSynchronizationBarrier()`.

See also *Memory barriers* on page G4-5717.

Data Memory Barrier (DMB)

The DMB instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The DMB instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the DMB is covered formally in the *Definition of the Armv8 memory model* on page E2-3814 and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB that appear in program order before the DMB and those which originate from a different PE, to the extent required by the DMB options, which have been Observed-by the PE before the DMB is executed, are Observed-by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB are Observed-by that PE.

The use of a `DMB` creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The pseudocode function for the operation of a `DMB` is `DataMemoryBarrier()`.

Data Synchronization Barrier (DSB)

A DSB is a memory barrier that ensures that memory accesses that occur before the DSB have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a `DSB` at EL2 ensures that any memory accesses caused by speculative translation table walks from the Non-secure PL1&0 translation regime have been observed.

For more information, see *Use of out-of-context translation regimes* on page G5-5726.

A `DSB` executed by a PE, PEe, completes when all of the following apply:

- All explicit memory accesses of the required access types appearing in program order before the DSB are complete for the set of observers in the required shareability domain.
- If the required access types of the `DSB` is reads and writes, then all cache maintenance instructions, all TLB maintenance instructions, and all `PSB CYNC` instructions issued by PEe before the `DSB` are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes, other than:

- Being fetched from memory and decoded.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Reading the general-purpose, SIMD and floating-point, Special-purpose, or System registers that are directly or indirectly read without causing side-effects.

The pseudocode function for the operation of a `DSB` is `DataSynchronizationBarrier()`.

See also *Memory barrier instructions* on page G4-5714 and *Memory barriers* on page G4-5717.

Speculation Barrier (SB)

An SB is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier:

- Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be performed when predicting that a instruction that could generate an exception does not generate an exception.

Speculative execution of an `SB` instruction:

- Cannot be as a result of control flow speculation.
- Cannot be as a result of data value speculation.
- Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An `SB` instruction can complete when:

- It is known that it is not speculative.
- All the predicted data values generated by instructions appearing in program order before the `SB` instruction have their predicted values confirmed.

Note

The `SB` instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted `SB` instruction.

Consumption of Speculative Data Barrier (CSDB)

The CSDB instruction is a memory barrier instruction that controls speculative execution and data value prediction. This includes:

- Data value predictions of any instructions.
- `PSTATE.{N,Z,C,V}` predictions of any instructions other than conditional branch instructions appearing in program order before the `CSDB` that have not been architecturally resolved.
- Predictions of SVE prediction state for any SVE instructions.

For purposes of the definition of CSDB, `PSTATE.{N,Z,C,V}` is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or `PSTATE.{N,Z,C,V}` predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Speculative Store Bypass Barrier (SSBB)

The SSBB is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the `SSBB`, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the `SSBB`.
- When a load to a location appears in program order before the `SSBB`, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the `SSBB`.

Physical Speculative Store Bypass Barrier (PSSBB)

The PSSBB is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the `PSSBB`, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the `PSSBB`.
- When a load to a location appears in program order before the `PSSBB`, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the `PSSBB`.

Trace Synchronization Barrier (TSB CSYNC)

The `TSB CSYNC` is a memory barrier instruction that preserves the relative order of memory accesses to System registers due to trace operations and other memory accesses to the same registers.

A trace operation is an operation of the PE Trace Unit generating trace for an instruction when ARMv8.4-Trace is implemented and enabled.

A `TSB CSYNC` is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more context synchronization events are required to ensure that `TSB CSYNC` is executed in the necessary order.

If trace is generated between a context synchronization event and a `TSB CSYNC` operation, these trace operations may be reordered with respect to the `TSB CSYNC` operation, and therefore may not be synchronized.

The following situations are synchronized using a `TSB CSYNC`:

- A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation A, if all of the following are true:
  - A is executed in program order before a context synchronization event C.
  - C is in program order before a `TSB CSYNC` operation T.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— B is executed in program order after T.

- A direct read B of a System register is ordered after an indirect write to the same register by a trace operation if all the following are true:
  — A is executed in program order before a context synchronization event C1.
  — C1 is in program order before `TSB CSYNC` operation T.
  — T is executed in program order before a second context synchronization event C2.
  — B is executed in program order after C2.

A `TSB CSYNC` is not needed when a direct write to a System register is ordered before an indirect read or indirect write of the same register by a trace operation if a context synchronization event is executed in program order between them.

The pseudocode function for the operation of a `TSB CSYNC` is `TraceSynchronizationBarrier()`.

Shareability and access limitations on the data barrier operations

The `DMB` and `DSB` instructions can each take an optional limitation argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  — Full system.
  — Outer Shareable.
  — Inner Shareable.
  — Non-shareable.
- The accesses for which the instruction operates. This is one of:
  — Read and write accesses, both before and after the barrier instruction.
  — Write accesses only, before and after the barrier instruction.
  — Read accesses before the barrier instruction, and read and write accesses after the barrier instruction.

Note

This form of a `DMB` or `DSB` instruction can be described as a Load-Load/Store barrier.

For more information on whether an access is before or after a barrier instruction, see *Data Memory Barrier (DMB)* on page E2-3824 or *Data Synchronization Barrier (DSB)* on page E2-3824.

Table E2-1 shows how these options are encoded in the `<option>` field of the instruction.

Table E2-1 Encoding of the `DMB` and `DSB` `<option>` parameter

Accesses		Shareability domain			
Before the barrier	**After the barrier**	**Full system**	**Outer Shareable**	**Inner Shareable**	**Non-shareable**
Reads and writes	Reads and writes	`SY`	`OSH`	`ISH`	`NSH`
Writes	Writes	`ST`	`OSHST`	`ISHST`	`NSHST`
Reads	Reads and writes	`LD`	`OSHLD`	`ISHLD`	`NSHLD`

If no `<option>` is specified then the instruction operates for read and write accesses, over the full system, meaning the operation is the same as for the `SY` option. See the instruction descriptions for more information:

- *DMB* on page F5-4180.
- *DSB* on page F5-4183.

Note

`ISB` also supports an optional limitation argument that can only contain one value that corresponds to full system operation, see *ISB* on page F5-4203.

Load-Acquire, Store-Release

Armv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores.

The full definition of the Load-Acquire instruction is covered formally in the *Definition of the Armv8 memory model* on page E2-3814 and this introduction to the Load-Acquire instruction is not intended to contradict that section.

The basic principle of a Load-Acquire instruction is to introduce order between the memory access generated by the Load-Acquire instruction and the memory accesses appearing in program order after the Load-Acquire instruction, such that the memory access generated by the Load-Acquire instruction is Observed-by each PE, to the extent that that PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire instruction are Observed-by that PE, to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the *Definition of the Armv8 memory model* on page E2-3814 and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the memory accesses generated by the PEe executing the Store-Release instruction, together with those which originate from a different PE, to the extent that the PEe is required to observe them coherently, Observed-by the PEe before executing the Store-release.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

In addition, the use of a Load-Acquire or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral coherence order.

Load-Acquire and Store-Release, other than `LDAEXD` and `STLEXD`, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

`LDAEXD` and `STLEXD` access two data elements. The address supplied to the instructions must be doubleword aligned, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit `DMB` memory barrier instruction.

Table E2-2 summarizes the Load-Acquire/Store-release instructions.

Table E2-2 Load-Acquire/Store-Release instructions

Data type	Load-Acquire	Store-Release	Load-Acquire Exclusive	Store-Release Exclusive
32-bit word	`LDA`	`STL`	`LDAEX`	`STLEX`
16-bit halfword	`LDAH`	`STLH`	`LDAEXH`	`STLEXH`
8-bit byte	`LDAB`	`STLB`	`LDAEXB`	`STLEXB`
64-bit doubleword	-	-	`LDAEXD`	`STLEXD`

E2.4 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. Armv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- *Introduction to caches*.
- *Memory hierarchy*.
- *Implication of caches for the application programmer* on page E2-3830.
- *Preloading caches* on page E2-3832.

E2.4.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access and take account of two principles of locality:

Spatial locality

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. Armv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

E2.4.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an Armv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure E2-1 on page E2-3830 shows an example of such a system in an Armv8-A system that supports virtual addressing.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

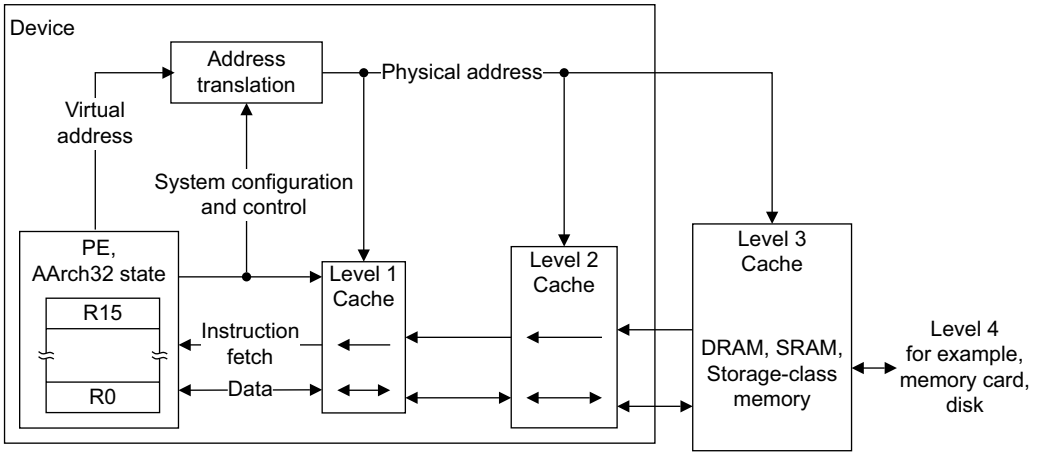

Figure E2-1 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the PE, as shown in Figure E2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU) and Point of Coherency (PoC). For more information, including the definitions of PoU and PoC, see *About cache maintenance in AArch32 state* on page G4-5693.

Note

Armv8 ARMv8.2-DCPoP adds architectural support for an additional conceptual point, Point of Persistence, but this support is provided only in AArch64 state. For more information see *About cache maintenance in AArch64 state* on page D4-2478.

The Cacheability and Shareability memory attributes

Cacheability and Shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

Shareability This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about the Cacheability and Shareability attributes see *Memory types and attributes* on page E2-3840.

E2.4.3 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  - Not enabling caches in the system.
- By using system calls to functions using cache maintenance instructions that execute at a higher Exception level.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see *Non-shareable Normal memory* on page E2-3842 and *Shareable, Inner Shareable, and Outer Shareable Normal memory* on page E2-3841.

Note

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last *Context synchronization event* on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The Arm architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using *Context synchronization event*s and cache maintenance instructions. These can only be accessed from an Exception level that is higher than EL0, and therefore require a system call, see *Exception-generating and exception-handling instructions* on page F1-3885. The following code sequence can be used for this purpose:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
       STR Rt, [Rn]
       DCCMVAU Rn          ; Clean data cache by MVA to point of unification (PoU)
       DSB                 ; Ensure visibility of the data cleaned from cache
       ICIMVAU Rn          ; Invalidate instruction cache by MVA to PoU
       BPIMVA  Rn          ; Invalidate branch predictor by MVA to PoU
       DSB                 ; Ensure completion of the invalidations
       ISB                 ; Synchronize the fetched instruction stream
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A write has been made coherent with an instruction fetch of a shareability domain when:

CTR.{DIC, IDC} == {0, 0}

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} == {1, 0}

The location written to has been cleaned to the *Point of unification (PoU)* from the data cache, and that clean is complete for the shareability domain.

CTR.{DIC, IDC} == {0, 1}

The write is complete for the shareability domain. Subsequently the location has been invalidated to the *Point of unification (PoU)* from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} == {1, 1}

The write is complete for the shareability domain.

Note

- For accesses that are Non-cacheable or Write-Through, the clean data cache instruction is not required. For accesses that are Non-cacheable, the invalidate instruction cache is not required, because in AArch32 state these accesses are not permitted to be held in an instruction cache.
- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The Armv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See *Concurrent modification and execution of instructions* on page E2-3812.

E2.4.4 Preloading caches

The Arm architecture provides the memory system hints `PLD` (Preload Data), `PLDW` (Preload Data With Intent To Write) and `PLI` (Preload Instruction) that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as `NOP`s without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is reported using an SError interrupt and taken using an asynchronous Data Abort exception. For more information, see *Data Abort exception* on page G1-5547.

A `PLD`, `PLDW`, or `PLI` instruction can only cause allocation to software-visible caching structures such caches or TLBs for memory locations that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

A `PLD`, `PLDW`, or `PLI` instruction can access any memory location in Normal memory that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

In each case, the entire list applies to each of PLD, PLDW, and PLI.

A PLD, PLDW, or PLI instruction is guaranteed not to access any type of Device memory.

A PLI instruction must not perform any access that cannot be performed by a speculative instruction fetch by the processor. Therefore in a VMSA implementation, if all associated MMUs are disabled, a PLI instruction cannot access any memory location that cannot be accessed by instruction fetches.

The pseudocode enumeration PrefetchHint defines the prefetch hint types.

The Hint_Prefetch() pseudocode function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

For more information on PLD, PLI, and PLDW, see:

- *PLD, PLDW (immediate)* on page F5-4400.
- *PLD (literal)* on page F5-4402.
- *PLD, PLDW (register)* on page F5-4404.
- *PLI (immediate, literal)* on page F5-4406.
- *PLI (register)* on page F5-4409.

E2.5 Alignment support

This section describes alignment support. It contains the following subsections:

- *Instruction alignment*.
- *Unaligned data access*.
- *Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE* on page E2-3835.
- *Unaligned data access restrictions* on page E2-3835.
- *Generation of Alignment faults by Load/store multiple accesses to Device memory* on page E2-3835.

For more information about Alignment faults see *Alignment faults* on page G5-5818.

E2.5.1 Instruction alignment

A32 instructions are word-aligned.

T32 instructions are halfword-aligned.

E2.5.2 Unaligned data access

An Armv8 implementation must support unaligned data accesses to Normal memory by some load and store instructions. As Table E2-3 shows, software can control whether a misaligned access to Normal memory by one of these instructions causes an Alignment fault Data Abort exception:

- By setting SCTLR.A, for unaligned accesses from any mode other than Hyp mode.
- By setting HSCTLR.A, for unaligned accesses from Hyp mode.

Table E2-3 Alignment requirements of load/store instructions

Instructions	Alignment check	Result if check fails when: SCTLR.A or HSCTLR.A is 0	Result if check fails when: SCTLR.A or HSCTLR.A is 1
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB	None	-	-
LDRH, LDRHT, LDRSH, LDRSHT, STRH, STRHT, TBH	Halfword	Unaligned access	Alignment fault
LDREXH, STREXH, LDAH, STLH, LDAEXH, STLEXH	Halfword	Alignment fault	Alignment fault
LDR, LDRT, STR, STRT PUSH, encodings T3 and A2 only POP, encodings T3 and A2 only	Word	Unaligned access	Alignment fault
LDREX, STREX, LDA, STL, LDAEX, STLEX	Word	Alignment fault	Alignment fault
LDREXD, STREXD, LDAEXD, STLEXD	Doubleword	Alignment fault	Alignment fault
All forms of LDM and STM, LDRD, RFE, SRS, STRD	Word	Alignment fault	Alignment fault
LDC, STC	Word	Alignment fault	Alignment fault
VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR	Word	Alignment fault	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with standard alignment	Element size	Unaligned access	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with :<align> specified[a]	As specified by :<align>	Alignment fault	Alignment fault

a. Previous versions of this manual used @<align> to specify alignment. Both forms are supported, see Chapter F6 *T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions* for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Any unaligned access to any type of Device memory generates an Alignment fault, see *Alignment faults* on page G5-5818.

E2.5.3 Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE

Any load instruction that is not faulted by the alignment restrictions shown in Table E2-3 on page E2-3834 and that loads the PC has CONSTRAINED UNPREDICTABLE behavior if the address it loads from is not word-aligned, see *Loads and Stores to unaligned locations* on page K1-7608. This overrules any permitted Load/Store behavior shown in Table E2-3 on page E2-3834.

E2.5.4 Unaligned data access restrictions

The following points apply to unaligned data accesses in Armv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see *Atomicity in the Arm architecture* on page E2-3810.
- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

E2.5.5 Generation of Alignment faults by Load/store multiple accesses to Device memory

When ARMv8.2-LSMAOC is implemented and the value of the applicable nTLSMD field is 0, any memory access by an AArch32 Load Multiple or Store Multiple instruction to an address that the stage 1 translation assigns as Device-nGRE, Device-nGnRE, or Device-nGnRnE generates an Alignment fault.

The applicable nTLSMD field is the field in the SCTLR_EL1, SCTLR_EL2, HSCTLR, or SCTLR register that applies to the Exception level and Security state at which the `LDM` or `STM` instruction is executed.

E2.6 Endian support

General description of endianness in the Arm architecture describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness*.
- *Data endianness* on page E2-3837.
- *Endianness of memory-mapped peripherals* on page E2-3838.

E2.6.1 General description of endianness in the Arm architecture

This section only describes memory addressing and the effects of endianness for data elements up to doubleword of 64 bits. However, this description can be extended to apply to larger data elements.

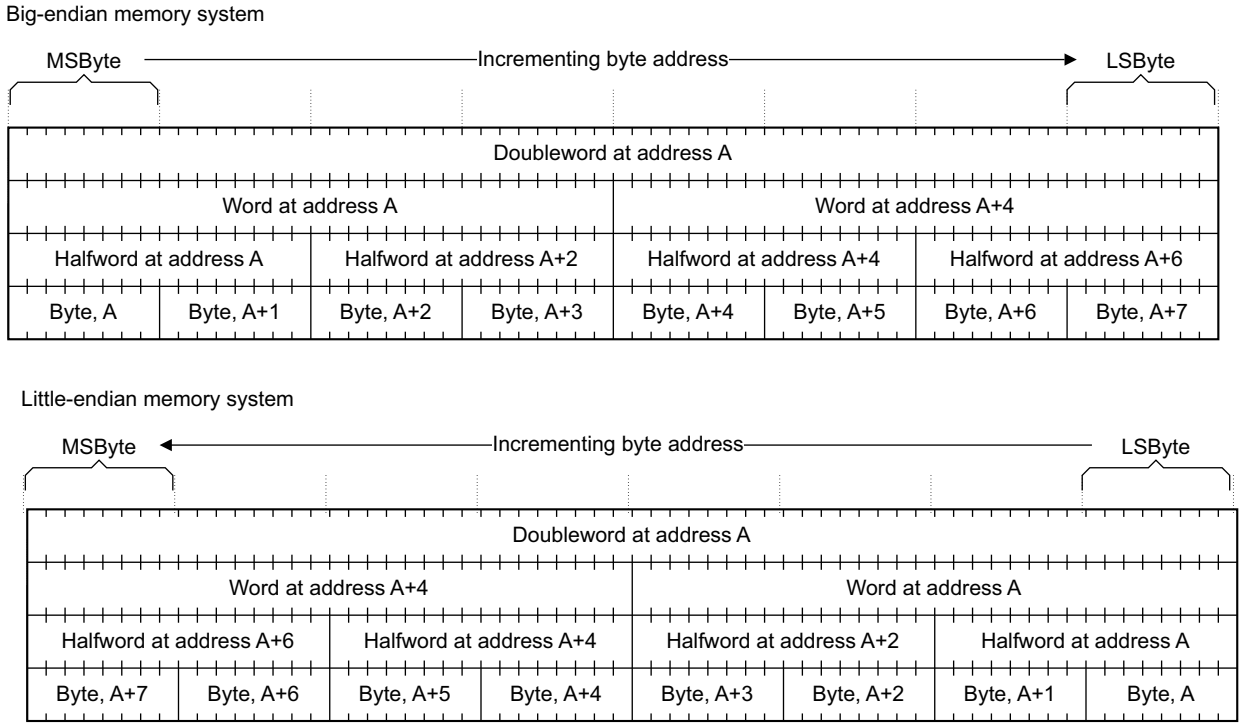
For an address A, Figure E2-2 shows, for big-endian and little-endian memory systems, the relationship between:

- The doubleword at address A.
- The words at addresses A and A+4.
- The halfwords at addresses A, A+2, A+4, and A+6.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.

The terms in Figure E2-2 have the following definitions:

MSByte Most-significant byte.

LSByte Least-significant byte.



In this figure, *Byte, A+1* is an abbreviation for *Byte at address A+1*

Figure E2-2 Endianness relationships in AArch32 state

E2.6.2 Instruction endianness

In Armv8-A, the mapping of instruction memory is always little-endian.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.6.3 Data endianness

The size of the data value that is loaded or stored is the size that is used for the purpose of endian conversion for floating-point, Advanced SIMD, and general-purpose register loads and stores.

Table E2-4 shows the element sizes of all the load/store instructions, for all instruction sets.

Table E2-4 Element size of load/store instructions

Instructions	Element size
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB	Byte
LDRH, LDREXH, LDRHT, LDRSH, LDRSHT, STRH, STREXH, STRHT, TBH	Halfword
LDR, LDRT, LDREX, STR, STRT, STREX	Word
LDRD, LDREXD, STRD, STREXD	Word
All forms of LDM, PUSH, POP, RFE, SRS, all forms of STM,	Word
LDC, STC	Word
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 32-bit Si registers	Word
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 64-bit Di registers	Doubleword
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4	Element size of the Advanced SIMD access

CPSR.E determines the data endianness.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for Advanced SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for Advanced SIMD element and data structure loads and stores. For more information see *Endianness in Advanced SIMD* on page E2-3838.

Instructions to reverse bytes in registers

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table E2-5 shows the instructions that provide this functionality in the A32 and T32 instruction sets.

Table E2-5 Byte reversal instructions

Function	T32 / A32 Instruction	Notes
Reverse bytes in whole register	REV	For use with general purpose registers.
Reverse bytes in 16-bit halfwords	REV16	For use with general purpose registers.
Reverse bytes in halfword and sign-extend	REVSH	For use with general purpose registers.
Reverse elements in doublewords, vector	VREV64	For use with registers in the SIMD and floating-point register file
Reverse elements in words, vector	VREV32	For use with registers in the SIMD and floating-point register file
Reverse elements in halfwords, vector	VREV16	For use with registers in the SIMD and floating-point register file

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Endianness in Advanced SIMD

Advanced SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the PE to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the A32 or T32 instruction:

```
VLD1.16 {D0}, [R1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure E2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

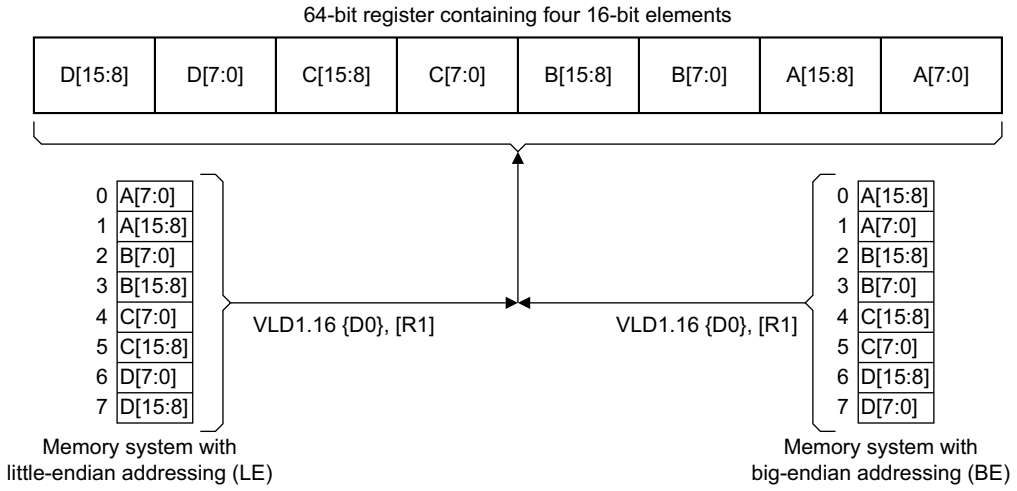


Figure E2-3 Advanced SIMD byte order example for AArch32 state

For information about the alignment of Advanced SIMD instructions see *Alignment support* on page E2-3834.

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in Chapter J1 *Armv8 Pseudocode*.

E2.6.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a cross-trigger interface, see Chapter H8 *About the External Debug Registers*.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see Chapter I2 *System Level Implementation of the Generic Timer*.
- A memory-mapped register interface to the Performance Monitors, see Chapter I3 *Recommended External Interface to the Performance Monitors*.
- A memory-mapped register interface to the Activity Monitors, see Chapter I4 *Recommended External Interface to the Activity Monitors*.
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.*

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The memory-mapped register interface to an Arm trace component. See, for example, the *ARM® Embedded Trace Macrocell Architecture Specification, ETMv4.*

E2.7 Memory types and attributes

In Armv8 the ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- *Normal memory*.
- *Device memory* on page E2-3844.
- *Memory access restrictions* on page E2-3849.

E2.7.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.
- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.
- Writes to a memory location with the Normal memory attribute that is Non-cacheable must reach the endpoint for that location in the memory system in finite time.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Normal memory* on page E2-3844.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- An instruction that generates a sequence of accesses as described in *Atomicity in the Arm architecture* on page E2-3810 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- *Shareable Normal memory* on page E2-3841.
- *Non-shareable Normal memory* on page E2-3842.
- *Cacheability attributes for Normal memory* on page E2-3842.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is defined as one of:

- Inner Shareable.
- Outer Shareable.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see *Synchronization and coherency issues between data and instruction accesses* on page E2-3831.

Note

- System designers can use the Shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the Shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different PEs.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The details of the use of the Shareability attributes are system-specific. Example E2-1 shows how they might be used.

Example E2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different Shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same Shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable Shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable Shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information see *Cacheability, cache allocation hints, and cache transient hints* on page G4-5690.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location.
- For other cases see *Mismatched memory attributes* on page E2-3850.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the Shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

Example E2-2, Example E2-3 on page E2-3844, and Example E2-4 on page E2-3844 describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Note

- L1 cache is the level closest to the PE, see *Memory hierarchy* on page E2-3829.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the Shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example E2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
- The Outer cacheability attribute applied to L3 cache.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example E2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example E2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 cache.
- The Outer cacheability attribute applied to L2 and L3 cache.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more registers from the SIMD and floating-point register file from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

E2.7.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Armv8 Device memory are:

Gathering Identified as G or nG, see *Gathering* on page E2-3846.

Reordering Identified as R or nR, see *Reordering* on page E2-3847.

Early Write Acknowledgement

Identified as E or nE, see *Early Write Acknowledgement* on page E2-3848.

The Armv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early write acknowledgement.

Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.

Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.

Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

The Device-nGRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.

The Device-GRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.
- Earlier versions of the Arm architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  An exception to this applies:

  - Reads generated by the Advanced SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

  Note

  - An instruction that generates a sequence of accesses as described in *Atomicity in the Arm architecture on page E2-3810* might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.
  - Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.
- If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

  Note

  In the Non-secure PL1&0 translation regime in systems where HCR.TGE==1 and HCR.DC==0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes the value of HSR.ISS.[24] to be 0.

- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

  Note

  This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

See also *Memory access restrictions* on page E2-3849.

The memory types for Translation table walks cannot be defined as any Device memory type within the TCR. For the Non-secure EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR.PTW bit is 1, a stage 2 permission fault is generated if a first stage translation table walk is made to any Device memory type.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Device memory* on page E2-3848.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a `DMB` or `DSB` barrier that affects both of the accesses.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.
- The Arm architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the `DMB` instruction.
- The Arm architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

An additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Early Write Acknowledgement

In the Device memory attribute:

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.

For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgement of a write comes from the endpoint, assigning the No Early Write Acknowledgement attribute to a Device memory location guarantees that:

- Only the endpoint of the write access returns a write acknowledgement of the access.
- No earlier point in the memory system returns a write acknowledgement.

This means that a `DSB` barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system.

Peripherals are an example of system endpoints that require that the acknowledgement of a write comes from the endpoint.

Note

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgement is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
- The areas of the physical memory map for which write acknowledgement from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgement from the endpoint.
- Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgement from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgement from the endpoint.
- For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a `DSB` instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgement from the endpoint.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load and store instructions.

For all instructions that load or store one or more registers from the SIMD and floating-point register file there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load and store instructions.

For an `LDRD`, `STRD`, or `LDM` instruction with a register list that includes the PC, or an `STM` instruction with a register list that includes the PC, the order in which the registers are accessed is not defined by the architecture.

For a load or store of an Advanced SIMD element or structure, the order in which the registers are accessed is not defined by the architecture.

For a `VLDM` and `VSTM` instruction with a register list that does not include the PC, all registers are accessed in ascending address order for accesses to Device memory with the non-Reordering attribute.

For a `LDM` or `STM` instruction with a register list that does not include the PC:

- When ARMv8.2-LSMAOC is not implemented, and when ARMv8.2-LSMAOC is implemented and the value of the applicable LSMAOE field is 1, all registers are accessed in ascending address order for accesses to Device memory with the non-Reordering attribute.
- When ARMv8.2-LSMAOC is implemented and the value of the applicable LSMAOE field is 0, no memory accesses are required to be ordered.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When ARMv8.2-LSMAOC is implemented and the value of the applicable nTLSMD field is 0, any memory access to an address that the stage 1 translation assigns as Device-nGRE, Device-nGnRE, or Device-nGnRnE generates an Alignment fault.

The applicable LSMAOE or nTLSMD field is the field in the SCTLR_EL1, SCTLR_EL2, HSCTLR, or SCTLR register that applies to the Exception level and Security state at which the `LDM` or `STM` instruction is executed.

Armv8.2 deprecates software relying on accesses to Device memory made by a single `LDM` or `STM` instruction not being reordered.

E2.7.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For accesses to any two bytes, *p* and *q*, that are generated by the same instruction:
  - The bytes *p* and *q* must have the same memory type and Shareability attributes. otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an `LDC`, `LDM`, `LDRD` `STC`, `STM` `or` `STRD` instruction, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes *p* and *q*.

  For the permitted CONSTRAINED UNPREDICTABLE behavior, see *Crossing a page boundary with different memory types or Shareability attributes* on page K1-7617.
- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross a 4KB address boundary then behavior is CONSTRAINED UNPREDICTABLE and *Crossing a 4KB boundary with a Device access* on page K1-7617 describes the permitted behaviors.

  Note
  - The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.
  - This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.
  - Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.

Non-Confidential

E2.8 Mismatched memory attributes

In the Armv8 architecture mismatched memory attributes are controlled by privileged software. For more information, see Chapter G5 *The AArch32 Virtual Memory System Architecture*.

Physical memory Locations are accessed with *mismatched attributes* if all accesses to the Location do not use a common definition of all of the following attributes of that Location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

Note

In this document, the terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory Location is accessed with mismatched attributes the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
  - A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
  - Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory Location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of speculative read accesses.
- Prohibition on Gathering.
- Prohibition on Re-ordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. If the only memory type mismatch associated with a memory Location across all users of the memory Location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.
2. Any agent that reads that memory Location using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
   - All writes are performed to an alias of the memory Location that uses the same definition of the Memory type, Shareability and Cacheability attributes.
   - Either:
     - In the Non-secure PL1&0 translation regime, HCR2.MIOCNCE has a value of 0.
     - All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Either:
  - All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable.
  - All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.

3. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
   - Any Device memory type.
   - Normal Inner Non-cacheable, Outer Non-cacheable memory.

   In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   - Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
   - Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting `DMB` barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory Location all assign the same Shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a Shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
   - Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
   - After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory.
   - Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
   - Executing a `DMB` barrier instruction, with scope that applies to the common Shareability of the accesses, between any accesses to the same cacheable Location that use different attributes.

   Note

   In AArch32 state, cache maintenance instructions can only be accessed from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see *Exception-generating and exception-handling instructions* on page F1-3885. For information about the AArch32 cache maintenance instructions, see *AArch32 cache and branch predictor support* on page G4-5687.

   In all cases:
   - Location refers to any byte within the current coherency granule.
   - A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   - In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see *Ordering of cache and branch predictor maintenance instructions* on page G4-5705.

Non-Confidential

Note

With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different Shareability attributes, then ordering and coherency are guaranteed only if:
   - Each PE that accesses the Location with a cacheable attribute performs a clean and invalidate of the Location before and after accessing that Location.
   - A `DMB` barrier with scope that covers the full Shareability of the accesses is placed between any accesses to the same memory Location that use different attributes.

   Note

   The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.

E2.9 Synchronization and semaphores

Armv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

Note

Use of the Armv8 synchronization primitives scales for multiprocessing system designs.

Table E2-6 shows the synchronization primitives and the associated CLREX instruction.

Table E2-6 Synchronization primitives and associated instruction, T32 and A32 instruction sets

Transaction size	Additional semantics	Load-Exclusive[a]	Store-Exclusive[a]	Other[a]
Byte	-	LDREXB	STREXB	-
	Load-Acquire/Store-Release	LDAEXB	STLEXB	-
Halfword	-	LDREXH	STREXH	-
	Load-Acquire/Store-Release	LDAEXH	STLEXH	-
Word	-	LDREX	STREX	-
	Load-Acquire/Store-Release	LDAEX	STLEX	-
Doubleword	-	LDREXD	STREXD	-
	Load-Acquire/Store-Release	LDAEXD	STLEXD	-
None	Clear-Exclusive	-	-	CLREX

a. Instruction in the T32 and A32 instruction sets.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address *x* is:

- The Load-Exclusive instruction reads a value from memory address *x*.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address *x* only if no other observer, process, or thread has performed a more recent store to address *x*. The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see *Marking and the size of the marked memory block* on page E2-3859. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- *Exclusive access instructions and Non-shareable memory locations* on page E2-3854.
- *Exclusive access instructions and shareable memory locations* on page E2-3855.

E2.9.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the Shareability attribute is Non-shareable, the exclusive access instructions rely on a *local Exclusives monitor*, or *local monitor*, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is *set*.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is *clear*.

The Store-Exclusive instruction defines the register to which the status value is returned.

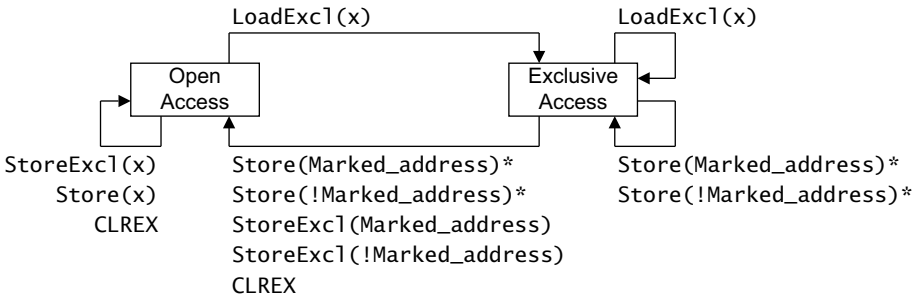
When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure E2-4 on page E2-3855 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: `LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any other store instruction.

Any `LoadExcl` operation updates the marked address to the most significant bits of the address x used for the operation.

Figure E2-4 Local monitor state machine diagram

For more information about marking see *Marking and the size of the marked memory block* on page E2-3859.

Note

For the local monitor state machine, as shown in Figure E2-4:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure E2-4.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure E2-4.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure E2-4 must not indefinitely delay forward progress of execution.

E2.9.2 Exclusive access instructions and shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For shareable memory locations, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory locations* on page E2-3854, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

  The local monitor can ignore accesses from other PEs in the system.
- A *global monitor* that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the Shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold at least one marked block.
  - Maintains a state machine for each marked block it can hold.

  Note

  For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is CONSTRAINED UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page E2-3859.

Note

The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

Note

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault status code of:
  - DFSR.STATUS = `0b110101` when using the Long-descriptor translation table format. The fault can also be reported in the HSR.ISS[5:0] field for exceptions to Hyp mode.
  - DFSR.FS = `0b10101` when using the Short-descriptor translation table format.

  If the IMPLEMENTATION DEFINED MMU fault is generated for the Non-secure PL1&0 translation regime then:
  - If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
  - Otherwise, the fault is a second stage fault and the exception is taken to EL2.

  The priority of this fault is IMPLEMENTATION DEFINED.
- The instruction is treated as a `NOP`.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an Arm PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

Operation of the global Exclusives monitor

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

Note

The global monitor only supports a single outstanding exclusive access to shareable memory for each PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means it responds to:

- Accesses generated by PE(n).
- Accesses generated by the other observers in the Shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

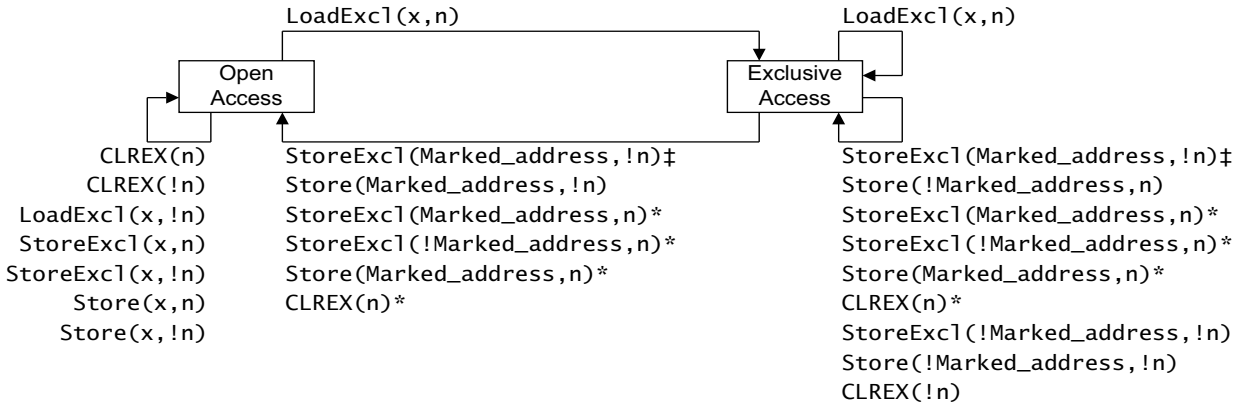
A global monitor:

- In the Exclusive Access state is *set*.
- In the Open Access state is *clear*.

Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see *Wait For Event and Send Event* on page G1-5562.

Figure E2-5 shows the state machine for PE(n) in a global monitor.



‡StoreExcl(Marked_address,!n) clears the monitor only if the StoreExcl updates memory
Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure E2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking see *Marking and the size of the marked memory block* on page E2-3859.

Note

For the global monitor state machine, as shown in Figure E2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure E2-5 on page E2-3858 only shows how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a `CLREX` instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

E2.9.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the *Exclusives reservation granule*. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4 - 512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where *a* is 4.
- 512 words in an implementation where *a* is 11.

For example, in an implementation where *a* is 4, a successful `LDREXB` of address `0x341B4` defines a marked block using bits[47:4] of the address. This means that the four words of memory from `0x341B0` to `0x341BF` are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

E2.9.4 Context switch support

An exception return clears the local monitor. As a result, performing a `CLREX` instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

E2.9.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a `LDREX`/`STREX` pair or a `LDREXB`/`STREXB` pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following notes describe use of a Load-Exclusive/ Store-Exclusive instruction pair, `LoadExcl`/`StoreExcl`, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table E2-6 on page E2-3853. In this context, a `LoadExcl`/`StoreExcl` pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target VA of a `StoreExcl` is different from the VA of the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The `StoreExcl` either passes or fails, the status value returned by the `StoreExcl` is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

    Note

    This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with mismatched addresses, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with mismatched addresses.

  - The data at the address accessed by the `LoadExcl`, and at the address accessed by the `StoreExcl`, is UNKNOWN.

  This means software can rely on a `LoadExcl`/`StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a `StoreExcl` instruction is the same as the transaction size of the preceding `LoadExcl` instruction executed in that thread. If the transaction size of a `StoreExcl` instruction is different from the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

    Note

    This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with mismatched transaction sizes, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with mismatched transaction sizes.

  - The block of data of the size of the larger of the transaction sizes used by the `LoadExcl`/`StoreExcl` pair at the address accessed by the `LoadExcl`/`StoreExcl` pair, is UNKNOWN.

  This means software can rely on a `LoadExcl`/`StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` have the same transaction size.

- `LoadExcl`/`StoreExcl` loops are guaranteed to make forward progress only if, for any `LoadExcl`/`StoreExcl` loop within a single thread of execution, the software meets all of the following conditions:

  1 Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory accesses, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.

  2 Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:

  - There are no stores or `PLDW` instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.
  - There are no loads or preloads to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.
  - There are no direct or indirect System register writes, other than changes to the flag fields in the CPSR or FPSCR, caused by data processing or comparison instructions.
  - There are no direct or indirect address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
  - All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the `LoadExcl`/`StoreExcl` loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

— Performing stores to a PA covered by the Exclusives monitor.

— Prefetching with intent to write to a PA covered by the Exclusives monitor.

— Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.

— Executing instruction cache invalidate all instructions.

— Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.

- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.
- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.
- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.
- For the memory location accessed by a `LoadExcl`/`StoreExcl` pair, if the memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:

  — The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

  Note

  This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes.

  — The data at the address accessed by the `StoreExcl` is UNKNOWN.

  Note

  Another bullet point in this list covers the case where the memory attributes of a `LoadExcl`/`StoreExcl` pair differ as a result of using different VAs with different attributes that point to the same PA.

- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same Shareability domain as the PE executing the cache maintenance instruction, as determined by the Shareability domain of the address being maintained.

  Note

  Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

- If the mapping of the VA to PA is changed between the `LoadExcl` instruction and the `StoreExcl` instruction, and the change is performed using a break-before-make sequence as described in *Using break-before-make when updating translation table entries* on page G5-5794, if the `StoreExcl` is performed after another write

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

to the same PA as the `StoreExcl`, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the `StoreExcl` will not pass its monitor check.

Note

Arm expects that, in many implementations, either:

— The TLB invalidation will clear either the local or global monitor.

— The PA will be checked between the `LoadExcl` and `StoreExcl`.

- The Exclusive Access state for an address accessed by a PE can be lost as a result of a `PLDW` instruction to the same PA executed by another PE. This means that a very high rate of repeated `PLDW` accesses to a memory location might impede the forward progress of another PE.

Note

In the event of repeatedly-contending `LoadExcl`/`StoreExcl` instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

E2.9.6 Use of WFE and SEV instructions by spin-locks

Armv8 provides Wait For Event, Send Event, and Send Event Local instructions, `WFE`, `SEV`, `SEVL`, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in *Wait For Event and Send Event* on page G1-5562. However, in Armv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an `SEVL` instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an `SEV` instruction after clearing a spinlock.

Part F
The AArch32 Instruction Sets

Chapter F1
The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

- *Support for instructions in different versions of the Arm architecture* on page F1-3866.
- *Unified Assembler Language* on page F1-3867.
- *Branch instructions* on page F1-3869.
- *Data-processing instructions* on page F1-3870.
- *PSTATE and banked register access instructions* on page F1-3878.
- *Load/store instructions* on page F1-3879.
- *Load/store multiple instructions* on page F1-3882.

F1.1 Support for instructions in different versions of the Arm architecture

This manual describes the Arm AArch32 instruction sets, T32 and A32, for the Armv8 architecture. Therefore, it indicates how any options or extensions in the Armv8 architecture affect the available instructions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F1.2 Unified Assembler Language

This manual uses the Arm *Unified Assembler Language* (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier Arm assembly language mnemonics are still supported as synonyms, as described in the instruction details.

Note

Most earlier T32 assembly language mnemonics are *not* supported.

UAL includes *instruction selection* rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an `ADD R0, R1, R2` instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

F1.2.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, Arm recommends that:

- `IT` instructions are written before conditional instructions in the correct way for the T32 instruction set.
- When assembling to the A32 instruction set, assemblers check that any `IT` instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an `IT` instruction must be written with a condition. These conditions must match the conditions imposed by the `IT` instruction. For example, an `ITTEE EQ` instruction imposes the `EQ` condition on the first two following instructions, and the `NE` condition on the next two. Those four instructions must be written with `EQ`, `EQ`, `NE` and `NE` conditions respectively.

Some instructions cannot be made conditional by an `IT` instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a Condition code field cannot be made conditional by an `IT` instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding `IT` instruction, it is assembled using a branch instruction encoding that does not include a Condition code field.

Note

For performance reasons Armv8 deprecates many uses of `IT`, see *Partial deprecation of IT* on page F1-3884. As described in that section, an implementation can include ITD controls that disable those uses of `IT`, making them UNDEFINED.

F1.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the `PC` or `Align(PC, 4)` value of the instruction. The `PC` value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The `Align(PC, 4)` value of an instruction is its `PC` value ANDed with `0xFFFFFFFC` to force it to be word-aligned. There is no difference between the `PC` and `Align(PC, 4)` values for an A32 instruction, but there can be for a T32 instruction.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

2. Calculate the offset from the `PC` or `Align(PC, 4)` value of the instruction to the address of the labeled instruction or literal data item.

3. Assemble a *PC-relative* encoding of the instruction, that is, one that reads its `PC` or `Align(PC, 4)` value and adds the calculated offset to form the required address.

Note

For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- `B`, `BL`, and `BLX` (immediate). The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the `PC` value of the instruction to form the target address of the branch.
- `CBNZ` and `CBZ`. The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the `PC` value of the instruction to form the target address of the branch. They do not support backward branches.
- `LDR`, `LDRB`, `LDRD`, `LDRH`, `LDRSB`, `LDRSH`, `PLD`, `PLDW`, `PLI`, and `VLDR`. The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

  When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the `Align(PC, 4)` value of the instruction. Encodings that subtract 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

  There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by `[PC, #+/-<imm>]`, where:

  `+/-` Is `+` or omitted to specify that the immediate offset is to be added to the `Align(PC, 4)` value, or `-` if it is to be subtracted.

  `<imm>` Is the immediate offset.

  This alternative syntax makes it possible to assemble the encodings that subtract 0 from the `Align(PC, 4)` value, and to disassemble them to a syntax that can be re-assembled correctly.
- `ADR`. The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

  When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the `Align(PC, 4)` value of the instruction. The encoding that subtracts 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

  There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions `ADD <Rd>, PC, #<imm>` or subtractions `SUB <Rd>, PC, #<imm>`. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the `Align(PC, 4)` value, and to disassemble it to a syntax that can be re-assembled correctly.

Note

Arm recommends that where possible, software avoids using:

- The alternative syntax for the `ADR`, `LDC`, `LDR`, `LDRB`, `LDRD`, `LDRH`, `LDRSB`, `LDRSH`, `PLD`, `PLI`, `PLDW`, and `VLDR` instructions.
- The encodings of these instructions that subtract 0 from the `Align(PC, 4)` value.

F1.3 Branch instructions

Table F1-1 summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

Table F1-1 Branch instructions

Instruction	See	Range, T32	Range, A32
Branch to target address	*B* on page F5-4117	±16MB	±32MB
Compare and Branch on Nonzero, Compare and Branch on Zero	*CBNZ, CBZ* on page F5-4142	0-126 bytes	[a]
Call a subroutine Call a subroutine, change instruction set[b]	*BL, BLX (immediate)* on page F5-4135	±16MB ±16MB	±32MB ±32MB
Call a subroutine, optionally change instruction set	*BLX (register)* on page F5-4137	Any	Any
Branch to target address, change instruction set	*BX* on page F5-4139	Any	Any
Change to Jazelle state	*BXJ* on page F5-4141	-	-
Table Branch (byte offsets) Table Branch (halfword offsets)	*TBB, TBH* on page F5-4687	0-510 bytes 0-131070 bytes	[a]

a. These instructions do not exist in the A32 instruction set.

b. The range is determined by the instruction set of the `BLX` instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by `LDR`, `LDM` and data-processing instructions. For details see *Load/store instructions* on page F1-3879, *Load/store multiple instructions* on page F1-3882, *Standard data-processing instructions* on page F1-3870, and *Shift instructions* on page F1-3872.

In addition to the branch instructions shown in Table F1-1:

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see *Data-processing instructions* on page F1-3870.
- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see *Load/store instructions* on page F1-3879.

F1.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- *Standard data-processing instructions*.

  These instructions perform basic data-processing operations, and share a common format with some variations.
- *Shift instructions* on page F1-3872.
- *Multiply instructions* on page F1-3872.
- *Saturating instructions* on page F1-3874.
- *Saturating addition and subtraction instructions* on page F1-3874.
- *Packing and unpacking instructions* on page F1-3875.
- *Parallel addition and subtraction instructions* on page F1-3876.
- *Divide instructions* on page F1-3877.
- *Miscellaneous data-processing instructions* on page F1-3877.

For related Advanced SIMD and floating-point instructions see *Advanced SIMD data-processing instructions* on page F1-3891 and *Floating-point data-processing instructions* on page F1-3901.

F1.4.1 Standard data-processing instructions

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A *modified immediate constant* that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see *Modified immediate constants in T32 instructions* on page F2-3923 and *Modified immediate constants in A32 instructions* on page F2-3924.

If the second operand is another register, it can optionally be shifted in any of the following ways:

`LSL`	Logical Shift Left by 1-31 bits.
`LSR`	Logical Shift Right by 1-32 bits.
`ASR`	Arithmetic Shift Right by 1-32 bits.
`ROR`	Rotate Right by 1-31 bits.
`RRX`	Rotate Right with Extend. For details see *Shift and rotate operations* on page E1-3784.

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than `CMN`, `CMP`, `TEQ`, and `TST`, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the `ADD` and `MOV` instructions.

These instructions can optionally set the Condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

Table F1-2 on page F1-3871 summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in Chapter F2 *About the T32 and A32 Instruction Descriptions*, one section for each of the following:

- `INSTRUCTION` (immediate) where the second operand is a modified immediate constant.
- `INSTRUCTION` (register) where the second operand is a register, or a register shifted by a constant.
- `INSTRUCTION` (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.

Non-Confidential

Table F1-2 Standard data-processing instructions

Instruction	Mnemonic	Notes
Add with Carry	ADC	-
Add	ADD	T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Form PC-relative Address	ADR	First operand is the PC. Second operand is an immediate constant. T32 instruction set uses a zero-extended 12-bit immediate constant. Operation is an addition or a subtraction.
Bitwise AND	AND	-
Bitwise Bit Clear	BIC	-
Compare Negative	CMN	Sets flags. Like ADD but with no destination register.
Compare	CMP	Sets flags. Like SUB but with no destination register.
Bitwise Exclusive OR	EOR	-
Copy operand to destination	MOV	Has only one operand, with the same options as the second operand in most of these instructions. If the operand is a shifted register, the instruction is an LSL, LSR, ASR, or ROR instruction instead. For details see *Shift instructions* on page F1-3872. The T32 and A32 instruction sets permit use of a modified immediate constant or a zero-extended 16-bit immediate constant.
Bitwise NOT	MVN	Has only one operand, with the same options as the second operand in most of these instructions.
Bitwise OR NOT	ORN	Not available in the A32 instruction set.
Bitwise OR	ORR	-
Reverse Subtract	RSB	Subtracts first operand from second operand. This permits subtraction from constants and shifted registers.
Reverse Subtract with Carry	RSC	Not available in the T32 instruction set.
Subtract with Carry	SBC	-
Subtract	SUB	T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Test Equivalence	TEQ	Sets flags. Like EOR but with no destination register.
Test	TST	Sets flags. Like AND but with no destination register.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F1.4.2 Shift instructions

Table F1-3 lists the shift instructions in the T32 and A32 instruction sets.

Table F1-3 Shift instructions

Instruction	See
Arithmetic Shift Right	*ASR (immediate)* on page F5-4109 *ASR (register)* on page F5-4111 *ASRS (immediate)* on page F5-4113 *ASRS (register)* on page F5-4115
Logical Shift Left	*LSL (immediate)* on page F5-4315 *LSL (register)* on page F5-4317 *LSLS (immediate)* on page F5-4319 *LSLS (register)* on page F5-4321
Logical Shift Right	*LSR (immediate)* on page F5-4323 *LSR (register)* on page F5-4325 *LSRS (immediate)* on page F5-4327 *LSRS (register)* on page F5-4329
Rotate Right	*ROR (immediate)* on page F5-4453 *ROR (register)* on page F5-4455 *RORS (immediate)* on page F5-4457 *RORS (register)* on page F5-4459
Rotate Right with Extend	*RRX* on page F5-4461 *RRXS* on page F5-4463

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

F1.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- Table F1-4 summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.

  The least significant 32 bits of the result are used. More significant bits are discarded.
- Table F1-5 on page F1-3873 summarizes the signed multiply instructions.
- Table F1-6 on page F1-3873 summarizes the unsigned multiply instructions.

Table F1-4 General multiply instructions

Instruction	See	Operation (number of bits)
Multiply Accumulate	*MLA, MLAS* on page F5-4335	32 = 32 + 32 × 32
Multiply and Subtract	*MLS* on page F5-4337	32 = 32 – 32 × 32
Multiply	*MUL, MULS* on page F5-4373	32 = 32 × 32

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table F1-5 Signed multiply instructions

Instruction	See	Operation (number of bits)
Signed Multiply Accumulate (halfwords)	*SMLABB, SMLABT, SMLATB, SMLATT* on page F5-4522	32 = 32 + 16 × 16
Signed Multiply Accumulate Dual	*SMLAD, SMLADX* on page F5-4524	32 = 32 + 16 × 16 + 16 × 16
Signed Multiply Accumulate Long	*SMLAL, SMLALS* on page F5-4526	64 = 64 + 32 × 32
Signed Multiply Accumulate Long (halfwords)	*SMLALBB, SMLALBT, SMLALTB, SMLALTT* on page F5-4528	64 = 64 + 16 × 16
Signed Multiply Accumulate Long Dual	*SMLALD, SMLALDX* on page F5-4531	64 = 64 + 16 × 16 + 16 × 16
Signed Multiply Accumulate (word by halfword)	*SMLAWB, SMLAWT* on page F5-4533	32 = 32 + 32 × 16 [a]
Signed Multiply Subtract Dual	*SMLSD, SMLSDX* on page F5-4535	32 = 32 + 16 × 16 – 16 × 16
Signed Multiply Subtract Long Dual	*SMLSLD, SMLSLDX* on page F5-4537	64 = 64 + 16 × 16 – 16 × 16
Signed Most Significant Word Multiply Accumulate	*SMMLA, SMMLAR* on page F5-4539	32 = 32 + 32 × 32 [b]
Signed Most Significant Word Multiply Subtract	*SMMLS, SMMLSR* on page F5-4541	32 = 32 – 32 × 32 [b]
Signed Most Significant Word Multiply	*SMMUL, SMMULR* on page F5-4543	32 = 32 × 32 [b]
Signed Dual Multiply Add	*SMUAD, SMUADX* on page F5-4545	32 = 16 × 16 + 16 × 16
Signed Multiply (halfwords)	*SMULBB, SMULBT, SMULTB, SMULTT* on page F5-4547	32 = 16 × 16
Signed Multiply Long	*SMULL, SMULLS* on page F5-4549	64 = 32 × 32
Signed Multiply (word by halfword)	*SMULWB, SMULWT* on page F5-4551	32 = 32 × 16 [a]
Signed Dual Multiply Subtract	*SMUSD, SMUSDX* on page F5-4553	32 = 16 × 16 – 16 × 16

a. The most significant 32 bits of the 48-bit product are used. Less significant bits are discarded.
b. The most significant 32 bits of the 64-bit product are used. Less significant bits are discarded.

Table F1-6 Unsigned multiply instructions

Instruction	See	Operation (number of bits)
Unsigned Multiply Accumulate Accumulate Long	*UMAAL* on page F5-4727	64 = 32 + 32 + 32 × 32
Unsigned Multiply Accumulate Long	*UMLAL, UMLALS* on page F5-4729	64 = 64 + 32 × 32
Unsigned Multiply Long	*UMULL, UMULLS* on page F5-4731	64 = 32 × 32

Non-Confidential

F1.4.4 Saturating instructions

Table F1-7 lists the saturating instructions in the T32 and A32 instruction sets. For more information, see *Pseudocode description of saturation* on page E1-3785.

Table F1-7 Saturating instructions

Instruction	See	Operation
Signed Saturate	*SSAT* on page F5-4559	Saturates optionally shifted 32-bit value to selected range
Signed Saturate 16	*SSAT16* on page F5-4561	Saturates two 16-bit values to selected range
Unsigned Saturate	*USAT* on page F5-4749	Saturates optionally shifted 32-bit value to selected range
Unsigned Saturate 16	*USAT16* on page F5-4751	Saturates two 16-bit values to selected range

F1.4.5 Saturating addition and subtraction instructions

Table F1-8 lists the saturating addition and subtraction instructions in the T32 and A32 instruction sets. For more information, see *Pseudocode description of saturation* on page E1-3785.

Table F1-8 Saturating addition and subtraction instructions

Instruction	See	Operation
Saturating Add	*QADD* on page F5-4423	Add, saturating result to the 32-bit signed integer range
Saturating Subtract	*QSUB* on page F5-4436	Subtract, saturating result to the 32-bit signed integer range
Saturating Double and Add	*QADD* on page F5-4423	Doubles one value and adds a second value, saturating the doubling and the addition to the 32-bit signed integer range
Saturating Double and Subtract	*QDSUB* on page F5-4432	Doubles one value and subtracts the result from a second value, saturating the doubling and the subtraction to the 32-bit signed integer range

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F1.4.6 Packing and unpacking instructions

Table F1-9 lists the packing and unpacking instructions in the T32 and A32 instruction sets.

Table F1-9 Packing and unpacking instructions

Instruction	See	Operation
Pack Halfword	*PKHBT, PKHTB* on page F5-4397	Combine halfwords
Signed Extend and Add Byte	*SXTAB* on page F5-4675	Extend 8 bits to 32 and add
Signed Extend and Add Byte 16	*SXTAB16* on page F5-4677	Dual extend 8 bits to 16 and add
Signed Extend and Add Halfword	*SXTAH* on page F5-4679	Extend 16 bits to 32 and add
Signed Extend Byte	*SXTB* on page F5-4681	Extend 8 bits to 32
Signed Extend Byte 16	*SXTB16* on page F5-4683	Dual extend 8 bits to 16
Signed Extend Halfword	*SXTH* on page F5-4685	Extend 16 bits to 32
Unsigned Extend and Add Byte	*UXTAB* on page F5-4759	Extend 8 bits to 32 and add
Unsigned Extend and Add Byte 16	*UXTAB16* on page F5-4761	Dual extend 8 bits to 16 and add
Unsigned Extend and Add Halfword	*UXTAH* on page F5-4763	Extend 16 bits to 32 and add
Unsigned Extend Byte	*UXTB* on page F5-4765	Extend 8 bits to 32
Unsigned Extend Byte 16	*UXTB16* on page F5-4767	Dual extend 8 bits to 16
Unsigned Extend Halfword	*UXTH* on page F5-4769	Extend 16 bits to 32

F1.4.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the general-purpose registers.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

`S` Signed arithmetic modulo 2^8 or 2^{16}.

`Q` Signed saturating arithmetic.

`SH` Signed arithmetic, halving the results.

`U` Unsigned arithmetic modulo 2^8 or 2^{16}.

`UQ` Unsigned saturating arithmetic.

`UH` Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

`ADD16` Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.

`ASX` Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.

`SAX` Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.

`SUB16` Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.

`ADD8` Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.

`SUB8` Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as Table F1-10 shows.

See also *Advanced SIMD parallel addition and subtraction* on page F1-3892.

Table F1-10 Parallel addition and subtraction instructions

Main instruction	Signed	Saturating	Signed halving	Unsigned	Unsigned saturating	Unsigned halving
`ADD16`, add, two halfwords	`SADD16`	`QADD16`	`SHADD16`	`UADD16`	`UQADD16`	`UHADD16`
`ASX`, add and subtract with exchange	`SASX`	`QASX`	`SHASX`	`UASX`	`UQASX`	`UHASX`
`SAX`, subtract and add with exchange	`SSAX`	`QSAX`	`SHSAX`	`USAX`	`UQSAX`	`UHSAX`
`SUB16`, subtract, two halfwords	`SSUB16`	`QSUB16`	`SHSUB16`	`USUB16`	`UQSUB16`	`UHSUB16`
`ADD8`, add, four bytes	`SADD8`	`QADD8`	`SHADD8`	`UADD8`	`UQADD8`	`UHADD8`
`SUB8`, subtract, four bytes	`SSUB8`	`QSUB8`	`SHSUB8`	`USUB8`	`UQSUB8`	`UHSUB8`

F1.4.8 Divide instructions

In Armv8, signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set.

For descriptions of the instructions see:

- *SDIV* on page F5-4498.
- *UDIV* on page F5-4713.

For the `SDIV` and `UDIV` instructions, division by zero always returns a zero result.

The ID_ISAR0.Divide_instrs field indicates the level of support for these instructions. The field value of `0b0010` indicates they are implemented in both the T32 and A32 instruction sets.

F1.4.9 Miscellaneous data-processing instructions

Table F1-11 lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

Table F1-11 Miscellaneous data-processing instructions

Instruction	See	Notes
BitField Clear	*BFC* on page F5-4120	-
BitField Insert	*BFI* on page F5-4122	-
Count Leading Zeros	*CLZ* on page F5-4144	-
Move Top	*MOVT* on page F5-4352	Moves 16-bit immediate value to top halfword. Bottom halfword unchanged.
Reverse Bits	*RBIT* on page F5-4442	-
Byte-Reverse Word	*REV* on page F5-4444	-
Byte-Reverse Packed Halfword	*REV16* on page F5-4446	-
Byte-Reverse Signed Halfword	*REVSH* on page F5-4448	-
Signed BitField Extract	*SBFX* on page F5-4496	-
Select Bytes using GE flags	*SEL* on page F5-4500	-

F1.5 PSTATE and banked register access instructions

These instructions transfer PE state information to or from a general-purpose register.

F1.5.1 PSTATE access instructions

PSTATE holds process state information, see *Process state, PSTATE* on page E1-3787. In AArch32 state:

- At EL1 or higher, PSTATE is accessible using the *Current Program Status Register* (CPSR).
- At EL0, a subset of the CPSR is accessible as the *Application Program Status Register* (APSR).
- On taking an exception, the contents of the CPSR are copied to the *Saved Program Status Register* (SPSR) of the mode from which the exception is taken.

The `MRS` and `MSR` instructions move the contents of the CPSR, APSR, or the SPSR of the current mode to or from a general-purpose register, see:

- *MRS* on page F5-4358.
- *MSR (immediate)* on page F5-4368.
- *MSR (register)* on page F5-4370.

When executed at EL0, `MRS` and `MSR` instructions can only access the APSR.

The PSTATE Condition flags, PSTATE.{N, Z, C, V} are set by the execution of data-processing instructions, and can control the execution of conditional instructions. However, software can set the Condition flags explicitly using the `MSR` instruction, and can read the current state of the Condition flags explicitly using the `MRS` instruction.

In addition, at EL1 or higher, software can use the `CPS` instruction to change the PSTATE.M field and the PSTATE.{A, I, F} interrupt mask bits, see *CPS, CPSID, CPSIE* on page F5-4160.

F1.5.2 Banked register access instructions

At EL1 or higher, the `MRS` (banked register) and `MSR` (banked register) instructions move the contents of a banked general-purpose register, the SPSR, or the ELR_hyp, to or from a general-purpose register. See:

- *MRS (Banked register)* on page F5-4360.
- *MSR (Banked register)* on page F5-4364.

F1.6 Load/store instructions

Table F1-12 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:

- *Load/store multiple instructions* on page F1-3882.
- *Synchronization and semaphores* on page E2-3853, for more information about the Load-Exclusive and Store-Exclusive instructions.
- *Load-Acquire, Store-Release* on page E2-3828, for more information about the Load-Acquire/Store-Release and Load-Acquire Exclusive/Store-Release Exclusive instructions.
- *Advanced SIMD and floating-point load/store instructions* on page F1-3888.

Load/store instructions have several options for addressing memory. For more information, see *Addressing modes* on page F1-3880.

Table F1-12 Load/store instructions

Data type	Load	Store	Unprivileged		Exclusive		Load-Acquire	Store-Release	Exclusive	
			Load	Store	Load	Store			Load-Acquire	Store-Release
32-bit word	LDR	STR	LDRT	STRT	LDREX	STREX	LDA	STL	LDAEX	STLEX
16-bit halfword	-	STRH	-	STRHT	-	STREXH	LDAH	STLH	LDAEXH	STLEXH
16-bit unsigned halfword	LDRH	-	LDRHT	-	LDREXH	-	-	-	-	-
16-bit signed halfword	LDRSH	-	LDRSHT	-	-	-	-	-	-	-
8-bit byte	-	STRB	-	STRBT	-	STREXB	LDAB	STLB	LDAEXB	STLEXB
8-bit unsigned byte	LDRB	-	LDRBT	-	LDREXB	-	-	-	-	-
8-bit signed byte	LDRSB	-	LDRSBT	-	-	-	-	-	-	-
Two 32-bit words	LDRD	STRD	-	-	-	-	-	-	-	-
64-bit doubleword	-	-	-	-	LDREXD	STREXD	-	-	LDAEXD	STLEXD

F1.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

F1.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F1.6.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an `LDRT` instruction executes in exactly the same way as the equivalent `LDR` instruction. When executed at PL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at EL0. For example, an `LDRT` instruction executes in exactly the way that the equivalent `LDR` instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

Note

As described in *Security state, Exception levels, and AArch32 execution privilege* on page G1-5480, execution at PL1 describes all of the following:

- Execution at Non-secure EL1 using AArch32.
- Execution at Secure EL1 using AArch32 when EL3 is not implemented.
- Execution at Secure EL1 using AArch32 when EL3 is implemented and is using AArch64.
- Execution at Secure EL3 when EL3 is implemented and is using AArch32.

The Load unprivileged and Store unprivileged instructions are CONSTRAINED UNPREDICTABLE if executed at EL2, see *Execution of Load/Store unprivileged instructions in Hyp mode* on page K1-7626.

For more information about execution privilege, see *About access permissions* on page G5-5766.

F1.6.4 Load-Exclusive and Store-Exclusive

Load-Exclusive and Store-Exclusive instructions provide shared memory synchronization. For more information, see *Synchronization and semaphores* on page E2-3853.

F1.6.5 Load-Acquire and Store-Release

Load-Acquire and Store-Release instructions provide memory barriers. Load-Acquire Exclusive and Store-Release Exclusive instructions provide memory barriers with shared memory synchronization. For more information, see *Load-Acquire, Store-Release* on page E2-3828.

F1.6.6 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This provides PC-relative addressing for position-independent code. Instructions marked (literal) in their title in Chapter F2 *About the T32 and A32 Instruction Descriptions* are PC-relative loads.

The offset takes one of three formats:

Immediate The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets and input/output registers.

Register The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data.

Scaled register The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

Offset The offset is added to or subtracted from the base register to form the memory address.

Pre-indexed The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.

Post-indexed The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.

Note

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See Chapter F2 *About the T32 and A32 Instruction Descriptions* for full details for each instruction.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F1.7 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC.

Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table F1-13 summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

Table F1-13 Load/store multiple instructions

Instruction	See
Load Multiple, Increment After or Full Descending	*LDM, LDMIA, LDMFD* on page F5-4224
Load Multiple, Decrement After or Full Ascending [a]	*LDMDA, LDMFA* on page F5-4232
Load Multiple, Decrement Before or Empty Ascending	*LDMDB, LDMEA* on page F5-4234
Load Multiple, Increment Before or Empty Descending [a]	*LDMIB, LDMED* on page F5-4237
Pop multiple registers off the stack [b]	*POP* on page F5-4411
Push multiple registers onto the stack [c]	*PUSH* on page F5-4418
Store Multiple, Increment After or Empty Ascending	*STM, STMIA, STMEA* on page F5-4591
Store Multiple, Decrement After or Empty Descending [a]	*STMDA, STMED* on page F5-4597
Store Multiple, Decrement Before or Full Descending	*STMDB, STMFD* on page F5-4599
Store Multiple, Increment Before or Full Ascending [a]	*STMIB, STMFA* on page F5-4602

a. Not available in the T32 instruction set.
b. This instruction is equivalent to an `LDM` instruction with the SP as base register, and base register updating.
c. This instruction is equivalent to an `STMDB` instruction with the SP as base register, and base register updating.

When executing at EL1, variants of the `LDM` and `STM` instructions load and store User mode registers. Another system level variant of the `LDM` instruction performs an exception return.

F1.7.1 Loads to the PC

The `LDM`, `LDMDA`, `LDMDB`, `LDMIB`, and `POP` instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F1.8 Miscellaneous instructions

Table F1-14 summarizes the miscellaneous instructions in the T32 and A32 instruction sets.

Table F1-14 Miscellaneous instructions

Instruction	See
Clear-Exclusive	*CLREX* on page F5-4143
Data Memory Barrier	*DMB* on page F5-4180
Data Synchronization Barrier	*DSB* on page F5-4183
Error Synchronization Barrier	*ESB* on page F5-4197
Instruction Synchronization Barrier	*ISB* on page F5-4203
If-Then	*IT* on page F5-4204[a]
No Operation	*NOP* on page F5-4382
Preload Data	*PLD, PLDW (immediate)* on page F5-4400 *PLD (literal)* on page F5-4402 *PLD, PLDW (register)* on page F5-4404
Preload Instruction	*PLI (immediate, literal)* on page F5-4406 *PLI (register)* on page F5-4409
Speculation Barrier	*SB* on page F5-4485
Set Endianness	*SETEND* on page F5-4502[b]
Set Privileged Access Never	*SETPAN* on page F5-4503
Send Event	*SEV* on page F5-4504
Send Event Local	*SEVL* on page F5-4506
Wait For Event	*WFE* on page F5-4771
Wait For Interrupt	*WFI* on page F5-4773
Yield	*YIELD* on page F5-4775[c]

a. For performance reasons, Arm deprecates many uses of the `IT` instruction, see *Partial deprecation of IT* on page F1-3884.

b. Arm deprecates any use of the `SETEND` instruction.

c. See also *The Yield instruction*.

Note

Previous versions of the architecture defined the `DBG` instruction, that could provide a hint to the debug system, in this group. In Armv8, this instruction executes as a `NOP`. Arm deprecates any use of the `DBG` instruction.

F1.8.1 The Yield instruction

In a *Symmetric Multithreading* (SMT) design, a thread can use the `YIELD` instruction to give a hint to the PE that it is running on. The `YIELD` hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AArch32 state defines a YIELD instruction as a specific NOP (No Operation) hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

F1.8.2 Partial deprecation of IT

Armv8-A deprecates some uses of the T32 IT instruction, for performance reasons. All uses of IT that apply to instructions other than a single subsequent 16-bit instruction from a restricted set are deprecated, as are explicit references to the PC within that single 16-bit instruction. This permits the non-deprecated forms of IT and subsequent instructions to be treated as a single 32-bit conditional instruction. Table F1-15 shows the restricted set of 16-bit instructions that are not deprecated when used in conjunction with IT.

Table F1-15 Non-deprecated IT 16-bit conditional instructions

Non-deprecated 16-bit instructions	Class	Notes
MOV, MVN	Move	Deprecated when Rm or Rd is the PC.
LDR, LDRB, LDRH, LDRSB, LDRSH	Load	Deprecated for PC-relative load literal forms
STR, STRB, STRH	Store	-
ADD, ADC, RSB, SBC, SUB	Add/Subtract	Deprecated for ADD SP,SP,#imm, SUB SP,SP,#imm, and when Rm, Rdn, or Rdm is the PC
CMP, CMN	Compare	Deprecated when Rm or Rn is the PC
MUL	Multiply	-
ASR, LSL, LSR, ROR	Shift	-
AND, BIC, EOR, ORR, TST	Logical	-
BX, BLX	Branch to register	Deprecated when Rm is the PC

The full Armv7 IT instruction functionality remains available in order to execute legacy T32 code. It is IMPLEMENTATION DEFINED whether an Armv8 implementation provides an ITD control, that software can use to disable the deprecated uses of the IT instruction. In an implementation that included the ITD control, setting an ITD field to 1 disables the deprecated uses of the IT instruction, making those uses of the IT instruction UNDEFINED. The ITD control fields are:

HSCTLR.ITD When EL2 is using AArch32, makes execution of the deprecated uses of the IT UNDEFINED at EL2.

SCTLR.ITD When EL1 is using AArch32, makes execution of the deprecated uses of the IT UNDEFINED at EL0 and EL1.

SCTLR_EL1.ITD

When EL1 is using AArch64, makes execution of the deprecated uses of the IT UNDEFINED at EL0 when EL0 is using AArch32.

F1.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The SVC instruction generates a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception* on page G1-5540.
- The Breakpoint instruction BKPT provides software breakpoints. For more information, see *Breakpoint Instruction exceptions* on page G2-5625.
- In an implementation that includes EL3 the SMC instruction generates a Secure Monitor Call exception. For more information, see *Secure Monitor Call (SMC) exception* on page G1-5541.
- In an implementation that includes EL2 the HVC instruction generates a Hypervisor Call exception. For more information, see *Hypervisor Call (HVC) exception* on page G1-5542.

Debug state on page F1-3886 summarizes the Debug state instructions.

For an exception taken to an EL1 mode:

- The system level variants of the SUBS and LDM instructions can perform a return from an exception.

  Note

  The variants of SUBS include MOVS. See the references to *Subtract (exception return)*, *Move (exception return)*, and *Load Multiple (exception return)* in Table F1-16 for more information.

- The SRS instruction can be used near the start of the handler, to store return information. The RFE instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the ERET instruction performs a return from an exception taken to Hyp mode.

For more information, see *Exception return to an Exception level using AArch32* on page G1-5523.

Table F1-16 summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for BKPT and SVC, these are system level instructions.

Table F1-16 Exception-generating and exception-handling instructions

Instruction	See
Supervisor Call	*SVC* on page F5-4673
Breakpoint	*BKPT* on page F5-4133
Secure Monitor Call	*SMC* on page F5-4520
Return From Exception	*RFE, RFEDA, RFEDB, RFEIA, RFEIB* on page F5-4450
Subtract (exception return)[a]	*SUB, SUBS (immediate)* on page F5-4657[a]
Move (exception return)[a]	*MOV, MOVS (register)* on page F5-4343[a]
Hypervisor Call	*HVC* on page F5-4201
Exception Return	*ERET* on page F5-4195
Load Multiple (exception return)	*LDM (exception return)* on page F5-4228
Store Return State	*SRS, SRSDA, SRSDB, SRSIA, SRSIB* on page F5-4555

a. The A32 instruction set includes other instruction forms that can be used for an exception return, that have previously been described as variants of SUBS PC, LR. Arm deprecates any use of these instruction forms.

F1.10 System register access instructions

The System register encoding space is indexed using the parameters {coproc, opc1, CRn, CRm, opc2}, see *The AArch32 System register interface* on page G1-5567. This encoding space provides System registers and System instructions. In Armv8, the only permitted values of coproc are 0b1110 and 0b1111, and the following instructions give access to this encoding space:

- Instructions that transfer data between general-purpose registers and System registers. See:
  - *MCR* on page F5-4331.
  - *MCRR* on page F5-4333.
  - *MRC* on page F5-4354.
  - *MRRC* on page F5-4356.
- Instructions that load or store from memory to a System register. See:
  - *LDC (immediate)* on page F5-4220.
  - *LDC (literal)* on page F5-4222.
  - *STC* on page F5-4571.

Note

The System register encoding space with coproc==0b101x is redefined to provide some of the Advanced SIMD and floating-point functionality. That is, to:

- Initiate a floating-point data-processing operation, see *Floating-point data-processing instructions* on page F1-3901.
- Transfer data between general-purpose registers and the Advanced SIMD and floating-point registers, see *Advanced SIMD and floating-point register transfer instructions* on page F1-3890.
- Load or store data to the Advanced SIMD and floating-point registers, see *Advanced SIMD and floating-point load/store instructions* on page F1-3888.

System register access instructions are part of the instruction stream executed by the PE, and therefore any System register access instruction that cannot be executed by the implementation causes an Undefined Instruction exception. In Armv8-A and Armv8-R, the instruction encodings in the System register access instruction encoding space are unallocated, and generate Undefined Instruction exceptions, except for:

- The instructions summarized in this section that access the coproc==0b111x encoding space.
- The instructions in the coproc==0b101x encoding space that are redefined to provide Advanced SIMD and floating-point functionality, as summarized in the Note in this section.

F1.11 Advanced SIMD and floating-point load/store instructions

Table F1-18 summarizes the SIMD and floating-point register file load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see *Element and structure load/store instructions*.

Table F1-18 SIMD and floating-point register file load/store instructions

Instruction	See	Operation
Vector Load Multiple	*VLDM, VLDMDB, VLDMIA* on page F6-5071	Load 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Load 1-16 consecutive 32-bit registers, floating-point only.
Vector Load Register	*VLDR (immediate)* on page F6-5076 *VLDR (literal)* on page F6-5079	Load one 64-bit register, Advanced SIMD and floating-point. Load one 32-bit register, floating-point only.
Vector Store Multiple	*VSTM, VSTMDB, VSTMIA* on page F6-5425	Store 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Store 1-16 consecutive 32-bit registers, floating-point only.
Vector Store Register	*VSTR* on page F6-5430	Store one 64-bit register, Advanced SIMD and floating-point. Store one 32-bit register, floating-point only.

F1.11.1 Element and structure load/store instructions

Table F1-19 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see Figure F1-1 on page F1-3889 for an example of de-interleaving. Interleaving is the inverse process.

Table F1-19 Element and structure load/store instructions

Instruction	See
Load single element	
Multiple elements	*VLD1 (multiple single elements)* on page F6-5025
To one lane	*VLD1 (single element to one lane)* on page F6-5017
To all lanes	*VLD1 (single element to all lanes)* on page F6-5022
Load 2-element structure	
Multiple structures	*VLD2 (multiple 2-element structures)* on page F6-5042
To one lane	*VLD2 (single 2-element structure to one lane)* on page F6-5033
To all lanes	*VLD2 (single 2-element structure to all lanes)* on page F6-5039
Load 3-element structure	
Multiple structures	*VLD3 (multiple 3-element structures)* on page F6-5056
To one lane	*VLD3 (single 3-element structure to one lane)* on page F6-5047
To all lanes	*VLD3 (single 3-element structure to all lanes)* on page F6-5053

Table F1-19 Element and structure load/store instructions (continued)

Instruction	See
Load 4-element structure	
Multiple structures	*VLD4 (multiple 4-element structures)* on page F6-5068
To one lane	*VLD4 (single 4-element structure to one lane)* on page F6-5059
To all lanes	*VLD4 (single 4-element structure to all lanes)* on page F6-5065
Store single element	
Multiple elements	*VST1 (multiple single elements)* on page F6-5388
From one lane	*VST1 (single element from one lane)* on page F6-5383
Store 2-element structure	
Multiple structures	*VST2 (multiple 2-element structures)* on page F6-5402
From one lane	*VST2 (single 2-element structure from one lane)* on page F6-5396
Store 3-element structure	
Multiple structures	*VST3 (multiple 3-element structures)* on page F6-5413
From one lane	*VST3 (single 3-element structure from one lane)* on page F6-5407
Store 4-element structure	
Multiple structures	*VST4 (multiple 4-element structures)* on page F6-5422
From one lane	*VST4 (single 4-element structure from one lane)* on page F6-5416

Figure F1-1 shows the de-interleaving of a `VLD3.16` (multiple 3-element structures) instruction:

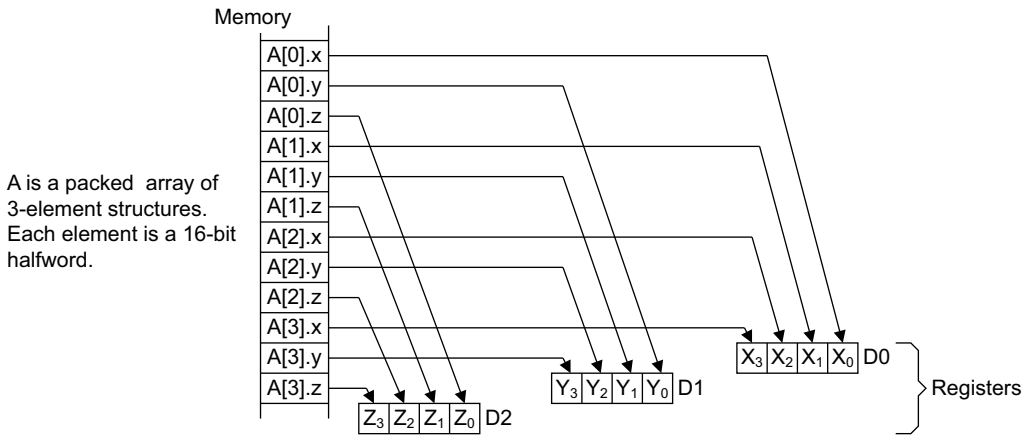

Figure F1-1 De-interleaving an array of 3-element structures

Figure F1-1 shows the `VLD3.16` instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, `VLD4` and `VST4` instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.

F1.12 Advanced SIMD and floating-point register transfer instructions

Table F1-20 summarizes the SIMD and floating-point register file transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data between the general-purpose registers and the registers in the SIMD and floating-point register file.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same register file. For details see *The SIMD and floating-point register file* on page E1-3794.

Table F1-20 SIMD and floating-point register file transfer instructions

Instruction	See
Copy element from general-purpose register to every element of an Advanced SIMD vector	*VDUP (general-purpose register)* on page F6-4971
Copy byte, halfword, or word from general-purpose register to a register in the SIMD and floating-point register file	*VMOV (general-purpose register to scalar)* on page F6-5141
Copy byte, halfword, or word from a register in the SIMD and floating-point register file to a general-purpose register	*VMOV (scalar to general-purpose register)* on page F6-5145
Copy from half-precision floating-point register to general-purpose register, or from general-purpose register to half-precision floating-point register Only supported if ARMv8.2-FP16 is implemented	*VMOV (between general-purpose register and half-precision)* on page F6-5128
Copy from single-precision floating-point register to general-purpose register, or from general-purpose register to single-precision floating-point register	*VMOV (between general-purpose register and single-precision)* on page F6-5143
Copy two words from general-purpose registers to consecutive single-precision floating-point registers, or from consecutive single-precision floating-point registers to general-purpose registers	*VMOV (between two general-purpose registers and two single-precision registers)* on page F6-5147
Copy two words from general-purpose registers to a doubleword register in the SIMD and floating-point register file, or from a doubleword register in the SIMD and floating-point register file to general-purpose registers	*VMOV (between two general-purpose registers and a doubleword floating-point register)* on page F6-5126
Copy from an Advanced SIMD and floating-point System Register to a general-purpose register	*VMRS* on page F6-5156

F1.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. Figure F1-2 shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

Note

Figure F1-2 and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with one, two, eight, or sixteen operations performed in parallel instead of four.

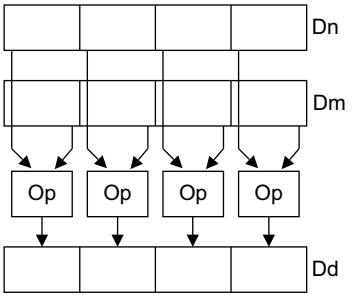

Figure F1-2 Advanced SIMD instruction operating on 64-bit registers

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

Figure F1-3 shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

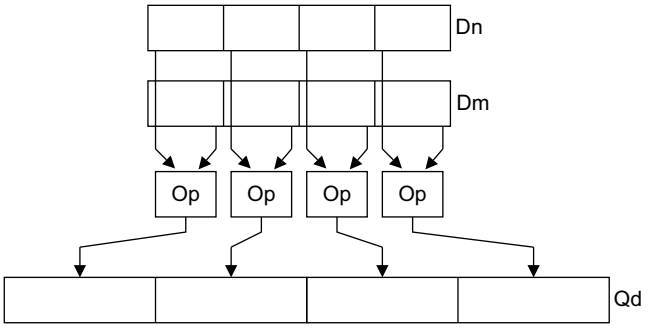

Figure F1-3 Advanced SIMD instruction producing wider result

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. Figure F1-4 on page F1-3892 shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.

Non-Confidential

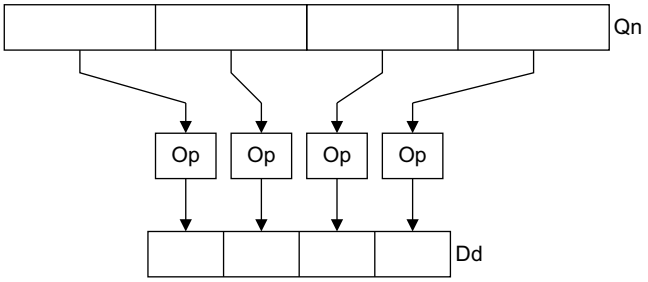

Figure F1-4 Advanced SIMD instruction producing narrower result

Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the Arm standard floating-point arithmetic defined in *Advanced SIMD and floating-point support* on page A1-51.

The following sections summarize the Advanced SIMD data-processing instructions:

- *Advanced SIMD parallel addition and subtraction*.
- *Bitwise Advanced SIMD data-processing instructions* on page F1-3893.
- *Advanced SIMD comparison instructions* on page F1-3894.
- *Advanced SIMD shift instructions* on page F1-3895.
- *Advanced SIMD multiply instructions* on page F1-3896.
- *Advanced SIMD dot product instructions* on page F1-3897.
- *Miscellaneous Advanced SIMD data-processing instructions* on page F1-3898.
- *The Cryptographic Extension in AArch32 state* on page F1-3899.

F1.13.1 Advanced SIMD parallel addition and subtraction

Table F1-21 shows the Advanced SIMD parallel add and subtract instructions.

Vector Saturating Rounding Doubling Multiply Subtract Returning High Half	*VQRDMLSH* on page F6-5251
Vector Saturating Rounding Doubling Multiply Returning High Half	*VQRDMULH* on page F6-5255

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over {0, 1}. `VMUL` and `VMULL` are the only instructions that operate on polynomials. `VMULL` produces a 16-bit polynomial over {0, 1}.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Single-precision (32-bit) or half-precision (16-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- Half-precision (16-bit) floating-point numbers.
- Single-precision (32-bit) floating-point numbers.
- Double-precision (64-bit) floating-point numbers.

F1.13.6 Advanced SIMD dot product instructions

ARMv8.2-DotProd provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

Vector form The dot product is calculated for each element of the first vector with the corresponding element of the second element.

Indexed form The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

Note

That is, a single element from the second vector is used, and a the dot product is calculated between each element of the first vector and this single element from the second vector.

Table F1-26 Advanced SIMD dot product instructions

Mnemonic	Instruction	See
VSDOT	Signed dot product (vector form)	*VSDOT (vector)* on page F6-5348
VUDOT	Unsigned dot product (vector form)	*VUDOT (vector)* on page F6-5457
VSDOT	Signed dot product (indexed form)	*VSDOT (by element)* on page F6-5346
VUDOT	Unsigned dot product (indexed form)	*VUDOT (by element)* on page F6-5455

F1.13.7 Advanced SIMD complex number arithmetic instructions

ARMv8.3-CompNum provides AArch32 Advanced SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide single-precision versions. If ARMv8.2-FP16 is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.

Chapter F2
About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Format of instruction descriptions* on page F2-3904.
- *Standard assembler syntax fields* on page F2-3908.
- *Conditional execution* on page F2-3909.
- *Shifts applied to a register* on page F2-3911.
- *Memory accesses* on page F2-3913.
- *Encoding of lists of general-purpose registers and the PC* on page F2-3914.
- *General information about the T32 and A32 instruction descriptions* on page F2-3915.
- *Additional pseudocode support for instruction descriptions* on page F2-3928.
- *Additional information about Advanced SIMD and floating-point instructions* on page F2-3929.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F2.1 Format of instruction descriptions

The instruction descriptions in Chapter F5 *T32 and A32 Base Instruction Set Instruction Descriptions* and Chapter F6 *T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions* normally use the following format:

- Instruction section title.
- Introduction to the instruction.
- A description of each encoding of the instruction.
- Assembler syntax.
- Pseudocode describing how the instruction operates.
- Notes, if applicable.

Each of these items is described in more detail in the following subsections.

F2.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instruction or instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

F2.1.2 Introduction to the instruction

The introduction to the instruction briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

F2.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labelled as:

- A1, A2, A3 … for the first, second, third and any additional A32 encodings.
- T1, T2, T3 … for the first, second, third and any additional T32 encodings.

Each instruction encoding description consists of:

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. In some cases, multiple syntax variants are given. These are written in a `typewriter` font using the conventions described in *Assembler syntax prototype line conventions* on page F2-3906. The correct one to use can be indicated by:
  - A subheading that identifies the encodings that correspond to the syntax. See, for example, the subheading *Flag setting, rotate right with extend variant* in the description of the A1 encoding of the `ADC`, `ADCS` (register) instructions in *A1* on page F5-4072.
  - An annotation to the syntax, such as *Inside IT block* or *Outside IT block*. See, for example, the syntax descriptions of the T1 encoding of the `ADC`, `ADCS` (register) instructions in *T1* on page F5-4073.

  In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

  There is usually more than one syntax variant that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax `AND R0, R0, R8` ensures selection of a 32-bit encoding but `AND R0, R0, R1` selects a 16-bit encoding.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction then:

— If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture *prefers* the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding.

  Software can use the `.W` and `.N` qualifiers to specify the required encoding width, see *Standard assembler syntax fields* on page F2-3908.

— If multiple encodings of the same length can encode the instruction, the *Assembler syntax* subsection says which encoding is preferred, and how software can, instead, select the other encodings.

  Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

Note

In some cases, an instruction is available in one instruction set but not in another. The *Assembler syntax* subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == `0b1111` described in *Branch, branch with link, and block data transfer* on page F4-4032, *System register access, Advanced SIMD, floating-point, and Supervisor call* on page F4-4034, and *Unconditional instructions* on page F4-4048 cannot have a Condition code, but the equivalent T32 instructions often can, and this usually appears in the *Assembler syntax* subsection as a statement that the A32 instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the operand combination, in order to produce more readable disassembled code.

- An encoding diagram, where:

  — For a 32-bit A32 encoding diagram, the bits are numbered from 31 to 0.

  — For a 16-bit T32 encoding diagram, the bits are numbered from 15 to 0.

    This halfword can be described as `hw1` of the instruction.

  — For a 32-bit T32 encoding diagram, the bits are numbered from 15 to 0 for each halfword, as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word.

    In this case, the left-hand halfword in the diagram is identified as `hw1`, and the right-hand halfword is identified as `hw2`.

  Where instructions are stored using the standard little-endian instruction endianness:

  — The encoding diagram for an A32 instruction at address A shows, from left to right, the bytes at addresses A+3, A+2, A+1, A.

  — The encoding diagram for a 32-bit T32 instruction shows bytes in the order A+1, A for `hw1`, followed by bytes A+3, A+2 for `hw2`.

- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix K13 *Arm Pseudocode Definition*.

F2.1.4 Assembler symbols

The *Assembly symbols* describes the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

- Descriptions of all of the variable or optional fields of the syntax.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Some syntax fields are standardized across all or most instructions. *Standard assembler syntax fields* on page F2-3908 describes these fields.

By default, syntax fields that specify registers, such as <Rd>, <Rn>, or <Rt>, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as d, n, or t) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

— Normally, software can do this by setting the corresponding field in the instruction, typically named Rd, Rn, Rt, to the binary encoding of that number.

— In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is only available when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like Rdn. This indicates that the encoding is only available if <Rd> and <Rn> specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

- Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. Arm recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

Assembler syntax prototype line conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

< > Any item bracketed by < and > is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence only requires the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item <Rn> and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as `add = TRUE`. The assembler must only use encodings that produce that output.

{ } Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

- Must treat the # as optional where an instruction syntax description shows it as optional.
- Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

Note

Arm recommends that UAL assemblers treat all uses of # shown in this manual as optional.

spaces Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

+/- This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters must be encoded as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

F2.1.5 Pseudocode describing how the instruction operates

The *Operation for all classes* subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix K13 *Arm Pseudocode Definition*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F2.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

`<c>` Is an optional field. It specifies the condition under which the instruction is executed. See *Conditional execution* on page F2-3909 for the range of available conditions and their encoding. If `<c>` is omitted, it defaults to *always* (`AL`).

`<q>` Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

- `.N` Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.
- `.W` Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither `.W` nor `.N` is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description. The assembler syntax includes a mandatory `.W` qualifier, along with a note describing the cases in which it applies, where this qualifier is required to select a particular encoding for an instruction. Additional assembler syntax will describe the syntax when the conditions are not met.

Note

When assembling to the A32 instruction set, the `.N` qualifier produces an assembler error and the `.W` qualifier has no effect.

Non-Confidential

F2.3 Conditional execution

Most T32 and A32 instructions can be executed conditionally, based on the values of the APSR Condition flags. Table F2-1 lists the available conditions.

Table F2-1 Condition codes

cond	Mnemonic extension	Meaning (integer)	Meaning (floating-point) [a]	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal, or unordered	Z == 0
0010	CS [b]	Carry set	Greater than, equal, or unordered	C == 1
0011	CC [c]	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Not unordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C == 1 and Z == 0
1001	LS	Unsigned lower or same	Less than or equal	C == 0 or Z == 1
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N != V
1100	GT	Signed greater than	Greater than	Z == 0 and N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	Z == 1 or N != V
1110	None (AL) [d]	Always (unconditional)	Always (unconditional)	Any

a. Unordered means at least one NaN operand.
b. HS (unsigned higher or same) is a synonym for CS.
c. LO (unsigned lower) is a synonym for CC.
d. AL is an optional mnemonic extension for always, except in IT instructions. For details see *IT* on page F5-4204.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information see *Conditional instructions* on page F1-3867 and *IT* on page F5-4204. Some conditional branch instructions do not require a preceding IT instruction, because they include a Condition code in their encoding.

For performance reasons, Armv8 deprecates the use of IT other than with a single 16-bit T32 instruction from a specified subset of the 16-bit T32 instructions, see *Partial deprecation of IT* on page F1-3884. In addition, implementations can provide a set of ITD control fields, SCTLR.ITD, SCTLR_EL1.ITD, and HSCTLR.ITD, to disable these deprecated uses, making them UNDEFINED. For more information see:

- *Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality* on page G1-5579.
- *Disabling or enabling EL2 use of AArch32 deprecated functionality* on page G1-5588.

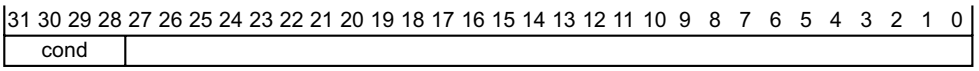
In A32 instructions, bits[31:28] of the instruction contain either:

- The Condition code, see *The Condition code field in A32 instruction encodings* on page F2-3910.
- 0b1111 for some A32 instructions that can only be executed unconditionally.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F2.3.1 The Condition code field in A32 instruction encodings

Every conditional A32 instruction contains a 4-bit Condition code field, the `cond` field, in bits 31 to 28:



This field contains one of the values `0b0000-0b1110`, as shown in Table F2-1 on page F2-3909. Most instruction mnemonics can be extended with the letters defined in the *Mnemonic extension* on page F2-3909 column of that table.

If the *always* (`AL`) condition is specified, the instruction is executed irrespective of the value of the Condition flags. The absence of a Condition code on an instruction mnemonic implies the `AL` Condition code.

F2.3.2 Pseudocode description of conditional execution

The `AArch32.CurrentCond()` function returns a 4-bit condition specifier as follows:

- For A32 instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see *B* on page F5-4117), it returns the 4-bit `cond` field of the encoding.
- For all other T32 instructions:
  - If `PSTATE.IT<3:0> != '0000'` it returns `PSTATE.IT<7:4>`.
  - If `PSTATE.IT<7:0> == '00000000'` it returns `'1110'`.
  - Otherwise, execution of the instruction is CONSTRAINED UNPREDICTABLE.

  For more information, see *Process state, PSTATE* on page E1-3787.

The `ConditionPassed()` function uses this condition specifier and the Condition flags to determine whether the instruction must be executed, by calling the `ConditionHolds()` function.

Chapter J1 *Armv8 Pseudocode* includes the definitions of these functions.

Undefined Instruction exception on page G1-5536 describes the handling of conditional instructions that are UNDEFINED, UNPREDICTABLE, or CONSTRAINED UNPREDICTABLE. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see *Limitations of the instruction pseudocode* on page K13-7784.

Non-Confidential

F2.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details see *Constant shifts*.

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

F2.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions.

`<shift>` is an optional shift to be applied to `<Rm>`. It can be any one of:

(omitted) No shift.

`LSL #<n>` Logical shift left `<n>` bits. 1 <= `<n>` <= 31.

`LSR #<n>` Logical shift right `<n>` bits. 1 <= `<n>` <= 32.

`ASR #<n>` Arithmetic shift right `<n>` bits. 1 <= `<n>` <= 32.

`ROR #<n>` Rotate right `<n>` bits. 1 <= `<n>` <= 31.

`RRX` Rotate right one bit, with extend. Bit[0] is written to `shifter_carry_out`, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

Note

Assemblers can permit the use of some or all of `ASR #0`, `LSL #0`, `LSR #0`, and `ROR #0` to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of `#0` in the immediate forms of `ASR`, `LSL`, `LSR`, and `ROR` instructions to specify that no shift is to be performed, that is, that a `MOV` (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the `MOV` (register) syntax when the instruction specifies no shift.

Encoding

The assembler encodes `<shift>` into two type bits and five immediate bits, as follows:

(omitted) type = `0b00`, immediate = 0.

`LSL #<n>` type = `0b00`, immediate = `<n>`.

`LSR #<n>` type = `0b01`.
If `<n>` < 32, immediate = `<n>`.
If `<n>` == 32, immediate = 0.

`ASR #<n>` type = `0b10`.
If `<n>` < 32, immediate = `<n>`.
If `<n>` == 32, immediate = 0.

`ROR #<n>` type = `0b11`, immediate = `<n>`.

`RRX` type = `0b11`, immediate = 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F2.4.2 Register controlled shifts

These are only available in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

ASR — Arithmetic shift right, encoded as type = 0b10.

LSL — Logical shift left, encoded as type = 0b00.

LSR — Logical shift right, encoded as type = 0b01.

ROR — Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

F2.4.3 Pseudocode description of instruction-specified shifts and rotates

The pseudocode enumeration SRType{} defines the shift types. Shift and rotate instruction decode is described by the pseudocode function:

- DecodeImmShift() for a constant shift.
- DecodeRegShift() for a register controlled shift.

Shift and rotate operations are made by the pseudocode function Shift().

Non-Confidential

F2.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

`[<Rn>, <offset>]`

Pre-indexed addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

`[<Rn>, <offset>]!`

Post-indexed addressing

The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register

The assembly language syntax for this mode is:

`[<Rn>], <offset>`

In each case, `<Rn>` is the base register. `<offset>` can be:

- An immediate constant, such as `<imm8>` or `<imm12>`.
- An index register, `<Rm>`.
- A shifted index register, such as `<Rm>, LSL #<shift>`.

For information about unaligned access, endianness, and exclusive access, see:

- *Alignment support* on page E2-3834.
- *Endian support* on page E2-3836.
- *Synchronization and semaphores* on page E2-3853.

Non-Confidential

F2.6 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a `<registers>` field, that provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit `register_list` field. This section gives more information about these and other possible register list encodings.

In a `register_list` field, each bit corresponds to a single register, and if the `<registers>` field of the assembler instruction includes Rt then `register_list<t>` is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.

  The exceptions to this rule are:

  — The T1 encoding of `POP` uses an 8-bit register list, and an additional bit, `P`, that corresponds to the PC. This means it can access any of R0-R7 and the PC.

  — The T1 encoding of `PUSH` uses an 8-bit register list, and an additional bit, `M`, that corresponds to the LR. This means it can access any of R0-R7 and the LR.

- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, `M`, corresponding to the LR, and `P`, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.

- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, `M`, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.

- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.

  The exception to this rule is:

  — The System instructions `LDM` (exception return) and `LDM` (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.

- The T3 and A2 encodings of `POP`, and the T3 and A2 encodings of `PUSH`, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the `Rt` field.

Note

`POP` is a load operation, and `PUSH` is a store operation.

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, `registers`, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

Note

Some Advanced SIMD and floating-point instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a `<list>` field that specifies the registers to be operated on, and the description of the instruction in *Alphabetical list of T32 and A32 base instruction set instructions* on page F5-4068 defines the use and encoding of this field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F2.7 General information about the T32 and A32 instruction descriptions

Chapter F3 *T32 Instruction Set Encoding* describes the T32 instruction encodings, and Chapter F4 *A32 Instruction Set Encoding* describes the A32 instruction encodings. The following subsections give more information about the descriptions of these instructions and their encodings:

- *Execution of instructions in debug state*.
- *Fixed values in AArch32 instruction and System register descriptions*.
- *UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space* on page F2-3916.
- *T32 and A32 Advanced SIMD and floating-point instruction encodings* on page F2-3917.
- *The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions* on page F2-3921.
- *The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions* on page F2-3922.
- *Modified immediate constants in T32 and A32 instructions* on page F2-3922.

F2.7.1 Execution of instructions in debug state

In general, except for the instructions described in *Debug state* on page F1-3886, the T32 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see *Executing instructions in Debug state* on page H2-6715.

Note

- A32 instructions cannot be executed in Debug state.
- For many T32 instructions, execution is unchanged in Debug state. *Executing instructions in Debug state* on page H2-6715 identifies these instructions,

F2.7.2 Fixed values in AArch32 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ Read-As-Zero. See *Read-As-Zero (RAZ)*.

In diagrams, a RAZ bit can be shown as 0.

(0), RES0 Reserved, *Should-Be-Zero (SBZ)* or *RES0*.

In instruction encoding diagrams, and sometimes in other descriptions, `(0)` indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either `(0)(0)(0)` or as `(000)`.

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the Glossary definition of RES0 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The (0) and RES0 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

RAO Read-As-One. See *Read-As-One (RAO)*.

In diagrams, a RAO bit can be shown as 1.

(1), RES1 Reserved, *Should-Be-One (SBO)* or *RES1*.

In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates a SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the Glossary definition of RES1 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES1 fields,

The (1) and RES1 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

Note

In register diagrams, (0) is a synonym for RES0, and (1) is a synonym for RES1, where RES0 and RES1 are defined in the *Glossary*. However, when used in an instruction encoding diagram, (0) and (1) have the narrower definition that behavior is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE if either:

- A bit marked as (0) has the value 1.
- A bit marked as (1) has the value 0.

F2.7.3 UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE.

  Armv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Most cases that earlier versions of the architecture describe as UNPREDICTABLE become either:

  — CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.

  — Fully predictable.

  For more information see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in Chapter F3 *T32 Instruction Set Encoding* or Chapter F4 *A32 Instruction Set Encoding*.

An instruction is UNPREDICTABLE only if:

- It is declared as UNPREDICTABLE in an instruction description or in Chapter F3 or Chapter F4, and Appendix K1 does not redefine the behavior as CONSTRAINED UNPREDICTABLE.
- The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively. In most cases, Armv8 makes these cases CONSTRAINED UNPREDICTABLE, as described in *SBZ or SBO fields T32 and A32 in instructions* on page K1-7610.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Unless otherwise specified, T32 and A32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

Note

Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The System instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

For more information about UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction behavior, see *Undefined Instruction exception* on page G1-5536.

F2.7.4 T32 and A32 Advanced SIMD and floating-point instruction encodings

The T32 and A32 encodings of Advanced SIMD and floating-point instructions that are described in Chapter F3 *T32 Instruction Set Encoding* and in Chapter F4 *A32 Instruction Set Encoding* are common to the T32 and A32 instruction sets. This means:

- The instruction groups, and the set of instructions in each group, are identical for T32 and A32.
- For each instruction:
  - Each T32 encoding is exactly equivalent to an A32 encoding.
  - There is no T32 encoding without an equivalent A32 encoding, and no A32 encoding without an equivalent T32 encoding.

Note

- In the T32 instruction sets, the Advanced SIMD and floating-point instructions have 32-bit encodings.
- In the base instruction sets, some instructions are common to the T32 and A32 instruction sets, whereas other instructions have equivalent but not identical functionality in the two instruction sets.

32-bit T32 encodings are described as two contiguous halfwords, `{hw1:hw2}`, as described in *Instruction encodings* on page F2-3904. In general:

- `hw1` of a T32 encoding maps onto bits[31:16] of an equivalent A32 encoding.
- `hw2` of a T32 encoding maps onto bits[15:0] of an equivalent A32 encoding.

However, the different structures of the T32 instruction encoding space and the A32 instruction encoding space mean that:

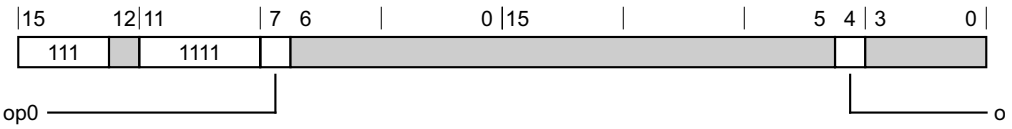
- For a given Advanced SIMD and floating-point instruction group:
  - The positions of the fields that identify the instruction, or instruction encoding, within the instruction group might differ between the T32 encodings and the A32 encodings.
  - However, the field values that identify the instruction of instruction encoding are identical for the T32 encoding and the A32 encoding.

The remainder of this section describes the equivalence of the T32 and A32 encodings for each of the Advanced SIMD and floating-point instruction groups.

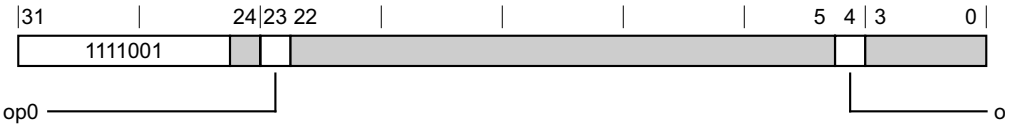
Advanced SIMD data-processing

The T32 encoding of the Advanced SIMD data-processing group is:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



The A32 encoding of the Advanced SIMD data-processing group is:



The encodings in this group are identified by:

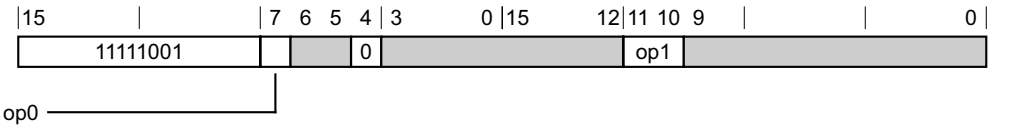
- `hw1`[15:13] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and:
  - Has the value `0b111` in the T32 encoding.
  - Has the value `0b001` in the A32 encoding.
- `hw1`[11:8] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value `0b111`.

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

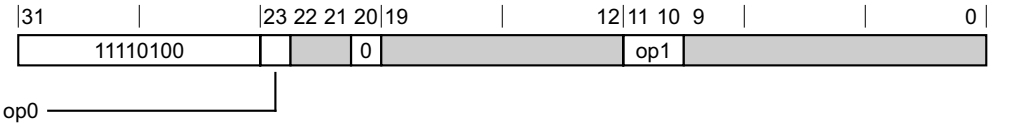
T32 encoding	A32 encoding	Field size
`op0:op1`	`op0`	2 bits
`op2`	`op1`	15 bits
`op3`	`op2`	1 bit
`op4`	`op3`	1 bit

Advanced SIMD element or structure load/store

The T32 encoding of the Advanced SIMD element or structure load/store group is:



The A32 encoding of the Advanced SIMD element or structure load/store group is:



The encodings in this group are identified by:

- `hw1`[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value `0b1111`.

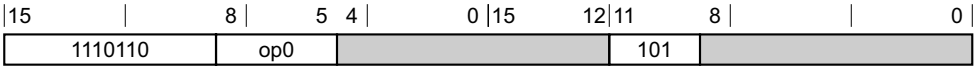
Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and:
  - Has the value 0b1001 in the T32 encoding.
  - Has the value 0b0100 in the A32 encoding.
- hw1[4] of the T32 encoding is equivalent to bit[20] of the A32 encoding, and has the value 0b0.

op0, op1, and op2 are the fields that identify the instructions, or instruction encodings, within this group, and they are in equivalent positions in the T32 and A32 encodings.

Floating-point and Advanced SIMD load/store and 64-bit register moves

The T32 encoding of the Floating-point and Advanced SIMD load/store and 64-bit register moves group is:



The A32 encoding of the Floating-point and Advanced SIMD load/store and 64-bit register moves group is:

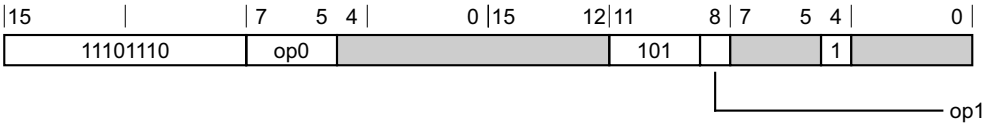
The encodings in the group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  - Has the value 0b1110 in the T32 encoding.
  - Can have any value other than 0b1111 in the A32 encoding.
    This range of values is required because A32 instructions in this group can be executed conditionally, see *Conditional execution* on page F2-3909.
- hw1[11:9] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and has the value 0b110.
- hw2[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value 0b101.

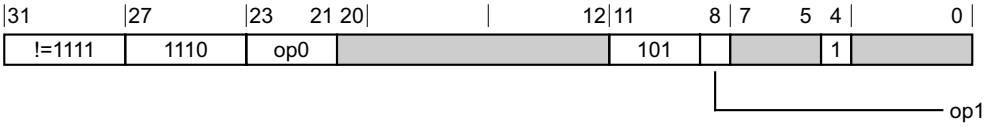
op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

Floating-point and Advanced SIMD 32-bit register moves

The T32 encoding of the Floating-point and Advanced SIMD 32-bit register moves group is:



The A32 encoding of the Advanced SIMD 32-bit register moves group is:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The encodings in this group are identified by:

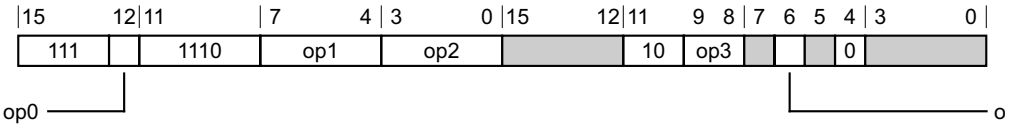
- `hw1`[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  - Has the value `0b1110` in the T32 encoding.
  - Can have any value other than `0b1111` in the A32 encoding.

    This range of values is required because A32 instructions in this group can be executed conditionally, see *Conditional execution* on page F2-3909.
- `hw1`[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value `0b1110`.
- `hw2`[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value `0b101`.
- `hw2`[4] of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value `0b1`.

`op0` is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

Floating-point data-processing

The T32 encoding of the Floating-point data-processing group is:



The A32 encoding of the Floating-point data-processing group is:

The encodings in this group are identified by:

- `hw1`[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
  - In the T32 encoding, `hw1`[15:13] has the value `0b111`, and `hw1`[12] is the `op0` parameter used in identifying instruction encodings within this group.
  - In the A32 encoding, is the `cond` field and also implies the value of bit[28] of some A32 instruction encodings within this group, as the following table shows:

cond	Significance of bit[28] in A32 encodings
!= `0b1111`	Part of the `cond` field.
`0b1111`	Has fixed value of 1.

    The range of `cond` values other than `0b1111` is required because A32 instructions in this group can be executed conditionally, see *Conditional execution* on page F2-3909.
- `hw1`[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value `0b1110`.
- `hw2`[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value `0b101`.
- `hw2`[4] of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value `0b0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

T32 encoding	A32 encoding
op0	Bit[28] of the instruction encoding is 1 when cond is 0b1111.
op1	op0
op2	op1
op3	op2

F2.7.5 The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions

Restrictions on the use of PC or 0b1111 as a register specifier differ between the T32 and the A32 instruction sets, as described in:

- *T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier*.
- *A32 restrictions on the use of PC or 0b1111 as a register specifier* on page F2-3922.

T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier

The use of 0b1111 as a register specifier is not normally permitted in T32 instructions. When a value of 0b1111 is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the PC. This means branch tables can be placed in memory immediately after the instruction.

  Note

  Arm deprecates use of the PC as the base register in the STC instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no writeback), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the ADD and SUB instructions permit their source registers to be 0b1111 for the same purpose.
- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.
- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
  - Implicitly, for example, branch instructions.
  - Explicitly by a register specifier of 0b1111, for example 16-bit MOV (register) instructions.
  - Explicitly by using a register mask, for example LDM instructions.

  The address to branch to can be:
  - A loaded value, for example, RFE.
  - A register value, for example, BX.
  - The result of a calculation, for example, TBB or TBH.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The method of choosing the instruction set used after the branch can be:

— Similar to the LDR case, for example, LDM or BX.

— A fixed instruction set other than the one currently being used, for example, the immediate form of BLX.

— Unchanged, for example, branch instructions or 16-bit MOV (register) instructions.

— Set from the SPSR.T bit, for RFE and SUBS PC, LR, #imm8.

- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.
- If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is 0b1111, the instruction is a memory hint instead of a load operation.
- If the destination register specifier of an MRC instruction is 0b1111, bits[31:28] of the value transferred from the System register are written to the N, Z, C, and V Condition flags in the APSR, and bits[27:0] are discarded.

A32 restrictions on the use of PC or 0b1111 as a register specifier

In A32 instructions, the use of 0b1111 as a register specifier specifies the PC.

Many instructions are CONSTRAINED UNPREDICTABLE if they use 0b1111 as a register specifier. This is specified by pseudocode in the instruction description. Armv8-A constrains the resulting CONSTRAINED UNPREDICTABLE behavior, see *Using R15* on page K1-7607.

Note

Arm deprecates use of the PC as the base register in any store instruction.

F2.7.6 The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions

In the T32 and A32 instruction sets, Arm recommends that the use of 0b1101 as a register specifier specifies the SP.

Note

- The recommendation that the register specifier 0b1101 is only used to specify the SP applies to both the T32 and the A32 instruction sets.
- Despite this recommendation, T32 instructions that can access R13, or the SP, behave predictably in Armv8. This differs from Armv7, where many uses of R13 are defined as UNPREDICTABLE. For more information about these cases see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

F2.7.7 Modified immediate constants in T32 and A32 instructions

The following sections describe the encoding of modified immediate constants:

- *Modified immediate constants in T32 instructions* on page F2-3923.
- *Modified immediate constants in A32 instructions* on page F2-3924.
- *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F2-3925.
- *Modified immediate constants in T32 and A32 floating-point instructions* on page F2-3926.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Modified immediate constants in T32 instructions

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

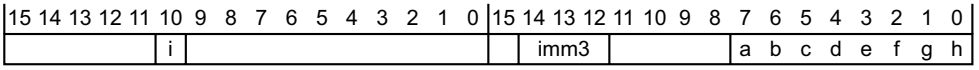


Table F2-2 shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

Table F2-2 Encoding of modified immediates in T32 data-processing instructions

i:imm3:a	<const> [a]
0000x	`00000000 00000000 00000000 abcdefgh`
0001x	`00000000 abcdefgh 00000000 abcdefgh` [b]
0010x	`abcdefgh 00000000 abcdefgh 00000000` [b]
0011x	`abcdefgh abcdefgh abcdefgh abcdefgh` [b]
01000	`1bcdefgh 00000000 00000000 00000000`
01001	`01bcdefg h0000000 00000000 00000000` [c]
01010	`001bcdef gh000000 00000000 00000000`
01011	`0001bcde fgh00000 00000000 00000000` [c]
.	.
.	. 8-bit values shifted to other positions
.	.
11101	`00000000 00000000 000001bc defgh000` [c]
11110	`00000000 00000000 0000001b cdefgh00`
11111	`00000000 00000000 00000001 bcdefgh0` [c]

a. This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

b. Arm deprecates using a modified immediate with abcdefgh == 00000000, and these cases are CONSTRAINED UNPREDICTABLE, see *UNPREDICTABLE cases in immediate constants in T32 data-processing instructions* on page K1-7610.

c. Not available in A32 instructions if `h` == 1.

Note

As the footnotes to Table F2-2 show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See *Modified immediate constants in A32 instructions* on page F2-3924 for the A32 values.

Carry out

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.

Operation of modified immediate constants, T32 instructions

For a T32 data-processing instruction, the `T32ExpandImm()` pseudocode function returns the value of the 32-bit immediate constant, calling `T32ExpandImm_C()` to evaluate the constant.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

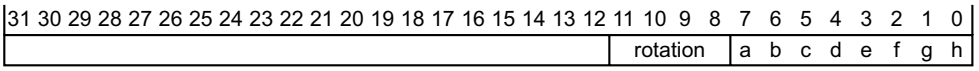

Table F2-3 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

Table F2-3 Encoding of modified immediates in A32 processing instructions

rotation	<const> [a]
0000	`00000000 00000000 00000000 abcdefgh`
0001	`gh000000 00000000 00000000 00abcdef`
0010	`efgh0000 00000000 00000000 0000abcd`
0011	`cdefgh00 00000000 00000000 000000ab`
0100	`abcdefgh 00000000 00000000 00000000`
. . .	. . . 8-bit values shifted to other even-numbered positions
1001	`00000000 00abcdef gh000000 00000000`
. . .	. . . 8-bit values shifted to other even-numbered positions
1110	`00000000 00000000 0000abcd efgh0000`
1111	`00000000 00000000 000000ab cdefgh00`

a. This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

Note

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See *Modified immediate constants in T32 instructions* on page F2-3923.

Carry out

A logical instruction with the rotation field set to `0b0000` does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

Constants with multiple encodings

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F2-3. For example, the constant `#3` must be encoded with (rotation, abcdefgh) == (`0b0000`, `0b00000011`), not (`0b0001`, `0b00001100`), (`0b0010`, `0b00110000`), or (`0b0011`, `0b11000000`).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

<byte> Is the numeric value of abcdefgh, in the range 0-255.

<rot> Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and Arm deprecates their use.

Operation of modified immediate constants, A32 instructions

For an A32 data-processing instruction, the A32ExpandImm() pseudocode function returns the value of the 32-bit immediate constant, calling A32ExpandImm_C() to evaluate the constant.

Modified immediate constants in T32 and A32 Advanced SIMD instructions

Table F2-4 shows the modified immediate constants available with Advanced SIMD instructions, and how they are encoded.

Table F2-4 Modified immediate values for Advanced SIMD instructions

op	cmode	Constant[a]	<dt>[b]	Notes
-	000x	00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh	I32	c
	001x	00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000	I32	c, d
	010x	00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000	I32	c, d
	011x	abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000	I32	c, d
	100x	00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh	I16	c
	101x	abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000	I16	c, d
	1100	00000000 00000000 abcdefgh 11111111 00000000 00000000 abcdefgh 11111111	I32	d, e
	1101	00000000 abcdefgh 11111111 11111111 00000000 abcdefgh 11111111 11111111	I32	d, e
0	1110	abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh	I8	f
	1111	aBbbbbbc defgh000 00000000 00000000 aBbbbbbc defgh000 00000000 00000000	F32	f, g
1	1110	aaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee ffffffff gggggggg hhhhhhhh	I64	f
	1111	UNDEFINED	-	-

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x0000000A0000000A.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, `VMOV.I64 D0, #0x8000000080000000` does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as `VMOV.I32 D0, #0x80000000`.

c. This constant is available for the `VBIC`, `VMOV`, `VMVN`, and `VORR` instructions.

d. CONSTRAINED UNPREDICTABLE if `abcdefgh == 0b00000000`, see *UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions* on page K1-7611. The required behavior is that these encodings produce an immediate constant of zero.

e. This constant is available for the `VMOV` and `VMVN` instructions only.

f. This constant is available for the `VMOV` instruction only.

g. In this entry, `B` = NOT(`b`). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = `UInt(a)`, exp = `UInt(NOT(b):c:d)-3` and mantissa = `(16+UInt(e:f:g:h))/16`.

Operation of modified immediate constants, Advanced SIMD instructions

For a T32 or A32 Advanced SIMD instruction that uses a modified immediate constant, the operation described by the `AdvSIMDExpandImm()` pseudocode function returns the value of the 64-bit immediate constant.

Modified immediate constants in T32 and A32 floating-point instructions

Table F2-5 shows the immediate constants available in the `VMOV` (immediate) floating-point instruction, and Table F2-6 shows the resulting floating-point values.

Table F2-5 Floating-point modified immediate constants

Data type	imm4H	imm4L	Constant [a]
F16	abcd	efgh	aBbbcdef gh000000
F32	abcd	efgh	aBbbbbbc defgh000 00000000 00000000
F64	abcd	efgh	aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000

a. In this column, `B` = NOT(`b`). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = `UInt(a)`, exp = `UInt(NOT(b):c:d)-3` and mantissa = `(16+UInt(e:f:g:h))/16`.

Table F2-6 Floating-point constant values

Operation of modified immediate constants, floating-point instructions

For a T32 or A32 floating-point instruction that uses a modified immediate constant, the operation described by the `VFPExpandImm()` pseudocode function returns the value of the immediate constant.

F2.8 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of A32 and T32 instructions, see:

- *Pseudocode description of conditional execution* on page F2-3910.
- *Pseudocode description of instruction-specified shifts and rotates* on page F2-3912

The following subsection gives additional pseudocode support functions for some of the instructions described in *Alphabetical list of T32 and A32 base instruction set instructions* on page F5-4068. See also *Pseudocode support for the banked register transfer instructions* on page F5-4780.

F2.8.1 Pseudocode description of operations for System register access instructions

The `AArch32.SysRegRead()` function obtains the word for an `MRC` instruction from the System register.

The `AArch32.SysRegRead64()` function obtains the two words for an `MRRC` instruction from the System register.

Note

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

The `AArch32.SysRegWrite()` procedure sends the word for an `MCR` instruction to the System register.

The `AArch32.SysRegWrite64()` procedure sends the two words for an `MCRR` instruction to the System register.

Note

The relative significance of `word2` and `word1` is IMPLEMENTATION DEFINED, but all uses within this manual treat `word2` as more significant than `word1`.

F2.8.2 Pseudocode details of system calls

The `AArch32.CallSupervisor()` pseudocode function generates a Supervisor Call exception. Valid execution of the `SVC` instruction calls this function.

The `AArch32.CallHypervisor()` pseudocode function generates an HVC exception. Valid execution of the `HVC` instruction calls this function.

F2.9 Additional information about Advanced SIMD and floating-point instructions

The following subsections give additional information about the Advanced SIMD and floating-point instructions:

- *Advanced SIMD and floating-point instruction syntax*.
- *The Advanced SIMD addressing mode*.
- *Advanced SIMD instruction modifiers* on page F2-3930.
- *Advanced SIMD operand shapes* on page F2-3930.
- *Data type specifiers* on page F2-3931.
- *Register specifiers* on page F2-3932.
- *Register lists* on page F2-3933.
- *Register encoding* on page F2-3933.
- *Advanced SIMD scalars* on page F2-3934.

Note

The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.

F2.9.1 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets.

Advanced SIMD and floating-point data-processing instructions use the following general format:

```
V{<modifier>}<operation>{<shape>}{<c>}{<q>}{.<dt>}  {<dest>,} <src1>, <src2>
```

All Advanced SIMD and floating-point instructions begin with a `V`. This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the `<operation>` field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The `<c>` and `<q>` fields are standard assembler syntax fields. For details see *Standard assembler syntax fields* on page F2-3908.

F2.9.2 The Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

`[<Rn>{:<align>}]`

The address is contained in general-purpose register Rn.

Rn is not updated by this instruction.

Encoded as Rm = `0b1111`.

If Rn is encoded as `0b1111`, the instruction is CONSTRAINED UNPREDICTABLE.

`[<Rn>{:<align>}]!`

The address is contained in general-purpose register Rn.

Rn is updated by this instruction: `Rn = Rn + transfer_size`

Encoded as Rm = `0b1101`.

`transfer_size` is the number of bytes transferred by the instruction. This means that, after the instruction is executed, Rn points to the address in memory immediately following the last address loaded from or stored to.

If Rn is encoded as `0b1111`, the instruction is CONSTRAINED UNPREDICTABLE.

This addressing mode can also be written as:

`[<Rn>{:align}], #<transfer_size>`

However, disassembly produces the `[<Rn>{:align}]!` form.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`[<Rn>{:<align>}], <Rm>`

The address is contained in general-purpose register `<Rn>`.

Rn is updated by this instruction: `Rn = Rn + Rm`

Encoded as Rm = Rm. Rm must not be encoded as `0b1111` or `0b1101`, the PC or the SP.

If Rn is encoded as `0b1111`, the instruction is CONSTRAINED UNPREDICTABLE.

The CONSTRAINED UNPREDICTABLE behavior of encodings where Rn is 0b1111 is described in the section: *Using R15 on page K1-7607*.

In all cases, `<align>` specifies an alignment, as specified by the individual instruction descriptions.

Previous versions of the manual used the `@` character for alignment. So, for example, the first format in this section was shown as `[<Rn>{@<align>}]`. Both `@` and `:` are supported. However, to ensure portability of code to assemblers that treat `@` as a comment character, `:` is preferred.

F2.9.3 Advanced SIMD instruction modifiers

The `<modifier>` field provides additional variants of some instructions. Table F2-7 provides definitions of the modifiers. Modifiers are not available for every instruction.

Table F2-7 Advanced SIMD instruction modifiers

<modifier>	Meaning
Q	The operation uses saturating arithmetic.
R	The operation performs rounding.
D	The operation doubles the result (before accumulation, if any).
H	The operation halves the result.

F2.9.4 Advanced SIMD operand shapes

The `<shape>` field provides additional variants of some instructions. Table F2-8 provides definitions of the shapes. Operand shapes are not available for every instruction.

Table F2-8 Advanced SIMD operand shapes

<shape>	Meaning	Typical register shape	
(none)	The operands and result are all the same width.	Dd, Dn, Dm	Qd, Qn, Qm
L	Long operation - result is twice the width of both operands	Qd, Dn, Dm	
N	Narrow operation - result is half the width of both operands	Dd, Qn, Qm	
W	Wide operation - result and first operand are twice the width of the second operand	Qd, Qn, Dm	

Note

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is `VADDQ.S32 q0, q1, q2`. This is not standard UAL, and Arm recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in Table F2-8.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F2.9.5 Data type specifiers

The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the <dt> field combined with the instruction shape. For information about data type formats see *Data types supported by the Advanced SIMD implementation* on page E1-3796.

In the instruction syntax descriptions in Chapter F2 *About the T32 and A32 Instruction Descriptions*, the <dt> field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, <type><size>.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:

  `VSUBW.I16.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`

- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:

  `VSUBW.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`

- Software can specify two data types, specifying the data types of the single operand and the result. For example:

  `VMOVN.I16.I32 D0, Q1` instead of `VMOVN.I32 D0, Q1`

- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in Table F2-9.

- Where an instruction does not require a data type, software can provide one.

- The `F32` data type can be abbreviated to `F`.

- The `F64` data type can be abbreviated to `D`.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

Table F2-9 Data type specification flexibility

Specified data type	Permitted more specific data types				
None	Any				
.I<size>	-	.S<size>	.U<size>	-	-
.8	.I8	.S8	.U8	.P8	-
.16	.I16	.S16	.U16	.P16	.F16
.32	.I32	.S32	.U32	-	.F32 or .F
.64	.I64	.S64	.U64	-	.F64 or .D

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

F2.9.6 Register specifiers

The <dest>, <src1>, and <src2> fields contain register specifiers, or in some cases scalar specifiers or register lists. Table F2-10 shows the register and scalar specifier formats that appear in the instruction descriptions.

If <dest> is omitted, it is the same as <src1>.

Table F2-10 Advanced SIMD and floating-point register specifier formats

<specifier>	Usual meaning [a]	Used in
<Qd>	A quadword destination register for the result vector.	Advanced SIMD
<Qn>	A quadword source register for the first operand vector.	Advanced SIMD
<Qm>	A quadword source register for the second operand vector.	Advanced SIMD
<Dd>	A doubleword destination register for the result vector.	Both
<Dn>	A doubleword source register for the first operand vector.	Both
<Dm>	A doubleword source register for the second operand vector.	Both
<Sd>	A singleword destination register for the result vector.	Floating-point
<Sn>	A singleword source register for the first operand vector.	Floating-point
<Sm>	A singleword source register for the second operand vector.	Floating-point
<Dd[x]>	A destination scalar for the result. Element x of vector <Dd>.	Advanced SIMD
<Dn[x]>	A source scalar for the first operand. Element x of vector <Dn>.	Both[b]
<Dm[x]>	A source scalar for the second operand. Element x of vector <Dm>.	Advanced SIMD
<Rt>	A general-purpose register, used for a source or destination address.	Both
<Rt2>	A general-purpose register, used for a source or destination address.	Both
<Rn>	A general-purpose register, used as a load or store base address.	Both
<Rm>	A general-purpose register, used as a post-indexed address source.	Both

a. In some instructions the roles of registers are different.

b. In the floating-point instructions, <Dn[x]> is used only in VMOV (scalar to general-purpose register), see *VMOV (scalar to general-purpose register)* on page F6-5145.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

F2.9.7 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F2-11 shows some register list formats, with examples of actual register lists corresponding to those formats.

Note

Register lists must not wrap around the end of the register bank.

Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example `{D0-D3}` instead of `{D0, D1, D2, D3}`.
- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example `{Q1, Q2}` instead of `{D2-D5}`.
- Where a register list contains only one register, the enclosing braces can be omitted, for example `VLD1.8 D0, [R0]` instead of `VLD1.8 {D0}, [R0]`.

Table F2-11 Example register lists

Format	Example	Alternative
`{<Dd>}`	`{D3}`	`D3`
`{<Dd>, <Dd+1>, <Dd+2>}`	`{D3, D4, D5}`	`{D3-D5}`
`{<Dd[x]>, <Dd+2[x]}`	`{D0[3], D2[3]}`	-
`{<Dd[]>}`	`{D7[]}`	`D7[]`

F2.9.8 Register encoding

An Advanced SIMD register is either:

- *Quadword*, meaning it is 128 bits wide.
- *Doubleword*, meaning it is 64 bits wide.

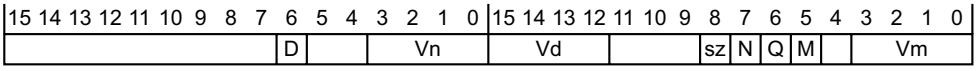
Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

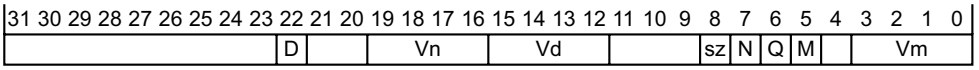
- Double-precision, meaning it is 64 bits wide.
- Single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:



The A32 instruction encoding of Advanced SIMD or floating-point registers is:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F2-12 shows the encodings for the registers.

Table F2-12 Encoding of register numbers

Register mnemonic	Usual usage	Register number encoded in[a]	Notes[a]	Used in
<Qd>	Destination (quadword)	D, Vd (bits[22, 15:13])	bit[12] == 0[b]	Advanced SIMD
<Qn>	First operand (quadword)	N, Vn (bits[7, 19:17])	bit[16] == 0[b]	Advanced SIMD
<Qm>	Second operand (quadword)	M, Vm (bits[5, 3:1])	bit[0] == 0[b]	Advanced SIMD
<Dd>	Destination (doubleword)	D, Vd (bits[22, 15:12])	-	Both
<Dn>	First operand (doubleword)	N, Vn (bits[7, 19:16])	-	Both
<Dm>	Second operand (doubleword)	M, Vm (bits[5, 3:0])	-	Both
<Sd>	Destination (single-precision)	Vd, D (bits[15:12, 22])	-	Floating-point
<Sn>	First operand (single-precision)	Vn, N (bits[19:16, 7])	-	Floating-point
<Sm>	Second operand (single-precision)	Vm, M (bits[3:0, 5])	-	Floating-point

a. Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.
b. If this bit is 1, the instruction is UNDEFINED.

F2.9.9 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F2-13 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, `Dm[x]` in a 32-bit context (0 <= `m` <= 15, 0 <= `x` <=1) is equivalent to `S[2m + x]`.

Table F2-13 Encoding of scalars in multiply instructions

Scalar mnemonic	Usual usage	Scalar size	Register specifier	Index specifier	Accessible registers
<Dm[x]>	Second operand	16-bit	Vm[2:0]	M, Vm[3]	D0-D7
		32-bit	Vm[3:0]	M	D0-D15

Chapter F3
T32 Instruction Set Encoding

This chapter describes the encoding of the T32 instruction set. It contains the following sections:

- *T32 instruction set encoding* on page F3-3936.
- *About the T32 Advanced SIMD and floating-point instructions and their encoding* on page F3-4003.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F3.1 T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- `0b11101`.
- `0b11110`.
- `0b11111`.

Otherwise, the halfword is a 16-bit instruction.

The T32 instruction encoding is:

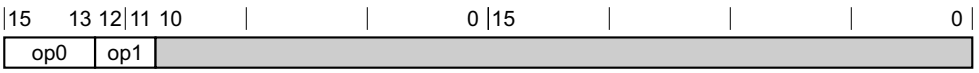

Table F3-1 Main encoding table for the T32 instruction set

F3.1.8 System register load/store and 64-bit move

This section describes the encoding of the System register load/store and 64-bit move group. The encodings in this section are decoded from *System register access, Advanced SIMD, and floating-point* on page F3-3953.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see *About the T32 Advanced SIMD and floating-point instructions and their encoding* on page F3-4003

F3.1.18 Advanced SIMD element or structure load/store

This section describes the encoding of the Advanced SIMD element or structure load/store group. The encodings in this section are decoded from *32-bit* on page F3-3947.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see *About the T32 Advanced SIMD and floating-point instructions and their encoding* on page F3-4003

Table F3-19 Encoding table for the Advanced SIMD element or structure load/store group

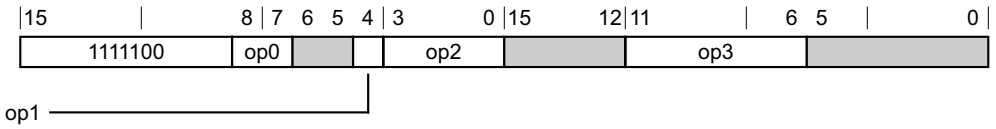
F3.1.19 Load/store single

This section describes the encoding of the Load/store single group. The encodings in this section are decoded from *32-bit* on page F3-3947.



This decode also imposes the constraint:

- `op0<1>:op1 != 10`.

Table F3-20 Encoding table for the Load/store single group

Decode fields				Decode group or instruction page
op0	op1	op2	op3

F3.2 About the T32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All T32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit T32 instruction decode structure. Table F3-23 shows these instruction groups, and where each group is decoded from the overall T32 decode structure:

Table F3-23 Advanced SIMD and floating-point instructions in the T32 decode structure

Advanced SIMD and floating-point instruction group	T32 decode is from
Advanced SIMD load/store and 64-bit move on page F3-3972	*System register access, Advanced SIMD, and floating-point* on page F3-3953
Floating-point data-processing on page F3-3958	*System register access, Advanced SIMD, and floating-point* on page F3-3953
Advanced SIMD and floating-point 32-bit move on page F3-3974	*System register access, Advanced SIMD, and floating-point* on page F3-3953
Advanced SIMD data-processing on page F3-3962	*System register access, Advanced SIMD, and floating-point* on page F3-3953
Advanced SIMD element or structure load/store on page F3-3985	*32-bit* on page F3-3947

Chapter F4
A32 Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

- *A32 instruction set encoding* on page F4-4006.
- *About the A32 Advanced SIMD and floating-point instructions and their encoding* on page F4-4065.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

F4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is either a single 32-bit word in that stream.

Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the `cond` field. For more information see *The Condition code field in A32 instruction encodings* on page F2-3910. This applies to all instructions except those with the `cond` field equal to `0b111`.

The behavior of an attempt to execute an unallocated instruction is described in *UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space* on page F2-3916.

For more information on A32 instruction encodings see Chapter F2 *About the T32 and A32 Instruction Descriptions*.

The A32 instruction encoding is:

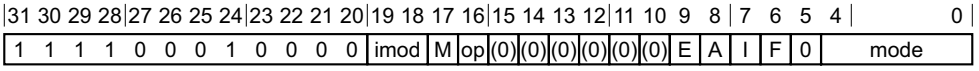
Table F4-18 Encoding table for the Miscellaneous group (continued)

Decode fields		Decode group or instruction page	Architecture version
op0	op1		
100xx	0011	Unallocated.	-
100xx	0x10	Unallocated.	-
100xx	1x1x	Unallocated.	-
101xx	-	Unallocated.	-
11xxx	-	Unallocated.	-

The behavior of the CONSTRAINED UNPREDICTABLE encodings in this table is described in *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings* on page K1-7618.

Change Process State

This section describes the encoding of the Change Process State instruction class. The encodings in this section are decoded from *Miscellaneous* on page F4-4048.



Decode fields				Instruction page
imod	M	op	mode	
-	-	1	0xxxx	SETEND
-	-	0	-	CPS, CPSID, CPSIE
-	-	1	1xxxx	Unallocated.

F4.1.20 Advanced SIMD data-processing

This section describes the encoding of the Advanced SIMD data-processing group. The encodings in this section are decoded from *Unconditional instructions* on page F4-4048.

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see *About the A32 Advanced SIMD and floating-point instructions and their encoding* on page F4-4065

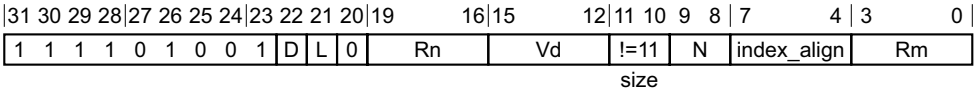
Advanced SIMD load/store single structure to one lane

This section describes the encoding of the Advanced SIMD load/store single structure to one lane instruction class. The encodings in this section are decoded from *Advanced SIMD element or structure load/store* on page F4-4061.



Decode fields			Instruction page
L	size	N	
0	00	00	VST1 (single element from one lane) - *A1* on page F6-5383
0	00	01	VST2 (single 2-element structure from one lane) - *A1* on page F6-5396

F4.2 About the A32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All A32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit A32 instruction decode structure. Table F4-24 shows these instruction groups, and where each group is decoded from the overall A32 decode structure:

Table F4-24 Advanced SIMD and floating-point instructions in the A32 decode structure

Advanced SIMD and floating-point instruction group	A32 decode is from
Advanced SIMD load/store and 64-bit move on page F4-4044	*System register access, Advanced SIMD, floating-point, and Supervisor call* on page F4-4034
Floating-point data-processing on page F4-4039	*System register access, Advanced SIMD, floating-point, and Supervisor call* on page F4-4034
Advanced SIMD and floating-point 32-bit move on page F4-4046	*System register access, Advanced SIMD, floating-point, and Supervisor call* on page F4-4034
Advanced SIMD data-processing on page F4-4049	*Unconditional instructions* on page F4-4048
Advanced SIMD element or structure load/store on page F4-4061	*Unconditional instructions* on page F4-4048

Chapter F5
T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Alphabetical list of T32 and A32 base instruction set instructions* on page F5-4068.
- *Encoding and use of banked register transfer instructions* on page F5-4777.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

F5.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see *Format of instruction descriptions* on page F2-3904.

This section is formatted so that each instruction description starts on a new page.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

F5.1.1 ADC, ADCS (immediate)

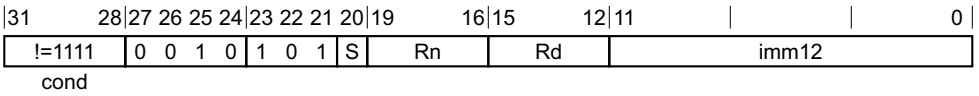
Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



ADC variant

Applies when S == 0.

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ADCS variant

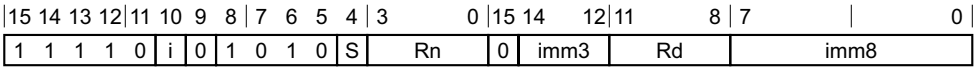
Applies when S == 1.

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

T1



ADC variant

Applies when S == 0.

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ADCS variant

Applies when S == 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 || n == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Non-Confidential

F5.1.2 ADC, ADCS (register)

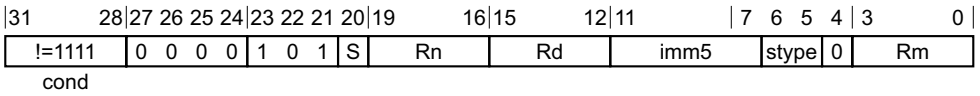
Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



ADC, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADC, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

ADCS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADCS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

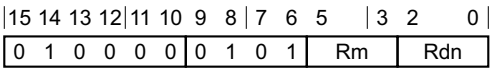
```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1



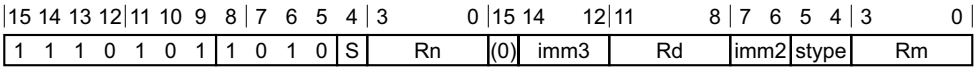
T1 variant

```
ADC<c>{<q>} {<Rdn>,} <Rdn>, <Rm> // Inside IT block
ADCS{<q>} {<Rdn>,} <Rdn>, <Rm> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



ADC, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADC, shift or rotate by value variant

Applies when `S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
ADC<c>.W {<Rd>,} <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ADC{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

ADCS, rotate right with extend variant

Applies when `S == 1 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADCS, shift or rotate by value variant

Applies when `S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
ADCS.W {<Rd>,} <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ADCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

LSL	when stype = 00
LSR	when stype = 01
ASR	when stype = 10
ROR	when stype = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.
- Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
else
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

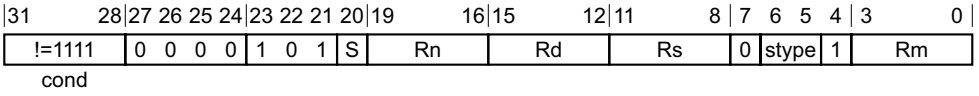
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.3 ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1



Flag setting variant

Applies when `S == 1`.

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when `S == 0`.

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.

`<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL`	when `stype = 00`
`LSR`	when `stype = 01`
`ASR`	when `stype = 10`
`ROR`	when `stype = 11`

`<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

F5.1.4 ADD, ADDS (immediate)

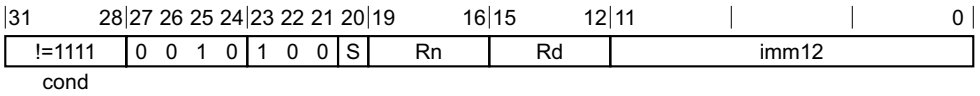
Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



ADD variant

Applies when S == 0 && Rn != 11x1.

```
ADD{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ADDS variant

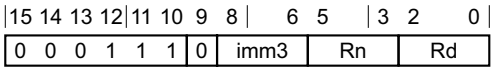
Applies when S == 1 && Rn != 1101.

```
ADDS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
if Rn == '1111' && S == '0' then SEE "ADR";
if Rn == '1101' then SEE "ADD (SP plus immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

T1



T1 variant

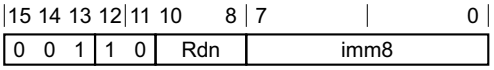
```
ADD<c>{<q>} <Rd>, <Rn>, #<imm3> // Inside IT block
ADDS{<q>} <Rd>, <Rn>, #<imm3> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rd);  n = UInt(Rn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm3, 32);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T2



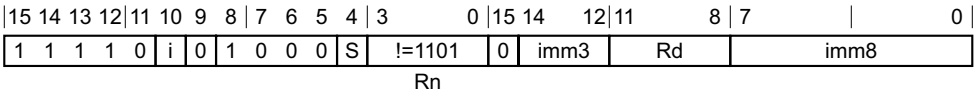
T2 variant

```
ADD<c>{<q>} <Rdn>, #<imm8> // Inside IT block, and <Rdn>, <imm8> can be represented in T1
ADD<c>{<q>} {<Rdn>,} <Rdn>, #<imm8> // Inside IT block, and <Rdn>, <imm8> cannot be represented in T1
ADDS{<q>} <Rdn>, #<imm8> // Outside IT block, and <Rdn>, <imm8> can be represented in T1
ADDS{<q>} {<Rdn>,} <Rdn>, #<imm8> // Outside IT block, and <Rdn>, <imm8> cannot be represented in T1
```

Decode for this encoding

```
d = UInt(Rdn);  n = UInt(Rdn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);
```

T3



ADD variant

Applies when `S == 0`.

```
ADD<c>.W {<Rd>,} <Rn>, #<const> // Inside IT block, and <Rd>, <Rn>, <const> can be represented in T1 or
T2
ADD{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ADDS variant

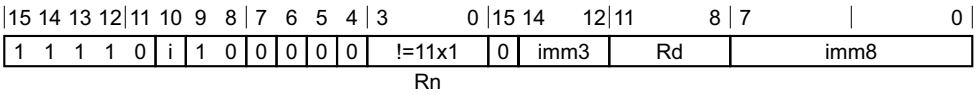
Applies when `S == 1 && Rd != 1111`.

```
ADDS.W {<Rd>,} <Rn>, #<const> // Outside IT block, and <Rd>, <Rn>, <const> can be represented in T1 or T2
ADDS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "CMN (immediate)";
if Rn == '1101' then SEE "ADD (SP plus immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

T4



T4 variant

```
ADD{<c>}{<q>} {<Rd>,} <Rn>, #<imm12> // <imm12> cannot be represented in T1, T2, or T3
ADDW{<c>}{<q>} {<Rd>,} <Rn>, #<imm12> // <imm12> can be represented in T1, T2, or T3
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if Rn == '1111' then SEE "ADR";
if Rn == '1101' then SEE "ADD (SP plus immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;   // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rdn>` Is the general-purpose source and destination register, encoded in the "Rdn" field.

`<imm8>` Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction.

For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

`<Rn>` For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate). If the PC is used, see ADR.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate).

`<imm3>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.

`<imm12>` Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

`<const>` For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T3: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the `ADDW` syntax). Encoding T1 is preferred to encoding T2 if `<Rd>` is specified and encoding T2 is preferred to encoding T1 if `<Rd>` is omitted.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        (result, nzcv) = AddWithCarry(R[n], imm32, '0');
        if d == 15 then          // Can only occur for A32 encoding
            if setflags then
                ALUExceptionReturn(result);
            else
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
                ALUWritePC(result);
            else
                R[d] = result;
                if setflags then
                    PSTATE.<N,Z,C,V> = nzcv;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        (result, nzcv) = AddWithCarry(R[n], imm32, '0');
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Non-Confidential

F5.1.5 ADD, ADDS (register)

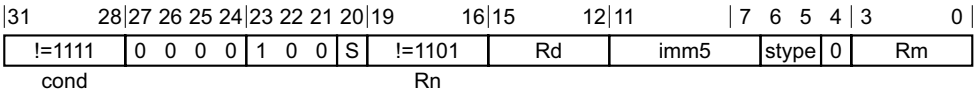
Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



ADD, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADD, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

ADDS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
ADDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADDS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

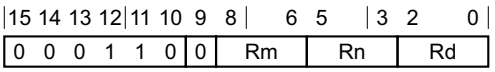
```
ADDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if Rn == '1101' then SEE "ADD (SP plus register)";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1



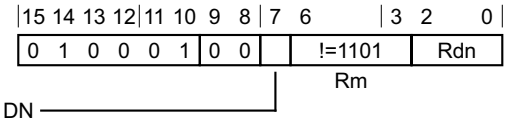
T1 variant

```
ADD<c>{<q>} <Rd>, <Rn>, <Rm> // Inside IT block
ADDS{<q>} {<Rd>,} <Rn>, <Rm> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



T2 variant

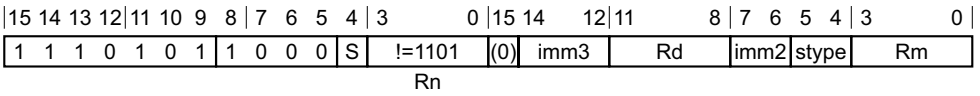
Applies when `!(DN == 1 && Rdn == 101)`.

```
ADD<c>{<q>} <Rdn>, <Rm> // Preferred syntax, Inside IT block
ADD{<c>}{<q>} {<Rdn>,} <Rdn>, <Rm>
```

Decode for this encoding

```
if (DN:Rdn) == '1101' || Rm == '1101' then SEE "ADD (SP plus register)";
d = UInt(DN:Rdn);  n = d;  m = UInt(Rm);  setflags = FALSE;  (shift_t, shift_n) = (SRType_LSL, 0);
if n == 15 && m == 15 then UNPREDICTABLE;
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

T3



ADD, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADD, shift or rotate by value variant

Applies when `S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
ADD<c>.W {<Rd>,} <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ADD{<c>}.W {<Rd>,} <Rn>, <Rm> // <Rd> == <Rn>, and <Rd>, <Rn>, <Rm> can be represented in T2
ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ADDS, rotate right with extend variant

Applies when S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11.

```
ADDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ADDS, shift or rotate by value variant

Applies when S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11) && Rd != 1111.

```
ADDS.W {<Rd>,} <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1 or T2
ADDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "CMN (register)";
if Rn == '1101' then SEE "ADD (SP plus register)";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rdn> Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

The assembler language allows <Rdn> to be specified once or twice in the assembler syntax. When used inside an IT block, and <Rdn> and <Rm> are in the range R0 to R7, <Rdn> must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when <Rdn> is specified once or twice.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

When used inside an IT block, <Rd> must be specified. When used outside an IT block, <Rd> is optional, and:

- If omitted, this register is the same as <Rn>.
- If present, encoding T1 is preferred to encoding T2.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see ADD, ADDS (SP plus register).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus register).

`<Rm>` For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field.

For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL` when `stype = 00`

`LSR` when `stype = 01`

`ASR` when `stype = 10`

`ROR` when `stype = 11`

`<amount>` For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Inside an IT block, if `ADD<c> <Rd>, <Rn>, <Rd>` cannot be assembled using encoding T1, it is assembled using encoding T2 as though `ADD<c> <Rd>, <Rn>` had been written. To prevent this happening, use the `.W` qualifier.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

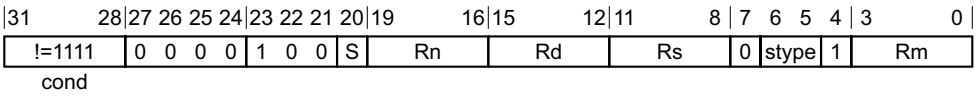
Non-Confidential

F5.1.6 ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1



Flag setting variant

Applies when `S == 1`.

```
ADDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when `S == 0`.

```
ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.

`<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL`	when `stype = 00`
`LSR`	when `stype = 01`
`ASR`	when `stype = 10`
`ROR`	when `stype = 11`

`<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Non-Confidential

F5.1.7 ADD, ADDS (SP plus immediate)

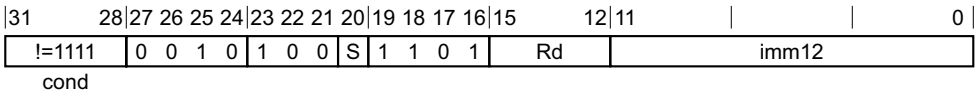
Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



ADD variant

Applies when `S == 0`.

```
ADD{<c>}{<q>} {<Rd>,} SP, #<const>
```

ADDS variant

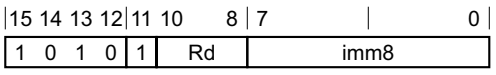
Applies when `S == 1`.

```
ADDS{<c>}{<q>} {<Rd>,} SP, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

T1



T1 variant

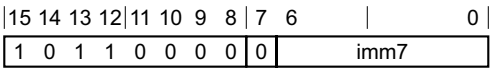
```
ADD{<c>}{<q>} <Rd>, SP, #<imm8>
```

Decode for this encoding

```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm8:'00', 32);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T2



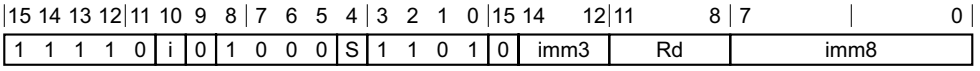
T2 variant

```
ADD{<c>}{<q>} {SP,} SP, #<imm7>
```

Decode for this encoding

```
d = 13;  setflags = FALSE;  imm32 = ZeroExtend(imm7:'00', 32);
```

T3



ADD variant

Applies when `S == 0`.

```
ADD{<c>}.W {<Rd>,} SP, #<const> // <Rd>, <const> can be represented in T1 or T2
ADD{<c>}{<q>} {<Rd>,} SP, #<const>
```

ADDS variant

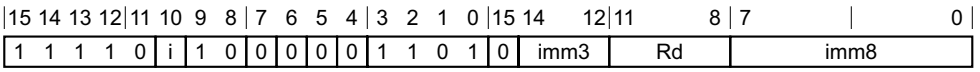
Applies when `S == 1 && Rd != 1111`.

```
ADDS{<c>}{<q>} {<Rd>,} SP, #<const>
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "CMN (immediate)";
d = UInt(Rd);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 && !setflags then UNPREDICTABLE;
```

T4



T4 variant

```
ADD{<c>}{<q>} {<Rd>,} SP, #<imm12> // <imm12> cannot be represented in T1, T2, or T3
ADDW{<c>}{<q>} {<Rd>,} SP, #<imm12> // <imm12> can be represented in T1, T2, or T3
```

Decode for this encoding

```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`SP,` Is the stack pointer.

`<imm7>` Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

`<imm8>` Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

`<imm12>` Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

`<const>` For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T3: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, imm32, '0');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F5.1.8 ADD, ADDS (SP plus register)

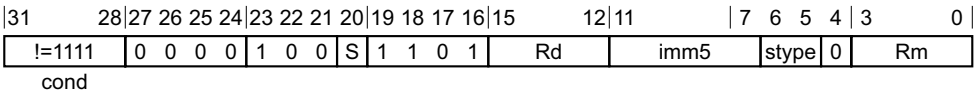
Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



ADD, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
ADD{<c>}{<q>} {<Rd>,} SP, <Rm> , RRX
```

ADD, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
ADD{<c>}{<q>} {<Rd>,} SP, <Rm> {, <shift> #<amount>}
```

ADDS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
ADDS{<c>}{<q>} {<Rd>,} SP, <Rm> , RRX
```

ADDS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

```
ADDS{<c>}{<q>} {<Rd>,} SP, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

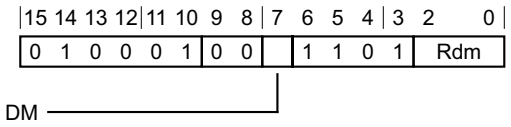
T1



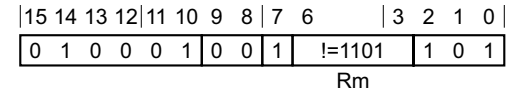
T1 variant

```
ADD{<c>}{<q>} {<Rdm>,} SP, <Rdm>
```

Decode for this encoding

```
d = UInt(DM:Rdm);  m = UInt(DM:Rdm);  setflags = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

T2



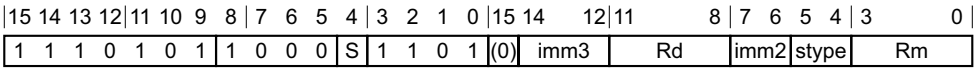
T2 variant

```
ADD{<c>}{<q>} {SP,} SP, <Rm>
```

Decode for this encoding

```
if Rm == '1101' then SEE "encoding T1";
d = 13;  m = UInt(Rm);  setflags = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

T3



ADD, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
ADD{<c>}{<q>} {<Rd>,} SP, <Rm>, RRX
```

ADD, shift or rotate by value variant

Applies when `S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
ADD{<c>}.W {<Rd>,} SP, <Rm> // <Rd>, <Rm> can be represented in T1 or T2
ADD{<c>}{<q>} {<Rd>,} SP, <Rm> {, <shift> #<amount>}
```

ADDS, rotate right with extend variant

Applies when `S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11`.

```
ADDS{<c>}{<q>} {<Rd>,} SP, <Rm>, RRX
```

ADDS, shift or rotate by value variant

Applies when `S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11) && Rd != 1111`.

```
ADDS{<c>}{<q>} {<Rd>,} SP, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "CMN (register)";
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if (d == 15 && !setflags) || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`SP,` Is the stack pointer.

`<Rdm>` Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

`<Rm>` For encoding A1 and T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL`	when `stype = 00`
`LSR`	when `stype = 01`
`ASR`	when `stype = 10`
`ROR`	when `stype = 11`

`<amount>` For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

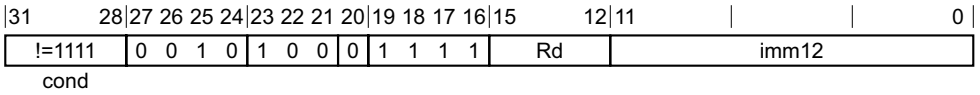
F5.1.9 ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias

This instruction is a pseudo-instruction of the ADR instruction. This means that:

- The encodings in this description are named to match the encodings of ADR.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of ADR gives the operational pseudocode for this instruction.

A1



A1 variant

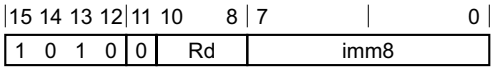
```
ADD{<c>}{<q>} <Rd>, PC, #<const>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is never the preferred disassembly.

T1



T1 variant

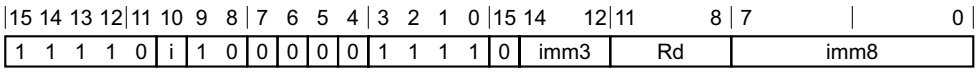
```
ADD{<c>}{<q>} <Rd>, PC, #<imm8>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is never the preferred disassembly.

T3



T3 variant

```
ADDW{<c>}{<q>} <Rd>, PC, #<imm12> // <Rd>, <imm12> can be represented in T1
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is never the preferred disassembly.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
ADD{<c>}{<q>} <Rd>, PC, #<imm12>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is never the preferred disassembly.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

For encoding T1 and T3: is the general-purpose destination register, encoded in the "Rd" field.

`<label>` For encoding A1: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding A1 is used, with `imm32` equal to the offset.

If the offset is negative, encoding A2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of `imm32`.

Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions* on page F2-3924.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T3: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding T3 is used, with `imm32` equal to the offset.

If the offset is negative, encoding T2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of `imm32`.

Permitted values of the size of the offset are 0-4095.

`<imm8>` Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

`<imm12>` Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

`<const>` An immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

Operation for all encodings

The description of ADR gives the operational pseudocode for this instruction.

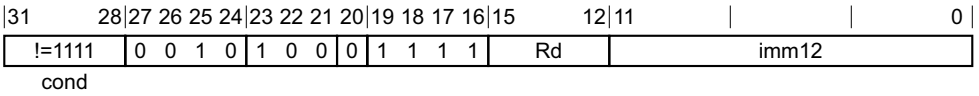
Non-Confidential

F5.1.10 ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

This instruction is used by the pseudo-instructions ADD (immediate, to PC) and SUB (immediate, from PC). The pseudo-instruction is never the preferred disassembly.

A1



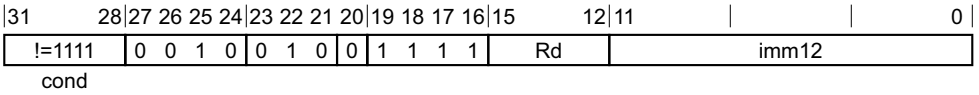
A1 variant

```
ADR{<c>}{<q>} <Rd>, <label>
```

Decode for this encoding

```
d = UInt(Rd);  imm32 = A32ExpandImm(imm12);  add = TRUE;
```

A2



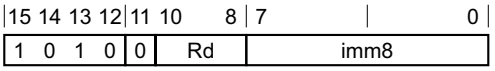
A2 variant

```
ADR{<c>}{<q>} <Rd>, <label>
```

Decode for this encoding

```
d = UInt(Rd);  imm32 = A32ExpandImm(imm12);  add = FALSE;
```

T1



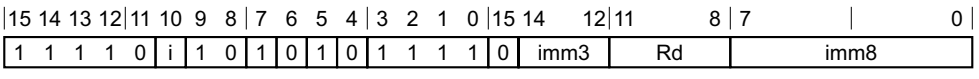
T1 variant

```
ADR{<c>}{<q>} <Rd>, <label>
```

Decode for this encoding

```
d = UInt(Rd);  imm32 = ZeroExtend(imm8:'00', 32);  add = TRUE;
```

T2



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

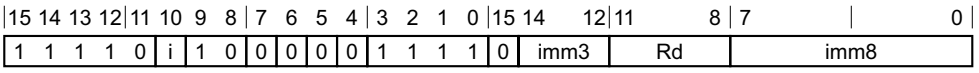
T2 variant

```
ADR{<c>}{<q>} <Rd>, <label>
```

Decode for this encoding

```
d = UInt(Rd);  imm32 = ZeroExtend(i:imm3:imm8, 32);  add = FALSE;
if d == 15 then UNPREDICTABLE;     // Armv8-A removes UNPREDICTABLE for R13
```

T3



T3 variant

```
ADR{<c>}.W <Rd>, <label> // <Rd>, <label> can be presented in T1
ADR{<c>}{<q>} <Rd>, <label>
```

Decode for this encoding

```
d = UInt(Rd);  imm32 = ZeroExtend(i:imm3:imm8, 32);  add = TRUE;
if d == 15 then UNPREDICTABLE;   // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Alias conditions

Alias or pseudo-instruction	of variant	is preferred when
ADD (immediate, to PC)	-	Never
SUB (immediate, from PC)	T2	`i:imm3:imm8 == '000000000000'`
SUB (immediate, from PC)	A2	`imm12 == '000000000000'`

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1 and A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

For encoding T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

`<label>` For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding A1 is used, with `imm32` equal to the offset.

If the offset is negative, encoding A2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of `imm32`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions* on page F2-3924.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding T3 is used, with `imm32` equal to the offset.

If the offset is negative, encoding T2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of `imm32`.

Permitted values of the size of the offset are 0-4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then          // Can only occur for A32 encodings
        ALUWritePC(result);
    else
        R[d] = result;
```

F5.1.11 AND, ANDS (immediate)

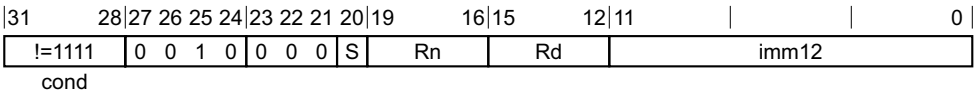
Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



AND variant

Applies when S == 0.

```
AND{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ANDS variant

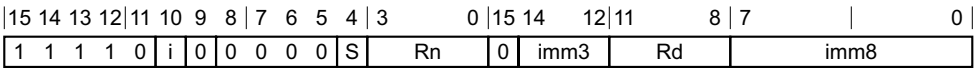
Applies when S == 1.

```
ANDS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1



AND variant

Applies when S == 0.

```
AND{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ANDS variant

Applies when S == 1 && Rd != 1111.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
ANDS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "TST (immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ANDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

`<Rn>` For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

`<const>` For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

F5.1.12 AND, ANDS (register)

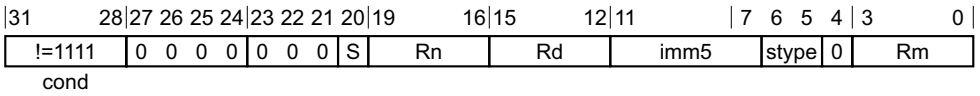
Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



AND, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
AND{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

AND, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
AND{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

ANDS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
ANDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ANDS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

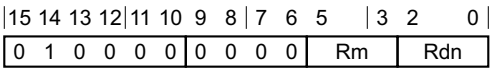
```
ANDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1



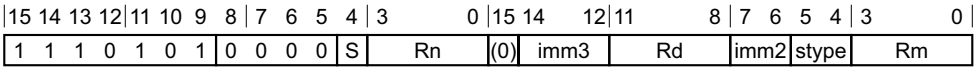
T1 variant

```
AND<c>{<q>} {<Rdn>,} <Rdn>, <Rm> // Inside IT block
ANDS{<q>} {<Rdn>,} <Rdn>, <Rm> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



AND, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
AND{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

AND, shift or rotate by value variant

Applies when `S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
AND<c>.W {<Rd>,} <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
AND{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

ANDS, rotate right with extend variant

Applies when `S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11`.

```
ANDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

ANDS, shift or rotate by value variant

Applies when `S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11) && Rd != 1111`.

```
ANDS.W {<Rd>,} <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ANDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "TST (register)";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rdn>` Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the ANDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

`<Rn>` For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL`	when `stype = 00`
`LSR`	when `stype = 01`
`ASR`	when `stype = 10`
`ROR`	when `stype = 11`

`<amount>` For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if `ANDS <Rd>, <Rn>, <Rd>` has `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `ANDS <Rd>, <Rn>` had been written.
- Inside an IT block, if `AND<c> <Rd>, <Rn>, <Rd>` has `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `AND<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the `.W` qualifier.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
else
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

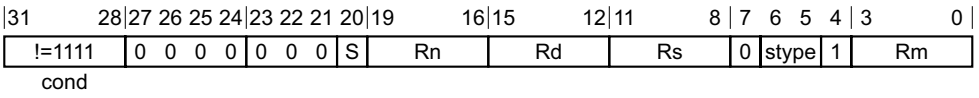
F5.1.13 AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1



Flag setting variant

Applies when `S == 1`.

```
ANDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when `S == 0`.

```
AND{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.

`<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- `LSL` when `stype = 00`
- `LSR` when `stype = 01`
- `ASR` when `stype = 10`
- `ROR` when `stype = 11`

`<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

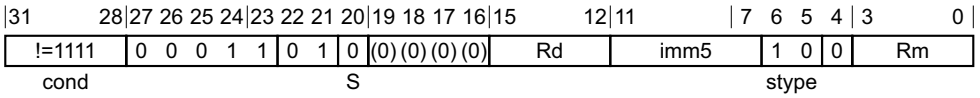
F5.1.14 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

A1



MOV, shift or rotate by value variant

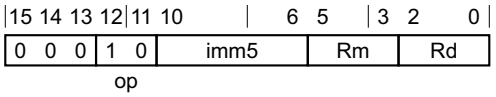
```
ASR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

T2



T2 variant

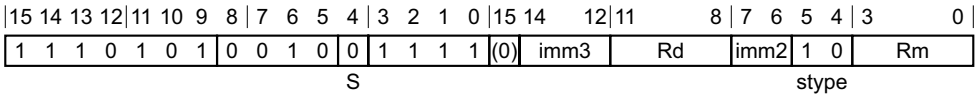
```
ASR<c>{<q>} {<Rd>,} <Rm>, #<imm> // Inside IT block
```

is equivalent to

```
MOV<c>{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is the preferred disassembly when `InITBlock()`.

T3



MOV, shift or rotate by value variant

```
ASR<c>.W {<Rd>,} <Rm>, #<imm> // Inside IT block, and <Rd>, <Rm>, <imm> can be represented in T2
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

```
ASR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

`<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

`<imm>` For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

Operation for all encodings

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

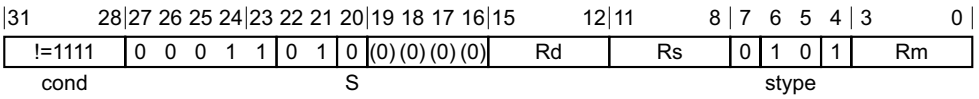
F5.1.15 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

A1



Not flag setting variant

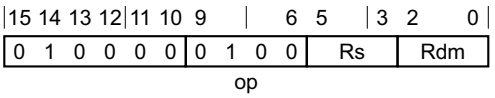
```
ASR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>
```

and is always the preferred disassembly.

T1



Arithmetic shift right variant

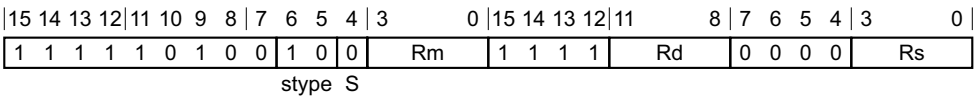
```
ASR<c>{<q>} {<Rdm>,} <Rdm>, <Rs> // Inside IT block
```

is equivalent to

```
MOV<c>{<q>} <Rdm>, <Rdm>, ASR <Rs>
```

and is the preferred disassembly when `InITBlock()`.

T2



Not flag setting variant

```
ASR<c>.W {<Rd>,} <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

and is always the preferred disassembly.

```
ASR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>
```

and is always the preferred disassembly.

Assembler symbols

`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rdm>`	Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
`<Rd>`	Is the general-purpose destination register, encoded in the "Rd" field.
`<Rm>`	Is the first general-purpose source register, encoded in the "Rm" field.
`<Rs>`	Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation for all encodings

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

F5.1.16 ASRS (immediate)

Arithmetic Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

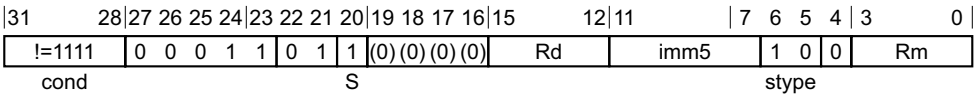
The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

A1



MOVS, shift or rotate by value variant

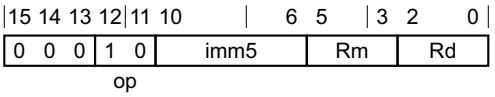
```
ASRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

T2



T2 variant

```
ASRS{<q>} {<Rd>,} <Rm>, #<imm> // Outside IT block
```

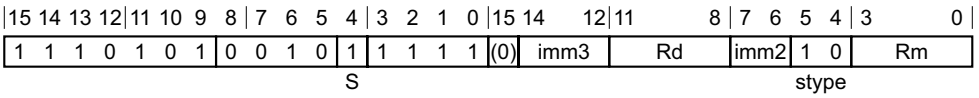
is equivalent to

```
MOVS{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is the preferred disassembly when `!InITBlock()`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T3



MOVS, shift or rotate by value variant

```
ASRS.W {<Rd>,} <Rm>, #<imm> // Outside IT block, and <Rd>, <Rm>, <imm> can be represented in T2
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

```
ASRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

`<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

`<imm>` For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

T3 variant

```
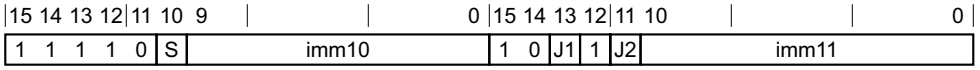
B<c>.W <label> // Not permitted in IT block, and <label> can be represented in T1
B<c>{<q>} <label> // Not permitted in IT block
```

Decode for this encoding

```
if cond<3:1> == '111' then SEE "Related encodings";
imm32 = SignExtend(S:J2:J1:imm6:imm11:'0', 32);
if InITBlock() then UNPREDICTABLE;
```

T4



T4 variant

```
B{<c>}.W <label> // <label> can be represented in T2
B{<c>}{<q>} <label>
```

Decode for this encoding

```
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Branches and miscellaneous control* on page F3-3979.

Assembler symbols

<c> For encoding A1, T2 and T4: see *Standard assembler syntax fields* on page F2-3908.

For encoding T1: see *Standard assembler syntax fields* on page F2-3908. Must not be AL or omitted.

For encoding T3: see *Standard assembler syntax fields* on page F2-3908. <c> must not be AL or omitted.

<q> See *Standard assembler syntax fields* on page F2-3908.

<label> For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset.

Permitted offsets are multiples of 4 in the range –33554432 to 33554428.

For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –256 to 254.

For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –2048 to 2046.

For encoding T3: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset.

Permitted offsets are even numbers in the range –1048576 to 1048574.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For encoding T4: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset.

Permitted offsets are even numbers in the range –16777216 to 16777214.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32, BranchType_DIR);
```

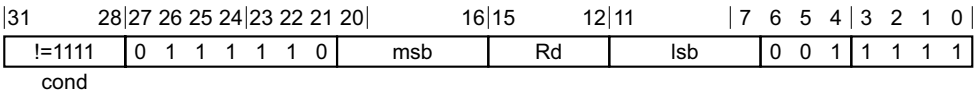
F5.1.19 BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

A1



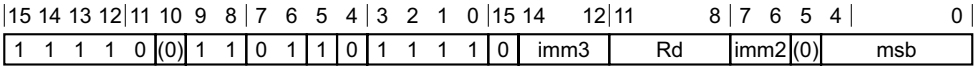
A1 variant

```
BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>
```

Decode for this encoding

```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>
```

Decode for this encoding

```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(imm3:imm2);
if d == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c>	See *Standard assembler syntax fields* on page F2-3908.
<q>	See *Standard assembler syntax fields* on page F2-3908.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<lsb>	For encoding A1: is the least significant bit to be cleared, in the range 0 to 31, encoded in the "lsb" field. For encoding T1: is the least significant bit that is to be cleared, in the range 0 to 31, encoded in the "imm3:imm2" field.
<width>	Is the number of bits to be cleared, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = Replicate('0', msbit-lsbit+1);
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

F5.1.21 BIC, BICS (immediate)

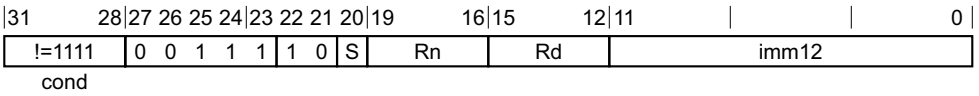
Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



BIC variant

Applies when S == 0.

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

BICS variant

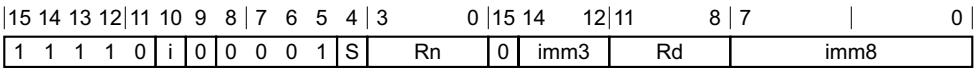
Applies when S == 1.

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1



BIC variant

Applies when S == 0.

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

BICS variant

Applies when S == 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 || n == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the BICS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F5.1.22 BIC, BICS (register)

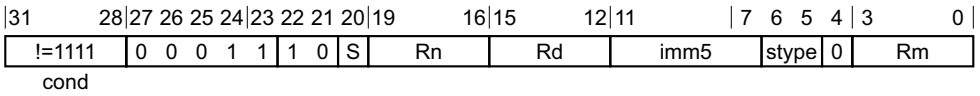
Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



BIC, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

BIC, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

BICS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

BICS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

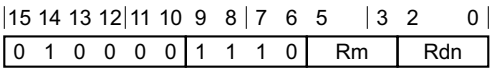
Non-Confidential

T1



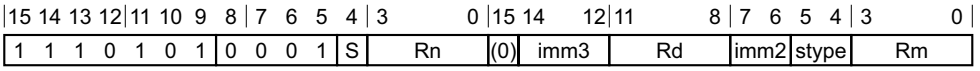
T1 variant

```
BIC<c>{<q>} {<Rdn>,} <Rdn>, <Rm> // Inside IT block
BICS{<q>} {<Rdn>,} <Rdn>, <Rm> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



BIC, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

BIC, shift or rotate by value variant

Applies when `S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
BIC<c>.W {<Rd>,} <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

BICS, rotate right with extend variant

Applies when `S == 1 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

BICS, shift or rotate by value variant

Applies when `S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
BICS.W {<Rd>,} <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the BICS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

LSL	when stype = 00
LSR	when stype = 01
ASR	when stype = 10
ROR	when stype = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

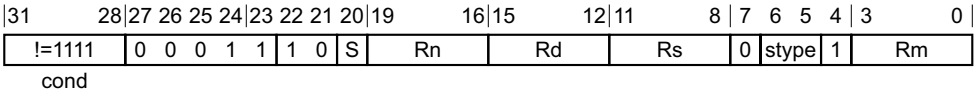
F5.1.23 BIC, BICS (register-shifted register)

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1



Flag setting variant

Applies when `S == 1`.

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when `S == 0`.

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.

`<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- `LSL` when `stype = 00`
- `LSR` when `stype = 01`
- `ASR` when `stype = 10`
- `ROR` when `stype = 11`

`<Rs>` Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Non-Confidential

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

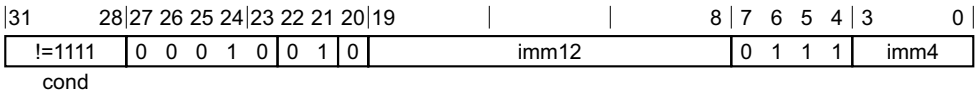
F5.1.24 BKPT

Breakpoint causes a Breakpoint Instruction exception.

Breakpoint is always unconditional, even when inside an IT block.

A1



A1 variant

```
BKPT{<q>} {#}<imm>
```

Decode for this encoding

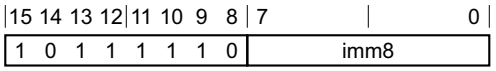
```
imm16 = imm12:imm4;
if cond != '1110' then UNPREDICTABLE;  // BKPT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1



T1 variant

```
BKPT{<q>} {#}<imm>
```

Decode for this encoding

```
imm16 = ZeroExtend(imm8, 16);
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<q> See *Standard assembler syntax fields* on page F2-3908. An `BKPT` instruction must be unconditional.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<imm>` For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

Operation for all encodings

```
EncodingSpecificOperations();
AArch32.SoftwareBreakpoint(imm16);
```

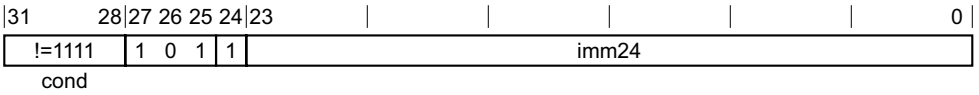
Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.25 BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address, and setting LR to the return address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, setting LR to the return address, and changes the instruction set from A32 to T32, or from T32 to A32.

A1



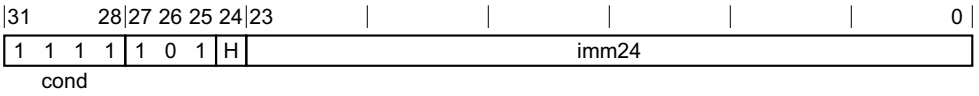
A1 variant

```
BL{<c>}{<q>} <label>
```

Decode for this encoding

```
imm32 = SignExtend(imm24:'00', 32);  targetInstrSet = InstrSet_A32;
```

A2



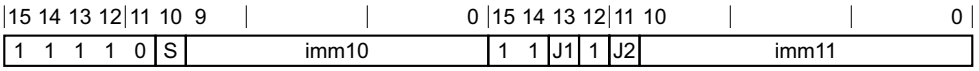
A2 variant

```
BLX{<c>}{<q>} <label>
```

Decode for this encoding

```
imm32 = SignExtend(imm24:H:'0', 32);  targetInstrSet = InstrSet_T32;
```

T1



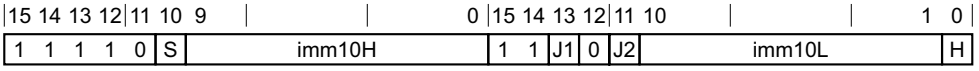
T1 variant

```
BL{<c>}{<q>} <label>
```

Decode for this encoding

```
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
targetInstrSet = InstrSet_T32;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

T2



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T2 variant

```
BLX{<c>}{<q>} <label>
```

Decode for this encoding

```
if H == '1' then UNDEFINED;
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10H:imm10L:'00', 32);
targetInstrSet = InstrSet_A32;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> For encoding A1, T1 and T2: see *Standard assembler syntax fields* on page F2-3908.

For encoding A2: see *Standard assembler syntax fields* on page F2-3908. <c> must be AL or omitted.

<q> See *Standard assembler syntax fields* on page F2-3908.

<label> For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset.

Permitted offsets are multiples of 4 in the range –33554432 to 33554428.

For encoding A2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.

Permitted offsets are even numbers in the range –33554432 to 33554430.

For encoding T1: the label of the instruction that is to be branched to.

The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset.

Permitted offsets are even numbers in the range –16777216 to 16777214.

For encoding T2: the label of the instruction that is to be branched to.

The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.

Permitted offsets are multiples of 4 in the range –16777216 to 16777212.

Operation for all encodings

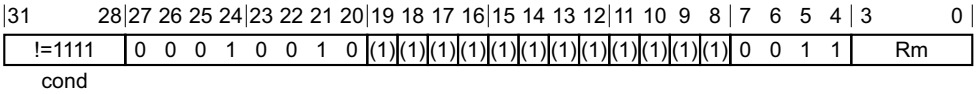
```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_A32 then
        LR = PC - 4;
    else
        LR = PC<31:1> : '1';
    if targetInstrSet == InstrSet_A32 then
        targetAddress = Align(PC,4) + imm32;
    else
        targetAddress = PC + imm32;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress, BranchType_DIRCALL);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.26 BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address specified in the register, and if necessary changes to the instruction set indicated by bit[0] of the register value. If the value in bit[0] is 0, the instruction set after the branch will be A32. If the value in bit[0] is 1, the instruction set after the branch will be T32.

A1



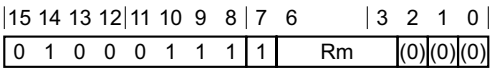
A1 variant

```
BLX{<c>}{<q>} <Rm>
```

Decode for this encoding

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
BLX{<c>}{<q>} <Rm>
```

Decode for this encoding

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    target = R[m];
    if CurrentInstrSet() == InstrSet_A32 then
        next_instr_addr = PC - 4;
        LR = next_instr_addr;
    else
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    next_instr_addr = PC - 2;
    LR = next_instr_addr<31:1> : '1';
BXWritePC(target, BranchType_INDCALL);
```

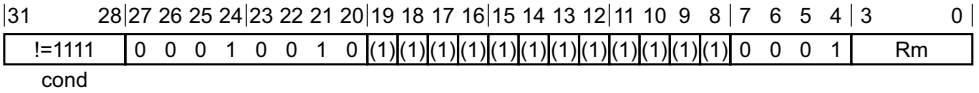
Non-Confidential

F5.1.27 BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

A1



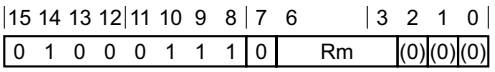
A1 variant

```
BX{<c>}{<q>} <Rm>
```

Decode for this encoding

```
m = UInt(Rm);
```

T1



T1 variant

```
BX{<c>}{<q>} <Rm>
```

Decode for this encoding

```
m = UInt(Rm);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rm> For encoding A1: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.

For encoding T1: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.

Note

If <Rm> is the PC at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the `BXWritePC()` pseudocode function has bits<1:0> = '10'.

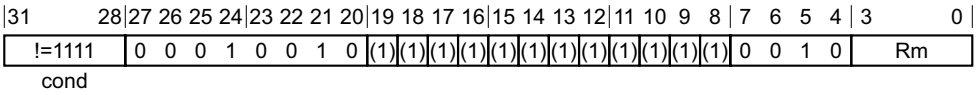
F5.1.28 BXJ

Branch and Exchange, previously Branch and Exchange Jazelle.

In Armv8, BXJ behaves as a BX instruction, see BX. This means it causes a branch to an address and instruction set specified by a register.

A1



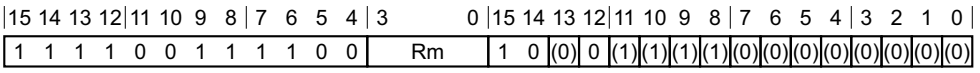
A1 variant

```
BXJ{<c>}{<q>} <Rm>
```

Decode for this encoding

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
BXJ{<c>}{<q>} <Rm>
```

Decode for this encoding

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

Operation for all encodings

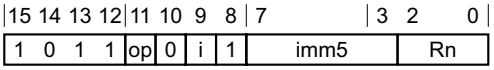
```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m], BranchType_INDIR);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.29 CBNZ, CBZ

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

T1



CBNZ variant

Applies when `op == 1`.

```
CBNZ{<q>} <Rn>, <label>
```

CBZ variant

Applies when `op == 0`.

```
CBZ{<q>} <Rn>, <label>
```

Decode for all variants of this encoding

```
n = UInt(Rn);  imm32 = ZeroExtend(i:imm5:'0', 32);  nonzero = (op == '1');
if InITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rn>`	Is the general-purpose register to be tested, encoded in the "Rn" field.
`<label>`	Is the program label to be conditionally branched to. Its offset from the PC, a multiple of 2 and in the range 0 to 126, is encoded as "i:imm5" times 2.

Operation

```
EncodingSpecificOperations();
if nonzero != IsZero(R[n]) then
    BranchWritePC(PC + imm32, BranchType_DIR);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

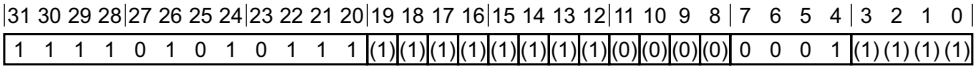
F5.1.30 CLREX

Clear-Exclusive clears the local monitor of the executing PE.

A1



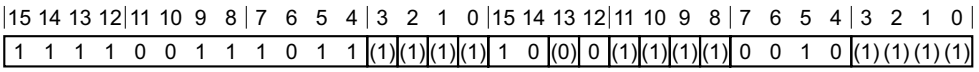
A1 variant

```
CLREX{<c>}{<q>}
```

Decode for this encoding

```
// No additional decoding required
```

T1



T1 variant

```
CLREX{<c>}{<q>}
```

Decode for this encoding

```
// No additional decoding required
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> For encoding A1: see *Standard assembler syntax fields* on page F2-3908. Must be AL or omitted.
For encoding T1: see *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

Operation for all encodings

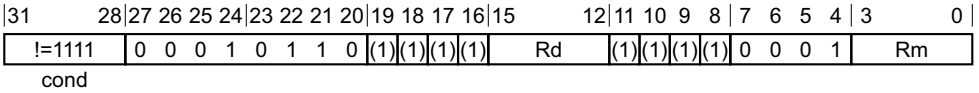
```
if ConditionPassed() then
    EncodingSpecificOperations();
    ClearExclusiveLocal(ProcessorID());
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.31 CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.

A1



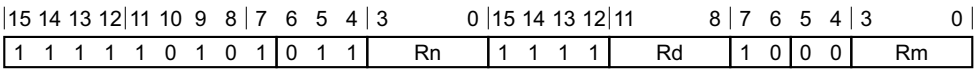
A1 variant

```
CLZ{<c>}{<q>} <Rd>, <Rm>
```

Decode for this encoding

```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
CLZ{<c>}{<q>} <Rd>, <Rm>
```

Decode for this encoding

```
d = UInt(Rd);  m = UInt(Rm);  n = UInt(Rn);
if m != n || d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `m != n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes with the additional decode: m = UInt(Rn);.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field.

For encoding T1: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

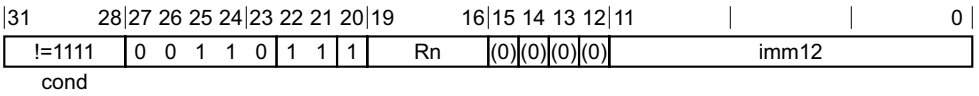
F5.1.32 CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

A1



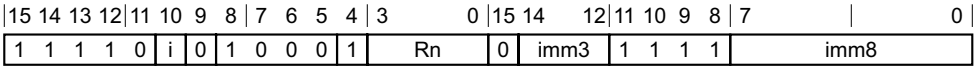
A1 variant

```
CMN{<c>}{<q>} <Rn>, #<const>
```

Decode for this encoding

```
n = UInt(Rn);  imm32 = A32ExpandImm(imm12);
```

T1



T1 variant

```
CMN{<c>}{<q>} <Rn>, #<const>
```

Decode for this encoding

```
n = UInt(Rn);  imm32 = T32ExpandImm(i:imm3:imm8);
if n == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

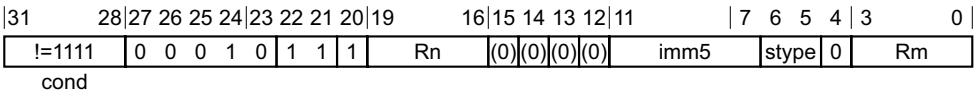
F5.1.33 CMN (register)

Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

A1



Rotate right with extend variant

Applies when `imm5 == 00000 && stype == 11`.

```
CMN{<c>}{<q>} <Rn>, <Rm>, RRX
```

Shift or rotate by value variant

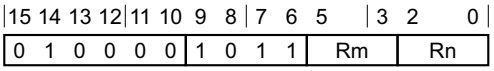
Applies when `!(imm5 == 00000 && stype == 11)`.

```
CMN{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

T1



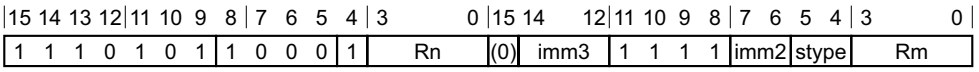
T1 variant

```
CMN{<c>}{<q>} <Rn>, <Rm>
```

Decode for this encoding

```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



Rotate right with extend variant

Applies when `imm3 == 000 && imm2 == 00 && stype == 11`.

```
CMN{<c>}{<q>} <Rn>, <Rm>, RRX
```

Shift or rotate by value variant

Applies when `!(imm3 == 000 && imm2 == 00 && stype == 11)`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
CMN{<c>}.W <Rn>, <Rm> // <Rn>, <Rm> can be represented in T1
CMN{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rn>` For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL`	when `stype = 00`
`LSR`	when `stype = 01`
`ASR`	when `stype = 10`
`ROR`	when `stype = 11`

`<amount>` For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

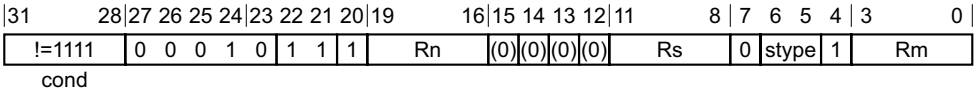
F5.1.34 CMN (register-shifted register)

Compare Negative (register-shifted register) adds a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1



A1 variant

```
CMN{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>
```

Decode for this encoding

```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(stype);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<type> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- LSL when stype = 00
- LSR when stype = 01
- ASR when stype = 10
- ROR when stype = 11

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    PSTATE.<N,Z,C,V> = nzcv;
```

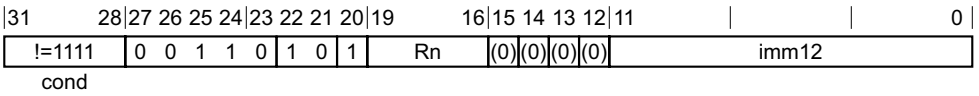
F5.1.35 CMP (immediate)

Compare (immediate) subtracts an immediate value from a register value. It updates the condition flags based on the result, and discards the result.

A1



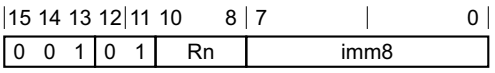
A1 variant

```
CMP{<c>}{<q>} <Rn>, #<const>
```

Decode for this encoding

```
n = UInt(Rn);  imm32 = A32ExpandImm(imm12);
```

T1



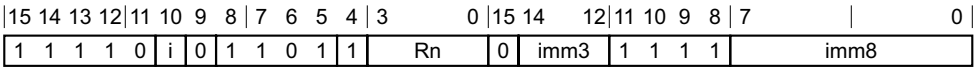
T1 variant

```
CMP{<c>}{<q>} <Rn>, #<imm8>
```

Decode for this encoding

```
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
```

T2



T2 variant

```
CMP{<c>}.W <Rn>, #<const> // <Rd>, <const> can be represented in T1
CMP{<c>}{<q>} <Rn>, #<const>
```

Decode for this encoding

```
n = UInt(Rn);  imm32 = T32ExpandImm(i:imm3:imm8);
if n == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

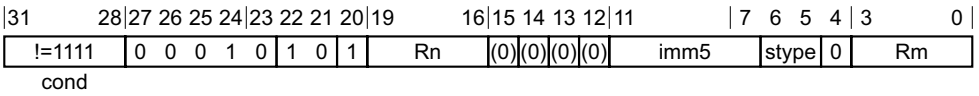
F5.1.36 CMP (register)

Compare (register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

A1



Rotate right with extend variant

Applies when `imm5 == 00000 && stype == 11`.

```
CMP{<c>}{<q>} <Rn>, <Rm>, RRX
```

Shift or rotate by value variant

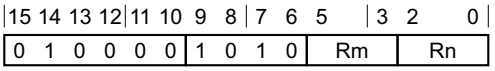
Applies when `!(imm5 == 00000 && stype == 11)`.

```
CMP{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

T1



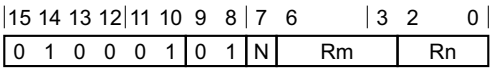
T1 variant

```
CMP{<c>}{<q>} <Rn>, <Rm> // <Rn> and <Rm> both from R0-R7
```

Decode for this encoding

```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



T2 variant

```
CMP{<c>}{<q>} <Rn>, <Rm> // <Rn> and <Rm> not both from R0-R7
```

Decode for this encoding

```
n = UInt(N:Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
if n < 8 && m < 8 then UNPREDICTABLE;
if n == 15 || m == 15 then UNPREDICTABLE;
```

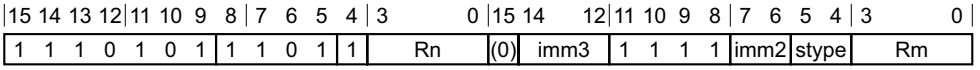
Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CONSTRAINED UNPREDICTABLE behavior

If `n < 8 && m < 8`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The condition flags become UNKNOWN.

T3



Rotate right with extend variant

Applies when `imm3 == 000 && imm2 == 00 && stype == 11`.

```
CMP{<c>}{<q>} <Rn>, <Rm>, RRX
```

Shift or rotate by value variant

Applies when `!(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
CMP{<c>}.W <Rn>, <Rm> // <Rn>, <Rm> can be represented in T1 or T2
CMP{<c>}{<q>} <Rn>, <Rm>, <shift> #<amount>
```

Decode for all variants of this encoding

```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rn>` For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1 and T3: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T2: is the first general-purpose source register, encoded in the "N:Rn" field.

`<Rm>` For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1, T2 and T3: is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL` when `stype = 00`

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`LSR` when `stype = 01`

`ASR` when `stype = 10`

`ROR` when `stype = 11`

`<amount>` For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

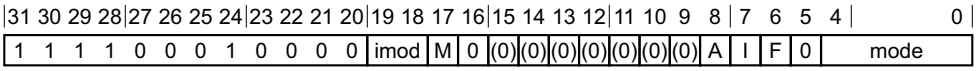
F5.1.38 CPS, CPSID, CPSIE

Change PE State changes one or more of the PSTATE.{A, I, F} interrupt mask bits and, optionally, the PSTATE.M mode field, without changing any other PSTATE bits.

CPS is treated as NOP if executed in User mode unless it is defined as being CONSTRAINED UNPREDICTABLE elsewhere in this section.

The PE checks whether the value being written to PSTATE.M is legal. See *Illegal changes to PSTATE.M* on page G1-5497.

A1



CPS variant

Applies when imod == 00 && M == 1.

```
CPS{<q>} #<mode> // Cannot be conditional
```

CPSID variant

Applies when imod == 11 && M == 0.

```
CPSID{<q>} <iflags> // Cannot be conditional
```

CPSID variant

Applies when imod == 11 && M == 1.

```
CPSID{<q>} <iflags> , #<mode> // Cannot be conditional
```

CPSIE variant

Applies when imod == 10 && M == 0.

```
CPSIE{<q>} <iflags> // Cannot be conditional
```

CPSIE variant

Applies when imod == 10 && M == 1.

```
CPSIE{<q>} <iflags> , #<mode> // Cannot be conditional
```

Decode for all variants of this encoding

```
if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10');  disable = (imod == '11');  changemode = (M == '1');
affectA = (A == '1');  affectI = (I == '1');  affectF = (F == '1');
if (imod == '00' && M == '0') || imod == '01' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If imod == '01', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If `imod == '00' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

If `mode != '00000' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: changemode = TRUE.
- The instruction executes as described, and the value specified by mode is ignored. There are no additional side-effects.

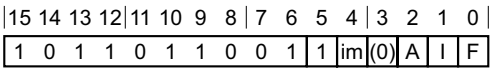
If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction behaves as if imod<1> == '0'.
- The instruction behaves as if A:I:F has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction behaves as if imod<1> == '1'.
- The instruction behaves as if A:I:F == '000'.

T1



CPSID variant

Applies when `im == 1`.

```
CPSID{<q>} <iflags> // Not permitted in IT block
```

CPSIE variant

Applies when `im == 0`.

```
CPSIE{<q>} <iflags> // Not permitted in IT block
```

Decode for all variants of this encoding

```
if A:I:F == '000' then UNPREDICTABLE;
enable = (im == '0');  disable = (im == '1');  changemode = FALSE;
affectA = (A == '1');  affectI = (I == '1');  affectF = (F == '1');
if InITBlock() then UNPREDICTABLE;
```

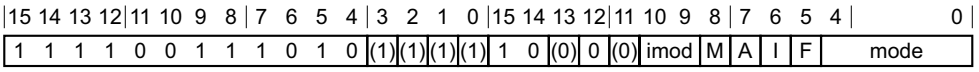
CONSTRAINED UNPREDICTABLE behavior

If A:I:F == '000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

T2



CPS variant

Applies when imod == 00 && M == 1.

```
CPS{<q>} #<mode> // Not permitted in IT block
```

CPSID variant

Applies when imod == 11 && M == 0.

```
CPSID.W <iflags> // Not permitted in IT block
```

CPSID variant

Applies when imod == 11 && M == 1.

```
CPSID{<q>} <iflags>, #<mode> // Not permitted in IT block
```

CPSIE variant

Applies when imod == 10 && M == 0.

```
CPSIE.W <iflags> // Not permitted in IT block
```

CPSIE variant

Applies when imod == 10 && M == 1.

```
CPSIE{<q>} <iflags>, #<mode> // Not permitted in IT block
```

Decode for all variants of this encoding

```
if imod == '00' && M == '0' then SEE "Hint instructions";
if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10');  disable = (imod == '11');  changemode = (M == '1');
affectA = (A == '1');  affectI = (I == '1');  affectF = (F == '1');
if imod == '01' || InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If imod == '01', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode != '00000' && M == '0', then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The instruction executes with the additional decode: changemode = TRUE.
- The instruction executes as described, and the value specified by mode is ignored. There are no additional side-effects.

If imod<1> == '1' && A:I:F == '000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if imod<1> == '0'.
- The instruction behaves as if A:I:F has an UNKNOWN nonzero value.

If imod<1> == '0' && A:I:F != '000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if imod<1> == '1'.
- The instruction behaves as if A:I:F == '000'.

Notes for all encodings

Hint instructions: In encoding T2, if the imod field is 00 and the M bit is 0, a hint instruction is encoded. To determine which hint instruction, see *Branches and miscellaneous control* on page F3-3979.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<q> See *Standard assembler syntax fields* on page F2-3908.

<iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

- a — Sets the A bit in the instruction, causing the specified effect on PSTATE.A, the SError interrupt mask bit.
- i — Sets the I bit in the instruction, causing the specified effect on PSTATE.I, the IRQ interrupt mask bit.
- f — Sets the F bit in the instruction, causing the specified effect on PSTATE.F, the FIQ interrupt mask bit.

<mode> Is the number of the mode to change to, in the range 0 to 31, encoded in the "mode" field.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
    EncodingSpecificOperations();
    if PSTATE.EL != EL0 then
        if enable then
            if affectA then PSTATE.A = '0';
            if affectI then PSTATE.I = '0';
            if affectF then PSTATE.F = '0';
        if disable then
            if affectA then PSTATE.A = '1';
            if affectI then PSTATE.I = '1';
            if affectF then PSTATE.F = '1';
        if changemode then
            // AArch32.WriteModeByInstr() sets PSTATE.IL to 1 if this is an illegal mode change.
```

F5.1.39 CRC32

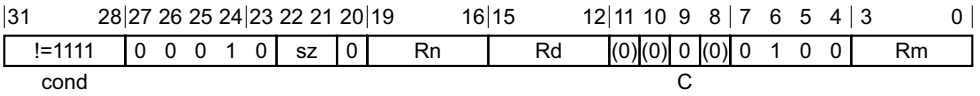
CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

Note

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

A1



CRC32B variant

Applies when sz == 00.

```
CRC32B{<q>} <Rd>, <Rn>, <Rm>
```

CRC32H variant

Applies when sz == 01.

```
CRC32H{<q>} <Rd>, <Rn>, <Rm>
```

CRC32W variant

Applies when sz == 10.

```
CRC32W{<q>} <Rd>, <Rn>, <Rm>
```

Decode for all variants of this encoding

```
if ! HaveCRCExt() then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if cond != '1110' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If size == 64, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: size = 32;.

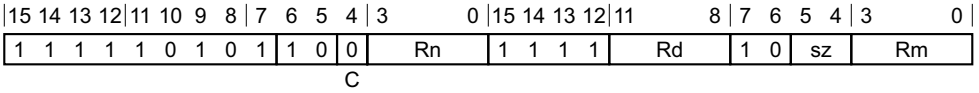
If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction executes unconditionally.
- The instruction executes conditionally.

T1



CRC32B variant

Applies when `sz == 00`.

```
CRC32B{<q>} <Rd>, <Rn>, <Rm>
```

CRC32H variant

Applies when `sz == 01`.

```
CRC32H{<q>} <Rd>, <Rn>, <Rm>
```

CRC32W variant

Applies when `sz == 10`.

```
CRC32W{<q>} <Rd>, <Rn>, <Rm>
```

Decode for all variants of this encoding

```
if InITBlock() then UNPREDICTABLE;
if ! HaveCRCExt() then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: size = 32;.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<q>`	See *Standard assembler syntax fields* on page F2-3908. An `CRC32` instruction must be unconditional.
`<Rd>`	Is the general-purpose accumulator output register, encoded in the "Rd" field.
`<Rn>`	Is the general-purpose accumulator input register, encoded in the "Rn" field.
`<Rm>`	Is the general-purpose data source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();

    acc = R[n];             // accumulator
    val = R[m]<size-1:0>;   // input value
    poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;
    tempacc = BitReverse(acc):Zeros(size);
    tempval = BitReverse(val):Zeros(32);
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

F5.1.40 CRC32C

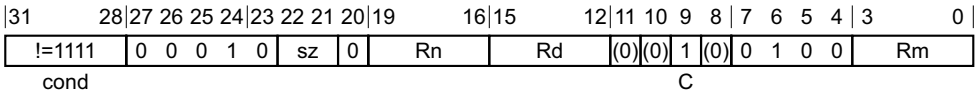
CRC32C performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

Note

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

A1



CRC32CB variant

Applies when sz == 00.

```
CRC32CB{<q>} <Rd>, <Rn>, <Rm>
```

CRC32CH variant

Applies when sz == 01.

```
CRC32CH{<q>} <Rd>, <Rn>, <Rm>
```

CRC32CW variant

Applies when sz == 10.

```
CRC32CW{<q>} <Rd>, <Rn>, <Rm>
```

Decode for all variants of this encoding

```
if ! HaveCRCExt() then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if cond != '1110' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If size == 64, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: size = 32;.

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.41 CSDB

Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions and instructions that write to the PC appearing in program order after the CSDB can be speculatively executed using the results of any:

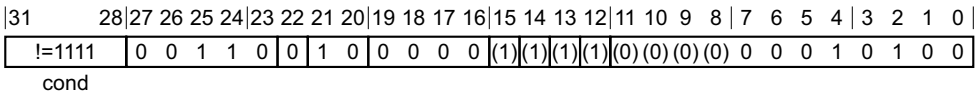
- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions and conditional instructions that write to the PC appearing in program order before the CSDB that have not been architecturally resolved.

Note

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

A1



A1 variant

```
CSDB{<c>}{<q>}
```

Decode for this encoding

```
if cond != '1110' then UNPREDICTABLE;      // CSDB must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

F5.1.43 DCPS1

Debug Change PE State to EL1 allows the debugger to move the PE into EL1 from EL0 or to a specific mode at the current Exception Level.

DCPS1 is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL2 is implemented, EL2 is implemented and enabled in the current Security state, and any of:
  - EL2 is using AArch32 and HCR.TGE is set to 1.
  - EL2 is using AArch64 and HCR_EL2.TGE is set to 1.

When the PE executes DCPS1 at EL0, EL1 or EL3:

- If EL3 or EL1 is using AArch32, the PE enters SVC mode and LR_svc, SPSR_svc, DLR, and DSPSR become UNKNOWN. If DCPS1 is executed in Monitor mode, SCR.NS is cleared to 0.
- If EL1 is using AArch64, the PE enters EL1 using AArch64, selects SP_EL1, and ELR_EL1, ESR_EL1, SPSR_EL1, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

When the PE executes DCPS1 at EL2 the PE does not change mode, and ELR_hyp, HSR, SPSR_hyp, DLR and DSPSR become UNKNOWN.

For more information on the operation of this instruction, see *DCPS<n>* on page H2-6731.

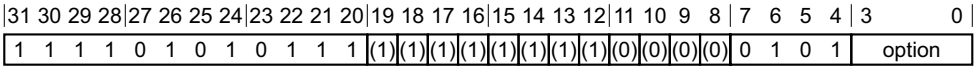
F5.1.46 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see *Data Memory Barrier (DMB)* on page E2-3824.

A1



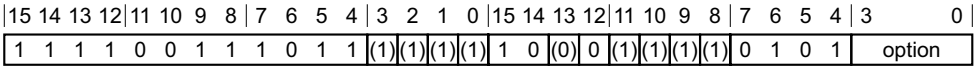
A1 variant

```
DMB{<c>}{<q>} {<option>}
```

Decode for this encoding

```
// No additional decoding required
```

T1



T1 variant

```
DMB{<c>}{<q>} {<option>}
```

Decode for this encoding

```
// No additional decoding required
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` For encoding A1: see *Standard assembler syntax fields* on page F2-3908. Must be `AL` or omitted.
For encoding T1: see *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<option>` Specifies an optional limitation on the barrier operation. Values are:

- `SY` Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = `0b1111`.
- `ST` Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. `SYST` is a synonym for `ST`. Encoded as option = `0b1110`.
- `LD` Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b1101`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = `0b1011`.

`ISHST` Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = `0b1010`.

`ISHLD` Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b1001`.

`NSH` Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = `0b0111`.

`NSHST` Non-shareable is the required shareability domain, writes are the required access type both before and after the barrier instruction. Encoded as option = `0b0110`.

`NSHLD` Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b0101`.

`OSH` Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = `0b0011`.

`OSHST` Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = `0b0010`.

`OSHLD` Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b0001`.

For more information on whether an access is before or after a barrier instruction, see *Data Memory Barrier (DMB)* on page E2-3824. All other encodings of option are reserved. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

Note

The instruction supports the following alternative `<option>` values, but Arm recommends that software does not use these alternative values:

- `SH` as an alias for `ISH`.
- `SHST` as an alias for `ISHST`.
- `UN` as an alias for `NSH`.
- `UNST` as an alias for `NSHST`.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0001'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Reads;
        when '0010'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Writes;
        when '0011'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_All;
        when '0101'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Reads;
        when '0110'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Writes;
        when '0111'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_All;
        when '1001'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Reads;
        when '1010'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Writes;
        when '1011'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_All;
        when '1101'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Reads;
        when '1110'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Writes;
        otherwise    domain = MBReqDomain_FullSystem;      types = MBReqTypes_All;

    if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
        if HCR.BSU == '11' then
            domain = MBReqDomain_FullSystem;
        if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then

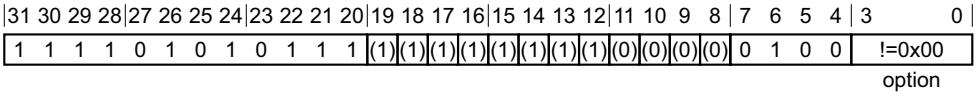
F5.1.47 DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier (DSB)* on page E2-3824.

A1



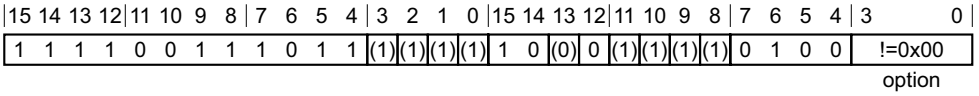
A1 variant

```
DSB{<c>}{<q>} {<option>}
```

Decode for this encoding

```
// No additional decoding required
```

T1



T1 variant

```
DSB{<c>}{<q>} {<option>}
```

Decode for this encoding

```
// No additional decoding required
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` For encoding A1: see *Standard assembler syntax fields* on page F2-3908. Must be `AL` or omitted.
For encoding T1: see *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<option>` Specifies an optional limitation on the barrier operation. Values are:

- `SY` Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = `0b1111`.
- `ST` Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. `SYST` is a synonym for `ST`. Encoded as option = `0b1110`.
- `LD` Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b1101`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = `0b1011`.

`ISHST` Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = `0b1010`.

`ISHLD` Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b1001`.

`NSH` Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = `0b0111`.

`NSHST` Non-shareable is the required shareability domain, writes are the required access type both before and after the barrier instruction. Encoded as option = `0b0110`.

`NSHLD` Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b0101`.

`OSH` Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = `0b0011`.

`OSHST` Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = `0b0010`.

`OSHLD` Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = `0b0001`.

For more information on whether an access is before or after a barrier instruction, see *Data Synchronization Barrier (DSB)* on page E2-3824. All other encodings of option are reserved. All unsupported and reserved options must execute as a full system DSB operation, but software must not rely on this behavior.

Note

The instruction supports the following alternative `<option>` values, but Arm recommends that software does not use these alternative values:

- `SH` as an alias for `ISH`.
- `SHST` as an alias for `ISHST`.
- `UN` as an alias for `NSH`.
- `UNST` as an alias for `NSHST`.

F5.1.48 EOR, EORS (immediate)

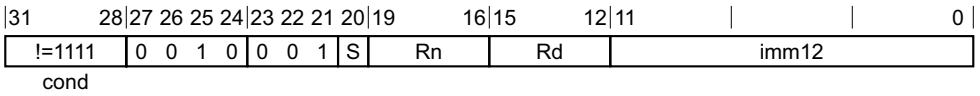
Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



EOR variant

Applies when S == 0.

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

EORS variant

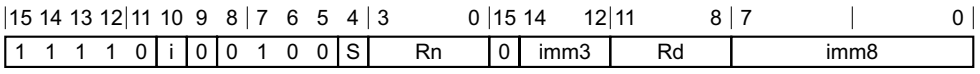
Applies when S == 1.

```
EORS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1



EOR variant

Applies when S == 0.

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

EORS variant

Applies when S == 1 && Rd != 1111.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
EORS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "TEQ (immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the EORS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

F5.1.49 EOR, EORS (register)

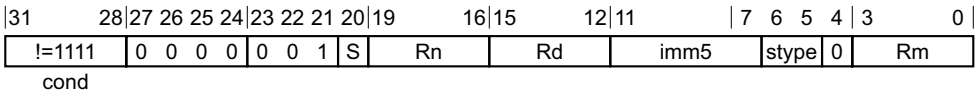
Bitwise Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



EOR, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

EOR, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

EORS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
EORS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

EORS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

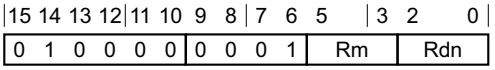
```
EORS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1



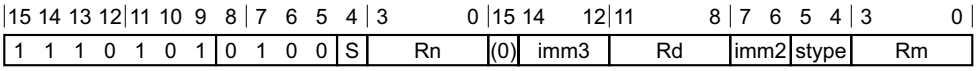
T1 variant

```
EOR<c>{<q>} {<Rdn>,} <Rdn>, <Rm> // Inside IT block
EORS{<q>} {<Rdn>,} <Rdn>, <Rm> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



EOR, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

EOR, shift or rotate by value variant

Applies when `S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
EOR<c>.W {<Rd>,} <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
EOR{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

EORS, rotate right with extend variant

Applies when `S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11`.

```
EORS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

EORS, shift or rotate by value variant

Applies when `S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11) && Rd != 1111`.

```
EORS.W {<Rd>,} <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
EORS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE "TEQ (register)";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Non-Confidential

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rdn>` Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the EORS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as `<Rn>`.

`<Rn>` For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

`LSL`	when `stype = 00`
`LSR`	when `stype = 01`
`ASR`	when `stype = 10`
`ROR`	when `stype = 11`

`<amount>` For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if `EORS <Rd>, <Rn>, <Rd>` has `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `EORS <Rd>, <Rn>` had been written
- Inside an IT block, if `EOR<c> <Rd>, <Rn>, <Rd>` has `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `EOR<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the `.W` qualifier.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
else
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

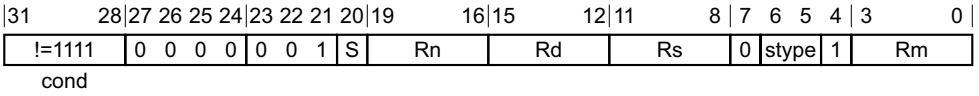
F5.1.50 EOR, EORS (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1



Flag setting variant

Applies when `S == 1`.

```
EORS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when `S == 0`.

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.

`<Rn>` Is the first general-purpose source register, encoded in the "Rn" field.

`<Rm>` Is the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

- `LSL` when `stype = 00`
- `LSR` when `stype = 01`
- `ASR` when `stype = 10`
- `ROR` when `stype = 11`

`<Rs>` Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Non-Confidential

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Non-Confidential

F5.1.51 ERET

Exception Return.

The PE branches to the address held in the register holding the preferred return address, and restores PSTATE from SPSR_<current_mode>.

The register holding the preferred return address is:

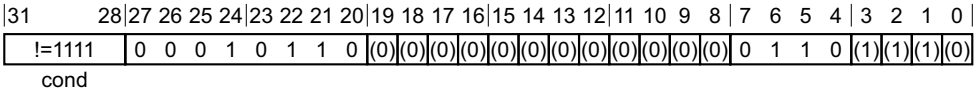
- ELR_hyp, when executing in Hyp mode.
- LR, when executing in a mode other than Hyp mode, User mode, or System mode.

The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.

Exception Return is CONSTRAINED UNPREDICTABLE in User mode and System mode.

In Debug state, the T1 encoding of ERET executes the DRPS operation.

A1



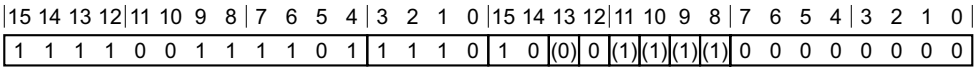
A1 variant

```
ERET{<c>}{<q>}
```

Decode for this encoding

```
// No additional decoding required
```

T1



T1 variant

```
ERET{<c>}{<q>}
```

Decode for this encoding

```
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Halted() then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;                          // UNDEFINED or NOP
        else
            new_pc_value = if PSTATE.EL == EL2 then ELR_hyp else R[14];
            AArch32.ExceptionReturn(new_pc_value, SPSR[]);
    else                                            // Perform DRPS operation in Debug state
        if PSTATE.M == M32_User then
            UNDEFINED;
        elsif PSTATE.M == M32_System then
            UNPREDICTABLE;                          // UNDEFINED or NOP
        else
            SynchronizeContext();
            SetPSTATEFromPSR(SPSR[]);
            // PSTATE.{N,Z,C,V,Q,GE,SS,A,I,F} are not observable and ignored in Debug state, so
            // behave as if UNKNOWN.
            PSTATE.<N,Z,C,V,Q,GE,SS,A,I,F> = bits(13) UNKNOWN;
            // In AArch32 Debug state, all instructions are T32 and unconditional.
            PSTATE.IT = '00000000';  PSTATE.T = '1';        // PSTATE.J is RES0
            DLR = bits(32) UNKNOWN;  DSPSR = bits(32) UNKNOWN;
            UpdateEDSCRFields();                    // Update EDSCR PE state flags
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.52 ESB

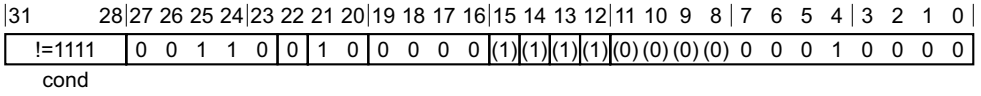
Error Synchronization Barrier is an error synchronization event that might also update DISR and VDISR. This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the ARM(R) Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for ARMv8-A architecture profile.

If the RAS Extension is not implemented, this instruction executes as a `NOP`.

A1

ARMv8.2



A1 variant

```
ESB{<c>}{<q>}
```

Decode for this encoding

```
if !HaveRASExt() then EndOfInstruction();  // Instruction executes as NOP
if cond != '1110' then UNPREDICTABLE;      // ESB must be encoded with AL condition
```

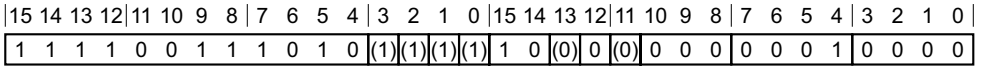
CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

ARMv8.2



T1 variant

```
ESB{<c>}.W
```

Decode for this encoding

```
if !HaveRASExt() then EndOfInstruction();  // Instruction executes as NOP
if InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();

    SynchronizeErrors();
    AArch32.ESBOperation();
    if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then AArch32.vESBOperation();
    TakeUnmaskedSErrorInterrupts();
```

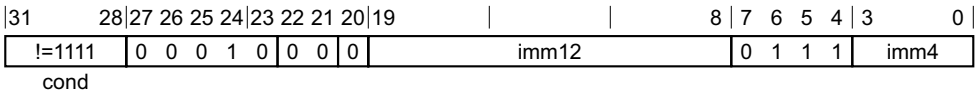
F5.1.53 HLT

Halting breakpoint causes a software breakpoint to occur.

Halting breakpoint is always unconditional, even inside an IT block.

A1



A1 variant

```
HLT{<q>} {#}<imm>
```

Decode for this encoding

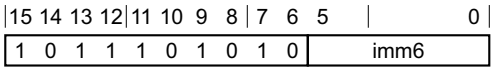
```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
if cond != '1110' then UNPREDICTABLE; // HLT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1



T1 variant

```
HLT{<q>} {#}<imm>
```

Decode for this encoding

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<q>` See *Standard assembler syntax fields* on page F2-3908. An `HLT` instruction must be unconditional.

`<imm>` For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For encoding T1: is a 6-bit unsigned immediate, in the range 0 to 63, encoded in the "imm6" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Operation for all encodings

```
EncodingSpecificOperations();
Halt(DebugHalt_HaltInstruction);
```

Non-Confidential

F5.1.54 HVC

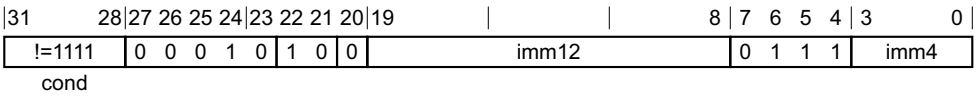
Hypervisor Call causes a Hypervisor Call exception. For more information see *Hypervisor Call (HVC) exception* on page G1-5542. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is:

- UNDEFINED in Secure state, and in User mode in Non-secure state.
- When SCR.HCE is set to 0, UNDEFINED in Non-secure EL1 modes and CONSTRAINED UNPREDICTABLE in Hyp mode.

On executing an HVC instruction, the HSR reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see *Use of the HSR* on page G5-5836.

A1



A1 variant

```
HVC{<q>} {#}<imm16>
```

Decode for this encoding

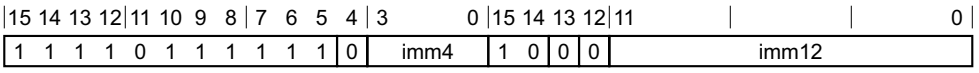
```
if cond != '1110' then UNPREDICTABLE;
imm16 = imm12:imm4;
```

CONSTRAINED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1



T1 variant

```
HVC{<q>} {#}<imm16>
```

Decode for this encoding

```
imm16 = imm4:imm12;
if InITBlock() then UNPREDICTABLE;
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<q> See *Standard assembler syntax fields* on page F2-3908. An HVC instruction must be unconditional.

<imm16> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

Operation for all encodings

```
EncodingSpecificOperations();
if !HaveEL(EL2) || PSTATE.EL == EL0 || (IsSecure() && !IsSecureEL2Enabled()) then
    UNDEFINED;

if HaveEL(EL3) then
    if ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2 then
        UNPREDICTABLE;
    else
        hvc_enable = SCR_GEN[].HCE;
else
    hvc_enable = if ELUsingAArch32(EL2) then NOT(HCR.HCD) else NOT(HCR_EL2.HCD);

if hvc_enable == '0' then
    UNDEFINED;
else
    AArch32.CallHypervisor(imm16);
```

CONSTRAINED UNPREDICTABLE behavior

If ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

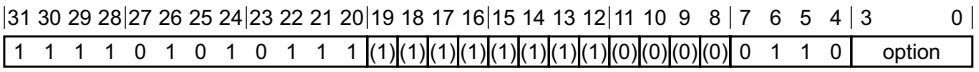
F5.1.55 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see *Instruction Synchronization Barrier (ISB)* on page E2-3824.

A1



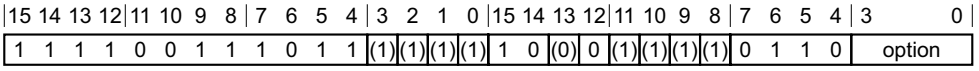
A1 variant

```
ISB{<c>}{<q>} {<option>}
```

Decode for this encoding

```
// No additional decoding required
```

T1



T1 variant

```
ISB{<c>}{<q>} {<option>}
```

Decode for this encoding

```
// No additional decoding required
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` For encoding A1: see *Standard assembler syntax fields* on page F2-3908. Must be `AL` or omitted.
For encoding T1: see *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<option>` Specifies an optional limitation on the barrier operation. Values are:

`SY` Full system barrier operation, encoded as option = `0b1111`. Can be omitted.

All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.56 IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

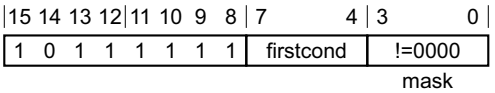
16-bit instructions in the IT block, other than CMP, CMN and TST, do not set the condition flags. An IT instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the CPSR restores ITSTATE to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

Many uses of the IT instruction are deprecated for performance reasons, and an implementation might include ITD controls that can disable those uses of IT, making them UNDEFINED.

For more information see *Conditional execution* on page F2-3909 and *Conditional instructions* on page F1-3867. The first of these sections includes more information about the ITD controls.

T1



T1 variant

```
IT{<x>{<y>{<z>}}}{<q>} <cond>
```

Decode for this encoding

```
if mask == '0000' then SEE "Related encodings";
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The '1111' condition is treated as being the same as the '1110' condition, meaning always, and the ITSTATE state machine is progressed in the same way as for any other cond_base value.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Miscellaneous 16-bit instructions* on page F3-3943.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Assembler symbols

<x> The condition for the second instruction in the IT block. If omitted, the "mask" field is set to 0b1000. If present it is encoded in the "mask[3]" field:

T firstcond[0]

E NOT firstcond[0]

<y> The condition for the third instruction in the IT block. If omitted and <x> is present, the "mask[2:0]" field is set to 0b100. If <y> is present it is encoded in the "mask[2]" field:

T firstcond[0]

E NOT firstcond[0]

<z> The condition for the fourth instruction in the IT block. If omitted and <y> is present, the "mask[1:0]" field is set to 0b10. If <z> is present, the "mask[0]" field is set to 1, and it is encoded in the "mask[1]" field:

T firstcond[0]

E NOT firstcond[0]

<q> See *Standard assembler syntax fields* on page F2-3908.

<cond> The condition for the first instruction in the IT block, encoded in the "firstcond" field. See Table F2-1 on page F2-3909 for the range of conditions available, and the encodings.

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See *Conditional instructions* on page F1-3867.

Operation

```
EncodingSpecificOperations();
AArch32.CheckITEnabled(mask);
PSTATE.IT<7:0> = firstcond:mask;
ShouldAdvanceIT = FALSE;
```

F5.1.61 LDAEXD

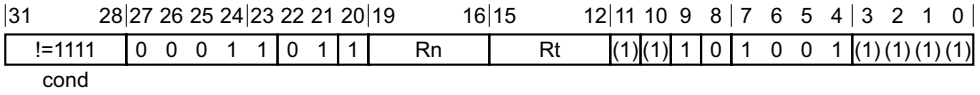
Load-Acquire Exclusive Doubleword loads a doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also acts as a barrier instruction with the ordering requirements described in *Load-Acquire, Store-Release* on page E2-3828.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-3853. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



A1 variant

```
LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

Decode for this encoding

```
t = UInt(Rt);  t2 = t + 1;  n = UInt(Rn);
if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

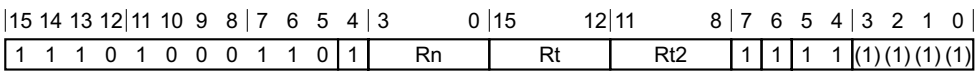
If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction is handled as described in *Using R15* on page K1-7607.

T1



T1 variant

```
LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The load instruction executes but the destination register takes an UNKNOWN value.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rt>`	For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. `<Rt>` must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Rt2>`	For encoding A1: is the second general-purpose register to be transferred. `<Rt2>` must be `<R(t+1)>`. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Rn>`	Is the general-purpose base register, encoded in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address, 8);
    value = MemO[address, 8];
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R[t]  = if BigEndian() then value<63:32> else value<31:0>;
    R[t2] = if BigEndian() then value<31:0>  else value<63:32>;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

F5.1.62 LDAEXH

Load-Acquire Exclusive Halfword loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-3828.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-3853. For information about memory accesses see *Memory accesses* on page F2-3913.

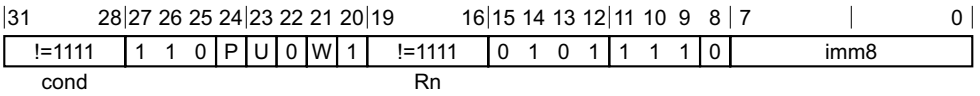
F5.1.64 LDC (immediate)

Load data to System register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to the DBGDTRTXint System register. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

In an implementation that includes EL2, the permitted LDC access to DBGDTRTXint can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general Non-secure System register accesses to debug registers* on page G1-5601.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

A1



Offset variant

Applies when P == 1 && W == 0.

```
LDC{<c>}{<q>} p14, c5, [<Rn>{, #{+/-}<imm>}]
```

Post-indexed variant

Applies when P == 0 && W == 1.

```
LDC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when P == 1 && W == 1.

```
LDC{<c>}{<q>} p14, c5, [<Rn>, #{+/-}<imm>]!
```

Unindexed variant

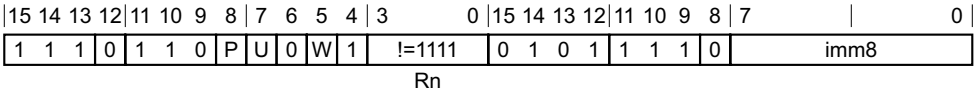
Applies when P == 0 && U == 1 && W == 0.

```
LDC{<c>}{<q>} p14, c5, [<Rn>], <option>
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE "LDC (literal)";
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn);  cp = 14;
imm32 = ZeroExtend(imm8:'00', 32);  index = (P == '1');  add = (U == '1');  wback = (W == '1');
```

T1



Offset variant

Applies when P == 1 && W == 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
LDC{<c>}{<q>} p14, c5, [<Rn>{, #{+/-}<imm>}]
```

Post-indexed variant

Applies when P == 0 && W == 1.

```
LDC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when P == 1 && W == 1.

```
LDC{<c>}{<q>} p14, c5, [<Rn>, #{+/-}<imm>]!
```

Unindexed variant

Applies when P == 0 && U == 1 && W == 0.

```
LDC{<c>}{<q>} p14, c5, [<Rn>], <option>
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE "LDC (literal)";
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn);  cp = 14;
imm32 = ZeroExtend(imm8:'00', 32);  index = (P == '1');  add = (U == '1');  wback = (W == '1');
```

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rn> Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see LDC (literal).

<option> Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
- \+ when U = 1

<imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

    // System register write to DBGDTRTXint.
    DBGDTR_EL0[] = MemA[address,4];

    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

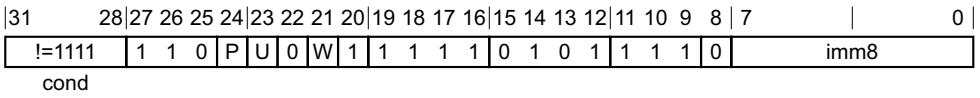
F5.1.65 LDC (literal)

Load data to System register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to the DBGDTRTXint System register. For information about memory accesses see *Memory accesses* on page F2-3913.

In an implementation that includes EL2, the permitted LDC access to DBGDTRTXint can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general Non-secure System register accesses to debug registers* on page G1-5601.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

A1



A1 variant

Applies when `!(P == 0 && U == 0 && W == 0)`.

```
LDC{<c>}{<q>} p14, c5, <label>
LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]
LDC{<c>}{<q>} p14, c5, [PC], <option>
```

Decode for this encoding

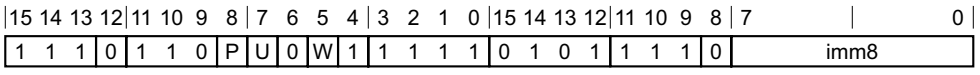
```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
index = (P == '1');  add = (U == '1');  cp = 14;  imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1



T1 variant

Applies when `!(P == 0 && U == 0 && W == 0)`.

```
LDC{<c>}{<q>} p14, c5, <label>
LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
index = (P == '1');  add = (U == '1');  cp = 14;  imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `W == '1' || P == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction executes as `LDC` (immediate) with writeback to the PC. The instruction is handled as described in *Using R15* on page K1-7607.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<option>` Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE` (encoded as U == 1).

If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE (encoded as U == 0)`.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    address = if index then offset_addr else Align(PC,4);

    // System register write to DBGDTRTXint.
    DBGDTR_EL0[] = MemA[address,4];
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Non-Confidential

F5.1.66 LDM, LDMIA, LDMFD

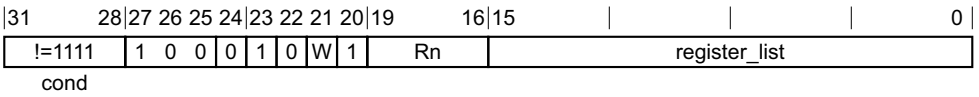
Load Multiple (Increment After, Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-3914.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see ARMv8.2-LSMAOC. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787. Related system instructions are LDM (User registers) and LDM (exception return).

This instruction is used by the alias POP (multiple registers). See *Alias conditions* on page F5-4226 for details of when each alias is preferred.

A1



A1 variant

```
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack
```

Decode for this encoding

```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

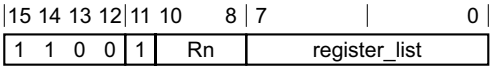
- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1



T1 variant

```
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack
```

Decode for this encoding

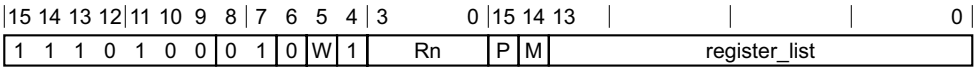
```
n = UInt(Rn);  registers = '00000000':register_list;  wback = (registers<n> == '0');
if BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T2



T2 variant

```
LDM{IA}{<c>}.W <Rn>{!}, <registers> // Preferred syntax, if <Rn>, '!' and <registers> can be represented
in T1
LDMFD{<c>}.W <Rn>{!}, <registers> // Alternate syntax, Full Descending stack, if <Rn>, '!' and
<registers> can be represented in T1
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack
```

Decode for this encoding

```
n = UInt(Rn);  registers = P:M:register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Alias conditions

Alias	of variant	is preferred when
POP (multiple registers)	T2	`W == '1' && Rn == '1101' && BitCount(P:M:register_list) > 1`
POP (multiple registers)	A1	`W == '1' && Rn == '1101' && BitCount(register_list) > 1`

Assembler symbols

`IA`	Is an optional suffix for the Increment After form.
`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rn>`	Is the general-purpose base register, encoded in the "Rn" field.
`!`	For encoding A1 and T2: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For encoding T1: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.

<registers> For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field.

For encoding T2: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.67 LDM (exception return)

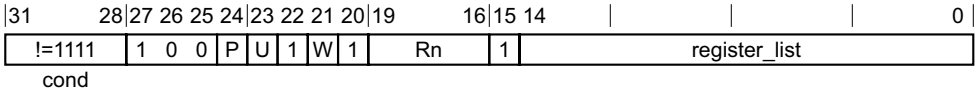
Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The SPSR of the current mode is copied to the CPSR. An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

Load Multiple (exception return) is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in debug state, and in User mode and System mode.

A1



A1 variant

```
LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers_with_pc>^
```

Decode for this encoding

```
n = UInt(Rn);  registers = register_list;
wback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<amode>` is one of:

`DA`	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
`FA`	Full Ascending. For this instruction, a synonym for `DA`.
`DB`	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
`EA`	Empty Ascending. For this instruction, a synonym for `DB`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IA — Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.

FD — Full Descending. For this instruction, a synonym for IA.

IB — Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.

ED — Empty Descending. For this instruction, a synonym for IB.

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers_with_pc> Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also *Encoding of lists of general-purpose registers and the PC* on page F2-3914.

Instructions with similar syntax but without the PC included in the registers list are described in LDM (User registers).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;                        // UNDEFINED or NOP
    else
        length = 4*BitCount(registers) + 4;
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;

        for i = 0 to 14
            if registers<i> == '1' then
                R[i] = MemA[address,4];  address = address + 4;
        new_pc_value = MemA[address,4];

        if wback && registers<n> == '0' then R[n] = if increment then R[n]+length else R[n]-length;
        if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;

        AArch32.ExceptionReturn(new_pc_value, SPSR[]);
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Non-Confidential

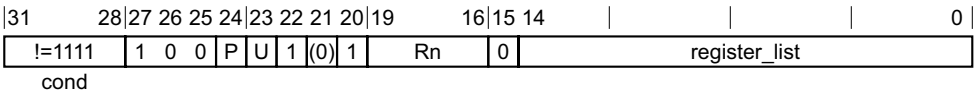
F5.1.68 LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Load Multiple (User registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see ARMv8.2-LSMAOC.

A1



A1 variant

```
LDM{<amode>}{<c>}{<q>} <Rn>, <registers_without_pc>^
```

Decode for this encoding

```
n = UInt(Rn);  registers = register_list;  increment = (U == '1');  wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<amode>` is one of:

`DA`	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
`FA`	Full Ascending. For this instruction, a synonym for `DA`.
`DB`	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
`EA`	Empty Ascending. For this instruction, a synonym for `DB`.
`IA`	Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
`FD`	Full Descending. For this instruction, a synonym for `IA`.
`IB`	Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ED Empty Descending. For this instruction, a synonym for IB.

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<registers_without_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the LDM instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also *Encoding of lists of general-purpose registers and the PC* on page F2-3914.

Instructions with similar syntax but with the PC included in <registers_without_pc> are described in LDM (exception return).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then  // Load User mode register
                Rmode[i, M32_User] = MemA[address,4];  address = address + 4;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

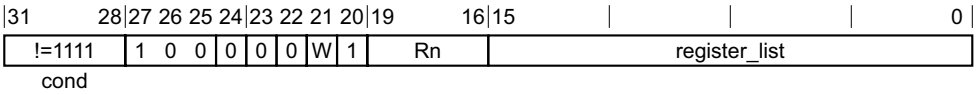
F5.1.69 LDMDA, LDMFA

Load Multiple Decrement After (Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-3914.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see ARMv8.2-LSMAOC. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787. Related system instructions are LDM (User registers) and LDM (exception return).

A1



A1 variant

```
LDMDA{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMFA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Ascending stack
```

Decode for this encoding

```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

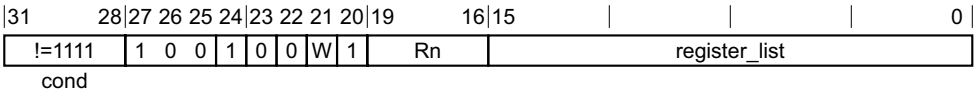
F5.1.70 LDMDB, LDMEA

Load Multiple Decrement Before (Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-3914.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see ARMv8.2-LSMAOC. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787. Related system instructions are LDM (User registers) and LDM (exception return).

A1



A1 variant

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMEA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Ascending stack
```

Decode for this encoding

```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T1 variant

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMEA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Ascending stack
```

Decode for this encoding

```
n = UInt(Rn);  registers = P:M:register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Non-Confidential

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rn>` Is the general-purpose base register, encoded in the "Rn" field.

`!` The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

`<registers>` For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

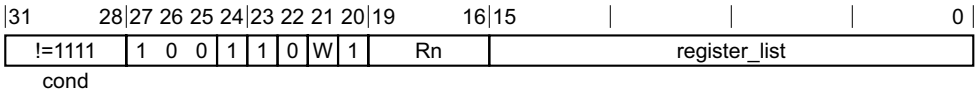
F5.1.71 LDMIB, LDMED

Load Multiple Increment Before (Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-3914.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see ARMv8.2-LSMAOC. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787. Related system instructions are LDM (User registers) and LDM (exception return).

A1



A1 variant

```
LDMIB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMED{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Descending stack
```

Decode for this encoding

```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

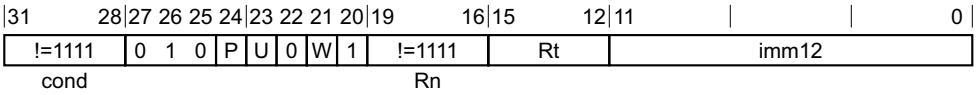
F5.1.72 LDR (immediate)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

This instruction is used by the alias POP (single register). See *Alias conditions* on page F5-4241 for details of when each alias is preferred.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDR{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDR{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDR{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE "LDR (literal)";
if P == '0' && W == '1' then SEE "LDRT";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if wback && n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

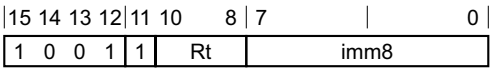
T1 variant

```
LDR{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

T2



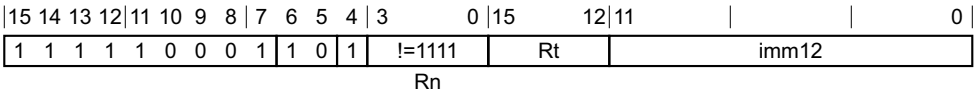
T2 variant

```
LDR{<c>}{<q>} <Rt>, [SP{, #{+}<imm>}]
```

Decode for this encoding

```
t = UInt(Rt);  n = 13;  imm32 = ZeroExtend(imm8:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

T3



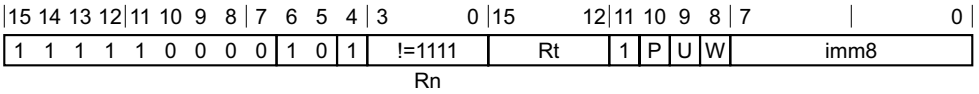
T3 variant

```
LDR{<c>}.W <Rt>, [<Rn> {, #{+}<imm>}] // <Rt>, <Rn>, <imm> can be represented in T1 or T2
LDR{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDR (literal)";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32); index = TRUE;  add = TRUE;
wback = FALSE; if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

T4



Offset variant

Applies when `P == 1 && U == 0 && W == 0`.

```
LDR{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 1`.

```
LDR{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDR{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE "LDR (literal)";
if P == '1' && U == '1' && W == '0' then SEE "LDRT";
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);
imm32 = ZeroExtend(imm8, 32); index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (wback && n == t) || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Alias conditions

Alias	of variant	is preferred when
POP (single register)	A1 (post-indexed)	`P == '0' && U == '1' && W == '0' && Rn == '1101' && imm12 == '000000000100'`
POP (single register)	T4 (post-indexed)	`Rn == '1101' && U == '1' && imm8 == '00000100'`

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

For encoding T1 and T2: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

`<Rn>` For encoding A1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDR (literal).

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when `U = 0`
- + when `U = 1`

+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.

For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.

For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

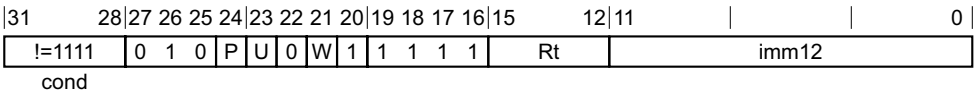
F5.1.73 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



A1 variant

Applies when `!(P == 0 && W == 1)`.

```
LDR{<c>}{<q>} <Rt>, <label> // Normal form
LDR{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative form
```

Decode for this encoding

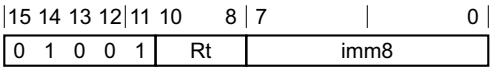
```
if P == '0' && W == '1' then SEE "LDRT";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDR (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15* on page K1-7607.

T1



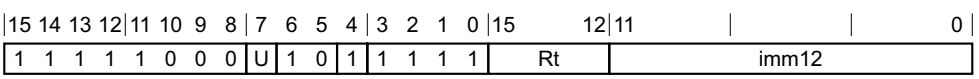
T1 variant

```
LDR{<c>}{<q>} <Rt>, <label> // Normal form
```

Decode for this encoding

```
t = UInt(Rt);  imm32 = ZeroExtend(imm8:'00', 32);  add = TRUE;
```

T2



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T2 variant

```
LDR{<c>}.W <Rt>, <label> // Preferred syntax, and <Rt>, <label> can be represented in T1
LDR{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDR{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative syntax
```

Decode for this encoding

```
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

`<label>` For encoding A1 and T2: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T2: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

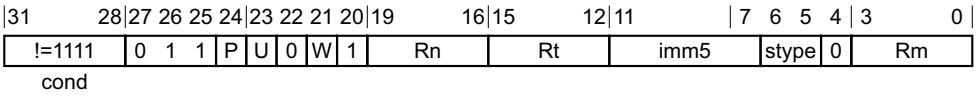
F5.1.74 LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see *Memory accesses* on page F2-3913.

The T32 form of LDR (register) does not support register writeback.

A1



Offset variant

Applies when P == 1 && W == 0.

```
LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]
```

Post-indexed variant

Applies when P == 0 && W == 0.

```
LDR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}
```

Pre-indexed variant

Applies when P == 1 && W == 1.

```
LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '1' then SEE "LDRT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Non-Confidential

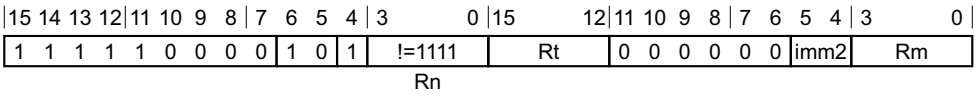
T1 variant

```
LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



T2 variant

```
LDR{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDR (literal)";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

`<Rn>` For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

`+/-` Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`+` Specifies the index register is added to the base register.

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see *Shifts applied to a register* on page F2-3911.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. `<imm>` is encoded in imm2. If absent, no shift is specified and imm2 is encoded as `0b00`.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
        offset_addr = if add then (R[n] + offset) else (R[n] - offset);
        address = if index then offset_addr else R[n];
        data = MemU[address,4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
        offset_addr = (R[n] + offset);
        address = offset_addr;
        data = MemU[address,4];
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
```

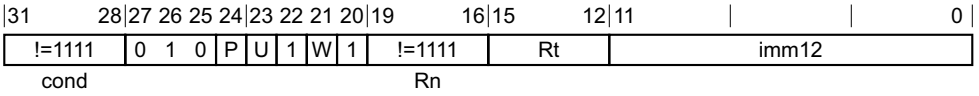
F5.1.75 LDRB (immediate)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

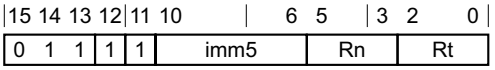
```
if Rn == '1111' then SEE "LDRB (literal)";
if P == '0' && W == '1' then SEE "LDRBT";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

```
LDRB{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

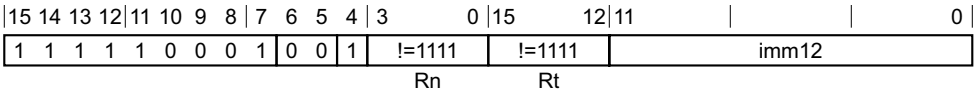
Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

T2



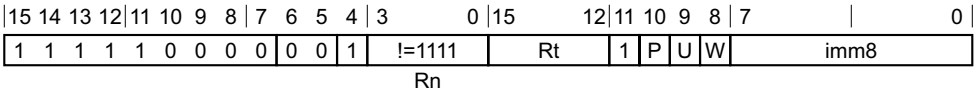
T2 variant

```
LDRB{<c>}.W <Rt>, [<Rn> {, #{+}<imm>}] // <Rt>, <Rn>, <imm> can be represented in T1
LDRB{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rt == '1111' then SEE "PLD";
if Rn == '1111' then SEE "LDRB (literal)";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
```

T3



Offset variant

Applies when `Rt != 1111 && P == 1 && U == 0 && W == 0`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 1`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "PLD, PLDW (immediate)";
if Rn == '1111' then SEE "LDRB (literal)";
if P == '1' && U == '1' && W == '0' then SEE "LDRBT";
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if  (t == 15 &&  W == '1') || (wback && n == t) then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` For encoding A1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRB (literal).

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        R[t] = ZeroExtend(MemU[address,1], 32);
        if wback then R[n] = offset_addr;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        R[t] = ZeroExtend(MemU[address,1], 32);
        if wback then R[n] = offset_addr;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = ZeroExtend(MemU[address,1], 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

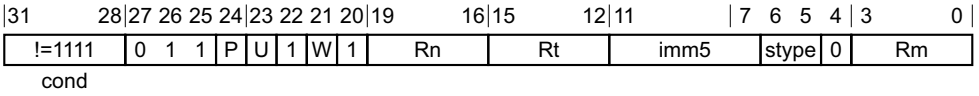
F5.1.77 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!
```

Decode for all variants of this encoding

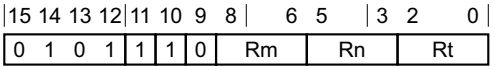
```
if P == '0' && W == '1' then SEE "LDRBT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

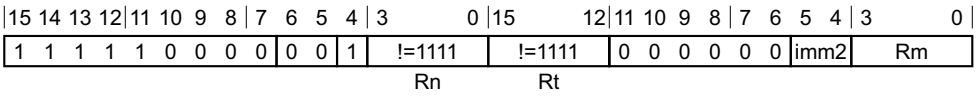
```
LDRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



T2 variant

```
LDRB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
LDRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]
```

Decode for this encoding

```
if Rt == '1111' then SEE "PLD";
if Rn == '1111' then SEE "LDRB (literal)";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

`+/-` Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`+` Specifies the index register is added to the base register.

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see *Shifts applied to a register* on page F2-3911.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. `<imm>` is encoded in imm2. If absent, no shift is specified and imm2 is encoded as `0b00`.

Non-Confidential

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1],32);
    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Non-Confidential

F5.1.78 LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

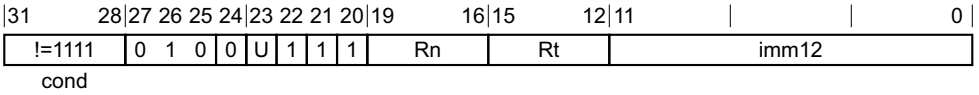
The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

`LDRBT` is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1



A1 variant

```
LDRBT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

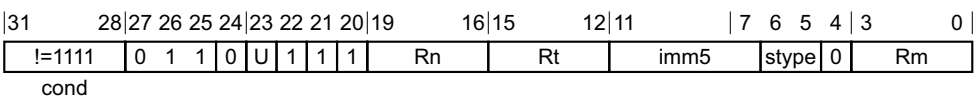
If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15* on page K1-7607.
- The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A2 variant

```
LDRBT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}
```

Decode for this encoding

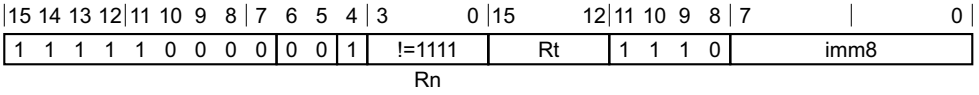
```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(stype, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

```
LDRBT{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDRB (literal)";
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding A2 and T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` Is the general-purpose base register, encoded in the "Rn" field.

`+/-` For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when `U = 0`

+ when `U = 1`

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see *Shifts applied to a register* on page F2-3911.

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = ZeroExtend(MemU_unpriv[address,1],32);
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRB` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

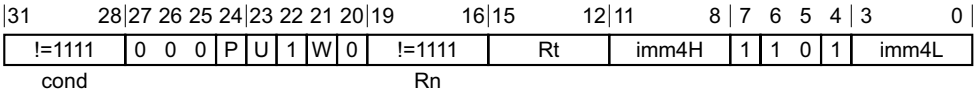
F5.1.79 LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE "LDRD (literal)";
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as an `LDRD` using one of offset, post-indexed, or pre-indexed addressing.

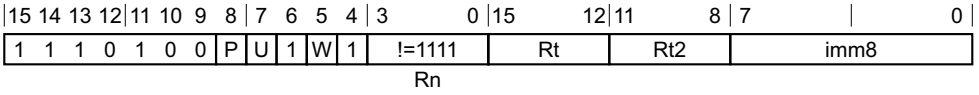
If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

T1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 1`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '0' then SEE "Related encodings";
if Rn == '1111' then SEE "LDRD (literal)";
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The load instruction executes but the destination register takes an UNKNOWN value.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Load/store dual, load/store exclusive, load-acquire/store-release, and table branch* on page F3-3975.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.

For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

`<Rt2>` For encoding A1: is the second general-purpose register to be transferred. This register must be `<R(t+1)>`.

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

`<Rn>` Is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRD (literal).

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the "imm8" field as <imm>/4.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian()  then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

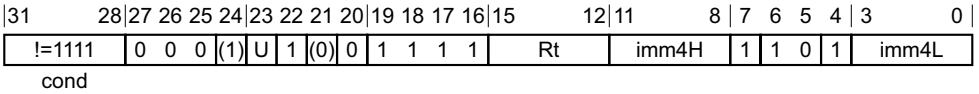
Non-Confidential

F5.1.80 LDRD (literal)

Load Register Dual (literal) calculates an address from the PC value and an immediate offset, loads two words from memory, and writes them to two registers. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



A1 variant

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // Normal form
LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #{+/-}<imm>] // Alternative form
```

Decode for this encoding

```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  imm32 = ZeroExtend(imm4H:imm4L, 32);  add = (U == '1');
if t2 == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

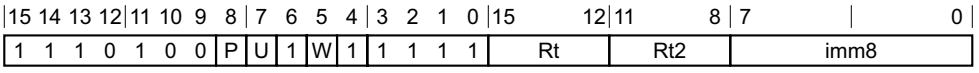
If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: t<0> = '0';.
- The instruction executes with the additional decode: t2 = t;.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

If `P == '0' || W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as if P == 1 and W == 0.'

T1



T1 variant

Applies when `!(P == 0 && W == 0)`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // Normal form
LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #{+/-}<imm>] // Alternative form
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if P == '0' && W == '0' then SEE "Related encodings";
t = UInt(Rt);  t2 = UInt(Rt2);
imm32 = ZeroExtend(imm8:'00', 32);  add = (U == '1');
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if W == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The load instruction executes but the destination register takes an UNKNOWN value.

If `W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15* on page K1-7607.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Load/store dual, load/store exclusive, load-acquire/store-release, and table branch* on page F3-3975.

Assembler symbols

`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rt>`	For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Rt2>`	For encoding A1: is the second general-purpose register to be transferred. This register must be `<R(t+1)>`. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<label>`	For encoding A1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1. If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0. For encoding T1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1. If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

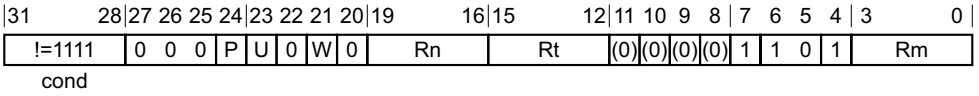
F5.1.81 LDRD (register)

Load Register Dual (register) calculates an address from a base register value and a register offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!
```

Decode for all variants of this encoding

```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if t2 == 15 || m == 15 || m == t || m == t2 then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as an `LDRD` using one of offset, post-indexed, or pre-indexed addressing.

If `m == t || m == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction loads register Rm with an UNKNOWN value.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.

`<Rt2>` Is the second general-purpose register to be transferred. This register must be `<R(t+1)>`.

`<Rn>` Is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

`+/-` Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];

    if wback then R[n] = offset_addr;
```

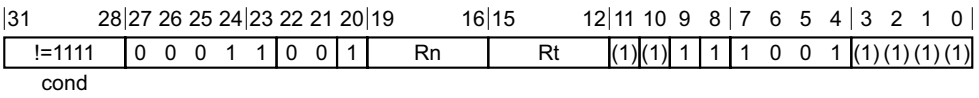
F5.1.82 LDREX

Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-3853. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



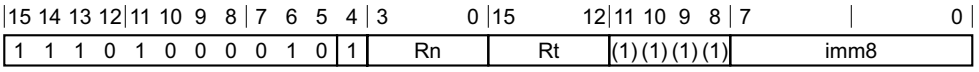
A1 variant

```
LDREX{<c>}{<q>} <Rt>, [<Rn> {, {#}<imm>}]
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  imm32 = Zeros(32); // Zero offset
if t == 15 || n == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
LDREX{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
if t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c>	See *Standard assembler syntax fields* on page F2-3908.
<q>	See *Standard assembler syntax fields* on page F2-3908.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<imm>	For encoding A1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For encoding T1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    AArch32.SetExclusiveMonitors(address,4);
    R[t] = MemA[address,4];
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

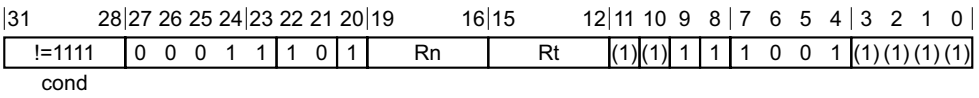
F5.1.83 LDREXB

Load Register Exclusive Byte derives an address from a base register value, loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-3853. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



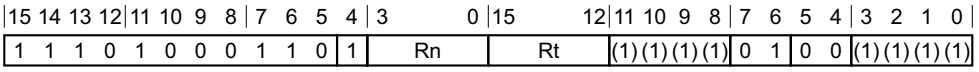
A1 variant

```
LDREXB{<c>}{<q>} <Rt>, [<Rn>]
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
LDREXB{<c>}{<q>} <Rt>, [<Rn>]
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c>	See *Standard assembler syntax fields* on page F2-3908.
<q>	See *Standard assembler syntax fields* on page F2-3908.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

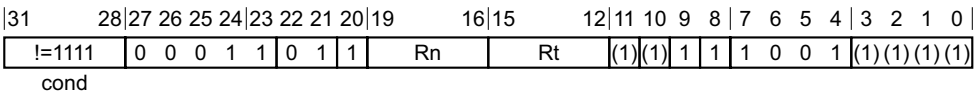
F5.1.84 LDREXD

Load Register Exclusive Doubleword derives an address from a base register value, loads a 64-bit doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-3853. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



A1 variant

```
LDREXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

Decode for this encoding

```
t = UInt(Rt);  t2 = t + 1;  n = UInt(Rn);
if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

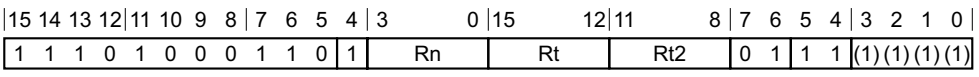
If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction is handled as described in *Using R15* on page K1-7607.

T1



T1 variant

```
LDREXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The load instruction executes but the destination register takes an UNKNOWN value.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rt>`	For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. `<Rt>` must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Rt2>`	For encoding A1: is the second general-purpose register to be transferred. `<Rt2>` must be `<R(t+1)>`. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Rn>`	Is the general-purpose base register, encoded in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,8);
    value = MemA[address,8];
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R[t]  = if BigEndian() then value<63:32> else value<31:0>;
    R[t2] = if BigEndian() then value<31:0> else value<63:32>;
```

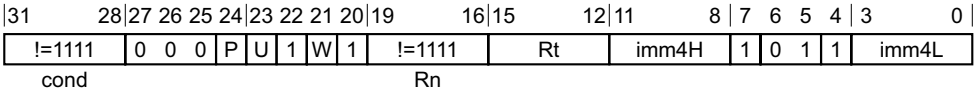
F5.1.86 LDRH (immediate)

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

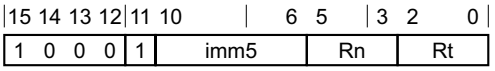
```
if Rn == '1111' then SEE "LDRH (literal)";
if P == '0' && W == '1' then SEE "LDRHT";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

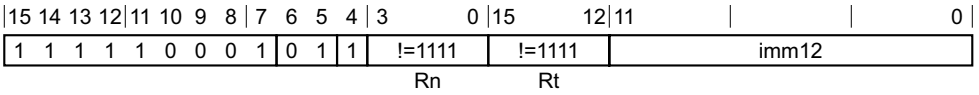
```
LDRH{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'0', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

T2



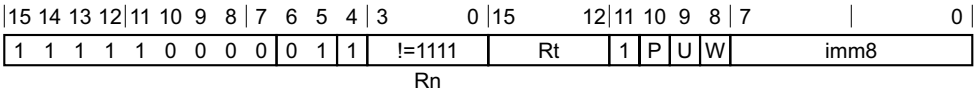
T2 variant

```
LDRH{<c>}.W <Rt>, [<Rn> {, #{+}<imm>}] // <Rt>, <Rn>, <imm> can be represented in T1
LDRH{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rt == '1111' then SEE "PLD (immediate)";
if Rn == '1111' then SEE "LDRH (literal)";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
```

T3



Offset variant

Applies when `Rt != 1111 && P == 1 && U == 0 && W == 0`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 1`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE "LDRH (literal)";
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "PLDW (immediate)";
if P == '1' && U == '1' && W == '0' then SEE "LDRHT";
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

Non-Confidential

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` For encoding A1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRH (literal).

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,2];
        if wback then R[n] = offset_addr;
        R[t] = ZeroExtend(data, 32);
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
data = MemU[address,2];
if wback then R[n] = offset_addr;
R[t] = ZeroExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

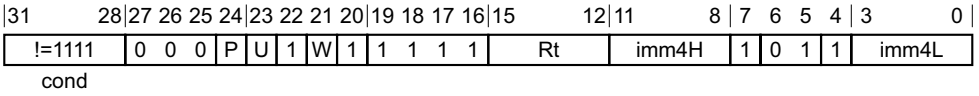
F5.1.87 LDRH (literal)

Load Register Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



A1 variant

Applies when `!(P == 0 && W == 1)`.

```
LDRH{<c>}{<q>} <Rt>, <label> // Normal form
LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative form
```

Decode for this encoding

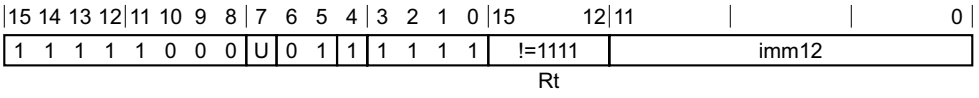
```
if P == '0' && W == '1' then SEE "LDRHT";
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRH (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15* on page K1-7607.

T1



T1 variant

```
LDRH{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative syntax
```

Decode for this encoding

```
if Rt == '1111' then SEE "PLD (literal)";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<label>` For encoding A1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1. If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = ZeroExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

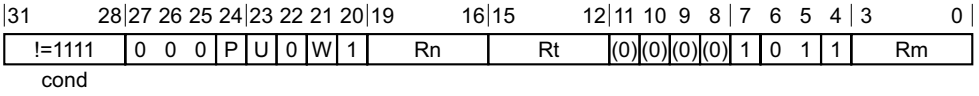
Non-Confidential

F5.1.88 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!
```

Decode for all variants of this encoding

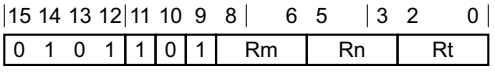
```
if P == '0' && W == '1' then SEE "LDRHT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

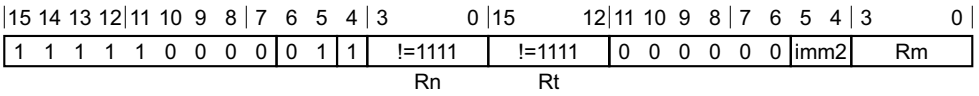
```
LDRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



T2 variant

```
LDRH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
LDRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDRH (literal)";
if Rt == '1111' then SEE "PLDW (register)";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

`+/-` Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`+` Specifies the index register is added to the base register.

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. `<imm>` is encoded in imm2. If absent, no shift is specified and imm2 is encoded as `0b00`.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
offset_addr = if add then (R[n] + offset) else (R[n] - offset);
address = if index then offset_addr else R[n];
data = MemU[address,2];
if wback then R[n] = offset_addr;
R[t] = ZeroExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Non-Confidential

F5.1.89 LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

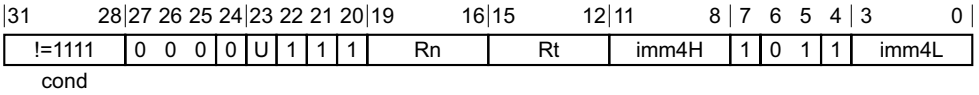
The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1



A1 variant

```
LDRHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15* on page K1-7607.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

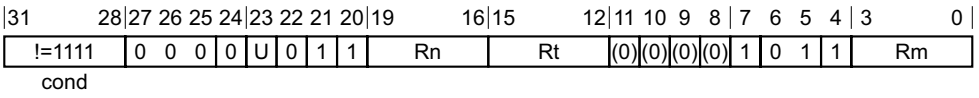
A2



A2 variant

```
LDRHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>
```

Decode for this encoding

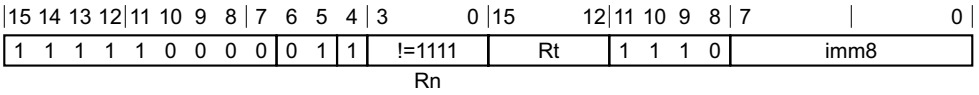
```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

```
LDRHT{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDRH (literal)";
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rt>`	Is the general-purpose register to be transferred, encoded in the "Rt" field.
`<Rn>`	Is the general-purpose base register, encoded in the "Rn" field.

Non-Confidential

`+/-` For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRH` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

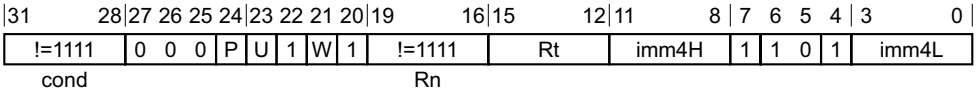
F5.1.90 LDRSB (immediate)

Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

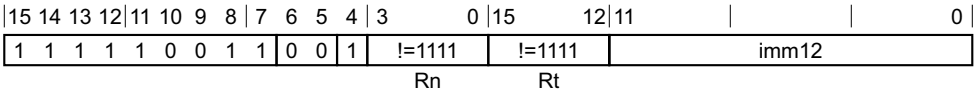
```
if Rn == '1111' then SEE "LDRSB (literal)";
if P == '0' && W == '1' then SEE "LDRSBT";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

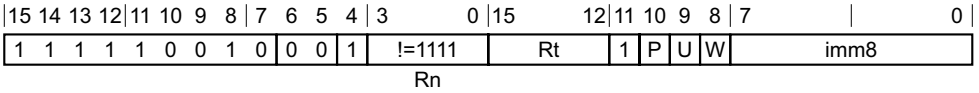
```
LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if Rt == '1111' then SEE "PLI";
if Rn == '1111' then SEE "LDRSB (literal)";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
```

T2



Offset variant

Applies when `Rt != 1111 && P == 1 && U == 0 && W == 0`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 1`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "PLI";
if Rn == '1111' then SEE "LDRSB (literal)";
if P == '1' && U == '1' && W == '0' then SEE "LDRSBT";
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` Is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRSB (literal).

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

Operational information

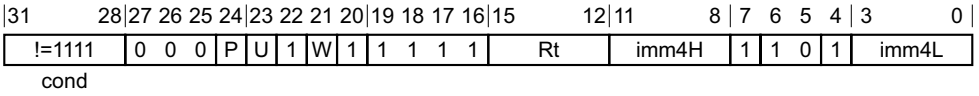
If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.91 LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



A1 variant

Applies when `!(P == 0 && W == 1)`.

```
LDRSB{<c>}{<q>} <Rt>, <label> // Normal form
LDRSB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative form
```

Decode for this encoding

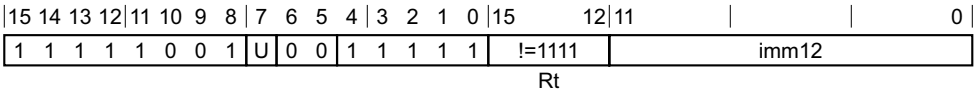
```
if P == '0' && W == '1' then SEE "LDRSBT";
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRSB (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15* on page K1-7607.

T1



T1 variant

```
LDRSB{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDRSB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative syntax
```

Decode for this encoding

```
if Rt == '1111' then SEE "PLI";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<label>` For encoding A1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1. If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = SignExtend(MemU[address,1], 32);
```

Operational information

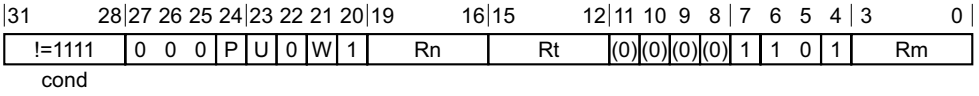
If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.92 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!
```

Decode for all variants of this encoding

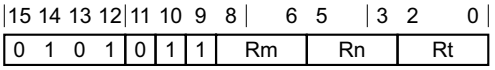
```
if P == '0' && W == '1' then SEE "LDRSBT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

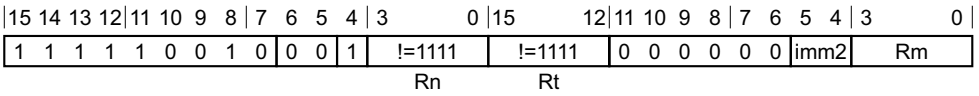
```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



T2 variant

```
LDRSB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]
```

Decode for this encoding

```
if Rt == '1111' then SEE "PLI";
if Rn == '1111' then SEE "LDRSB (literal)";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

`+/-` Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`+` Specifies the index register is added to the base register.

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. `<imm>` is encoded in imm2. If absent, no shift is specified and imm2 is encoded as `0b00`.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
offset_addr = if add then (R[n] + offset) else (R[n] - offset);
address = if index then offset_addr else R[n];
R[t] = SignExtend(MemU[address,1], 32);
if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

F5.1.93 LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

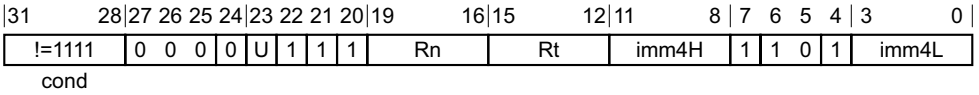
The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1



A1 variant

```
LDRSBT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15* on page K1-7607.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

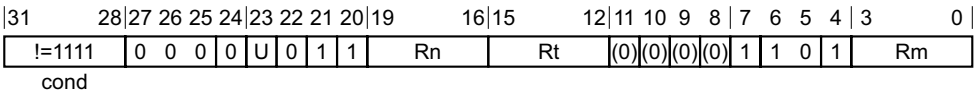
A2



A2 variant

```
LDRSBT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>
```

Decode for this encoding

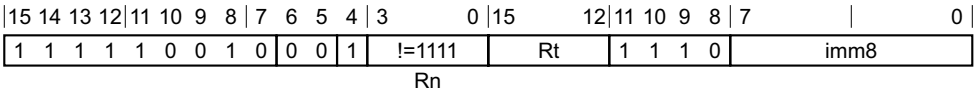
```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

```
LDRSBT{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDRSB (literal)";
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rt>`	Is the general-purpose register to be transferred, encoded in the "Rt" field.
`<Rn>`	Is the general-purpose base register, encoded in the "Rn" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`+/-` For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = SignExtend(MemU_unpriv[address,1], 32);
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRSB` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

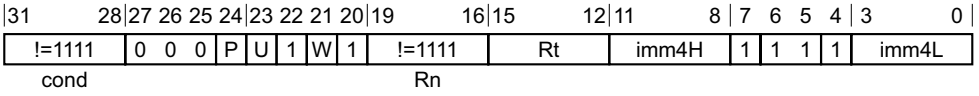
F5.1.94 LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

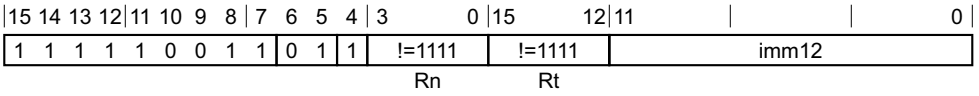
```
if Rn == '1111' then SEE "LDRSH (literal)";
if P == '0' && W == '1' then SEE "LDRSHT";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

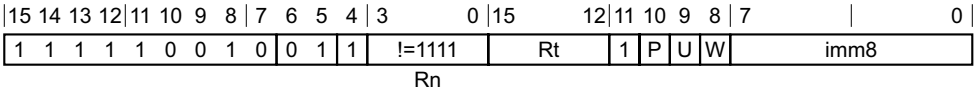
```
LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if Rn == '1111' then SEE "LDRSH (literal)";
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
```

T2



Offset variant

Applies when `Rt != 1111 && P == 1 && U == 0 && W == 0`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Post-indexed variant

Applies when `P == 0 && W == 1`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE "LDRSH (literal)";
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "Related instructions";
if P == '1' && U == '1' && W == '0' then SEE "LDRSHT";
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<Rn>` Is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRSH (literal).

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

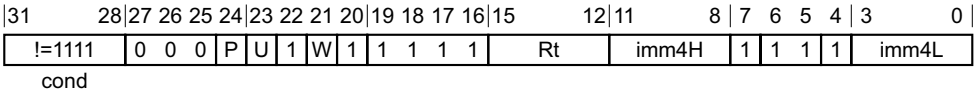
Non-Confidential

F5.1.95 LDRSH (literal)

Load Register Signed Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

A1



A1 variant

Applies when `!(P == 0 && W == 1)`.

```
LDRSH{<c>}{<q>} <Rt>, <label> // Normal form
LDRSH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative form
```

Decode for this encoding

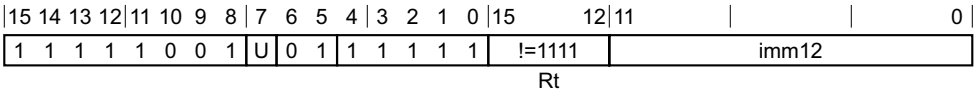
```
if P == '0' && W == '1' then SEE "LDRSHT";
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRSH (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15* on page K1-7607.

T1



T1 variant

```
LDRSH{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDRSH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative syntax
```

Decode for this encoding

```
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Related instructions: *Load, signed (literal)* on page F3-3996.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<label>` For encoding A1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1. If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add` == `TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add` == `FALSE`, encoded as U == 0.

`+/-` Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-3867.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = SignExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

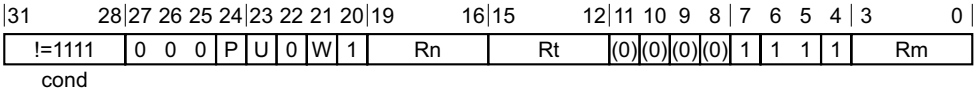
F5.1.96 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses on page F2-3913*.

A1



Offset variant

Applies when `P == 1 && W == 0`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]
```

Post-indexed variant

Applies when `P == 0 && W == 0`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>
```

Pre-indexed variant

Applies when `P == 1 && W == 1`.

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!
```

Decode for all variants of this encoding

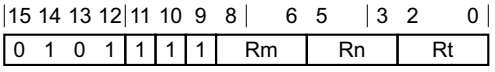
```
if P == '0' && W == '1' then SEE "LDRSHT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

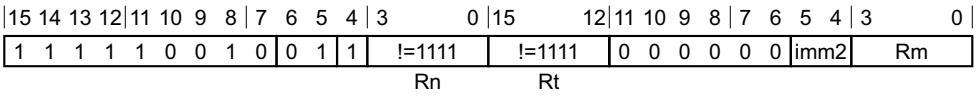
```
LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



T2 variant

```
LDRSH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDRSH (literal)";
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Related instructions: *Load/store, signed (register offset)* on page F3-3993.

Assembler symbols

<c>	See *Standard assembler syntax fields* on page F2-3908.
<q>	See *Standard assembler syntax fields* on page F2-3908.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant. For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1
+	Specifies the index register is added to the base register.
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

F5.1.97 LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

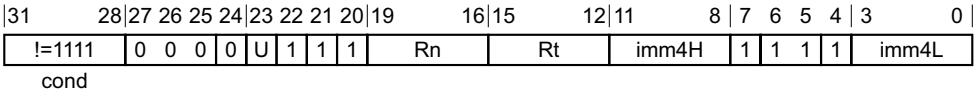
The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1



A1 variant

```
LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15* on page K1-7607.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

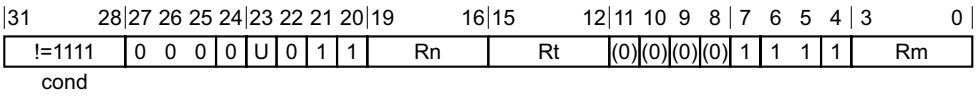
A2



A2 variant

```
LDRSHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>
```

Decode for this encoding

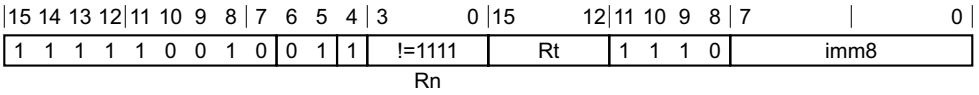
```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

```
LDRSHT{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDRSH (literal)";
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>`	See *Standard assembler syntax fields* on page F2-3908.
`<q>`	See *Standard assembler syntax fields* on page F2-3908.
`<Rt>`	Is the general-purpose register to be transferred, encoded in the "Rt" field.

`+/-` For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRSH` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

F5.1.98 LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-3913.

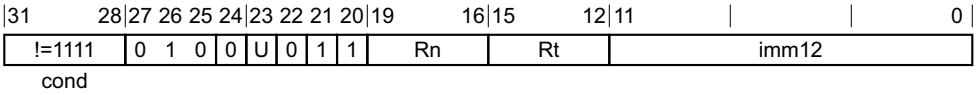
The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1



A1 variant

```
LDRT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

Decode for this encoding

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15* on page K1-7607.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

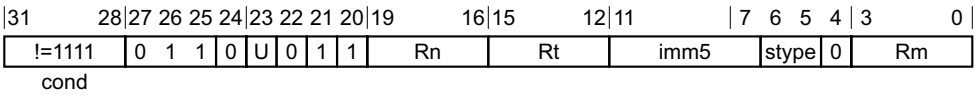
A2



A2 variant

```
LDRT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}
```

Decode for this encoding

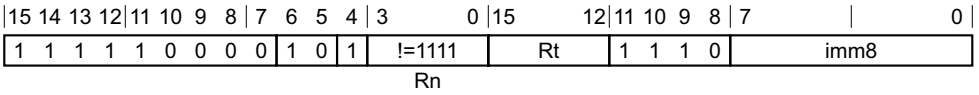
```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(stype, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1



T1 variant

```
LDRT{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then SEE "LDR (literal)";
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rt>` For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding A2 and T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Rn>` Is the general-purpose base register, encoded in the "Rn" field.

`+/-` For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- `-` when `U = 0`
- `+` when `U = 1`

`<Rm>` Is the general-purpose index register, encoded in the "Rm" field.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see *Shifts applied to a register* on page F2-3911.

`+` Specifies the offset is added to the base register.

`<imm>` For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,4];
    if postindex then R[n] = offset_addr;
    R[t] = data;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDR` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

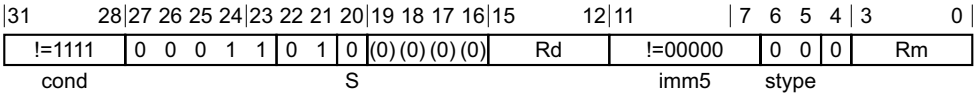
F5.1.99 LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

A1



MOV, shift or rotate by value variant

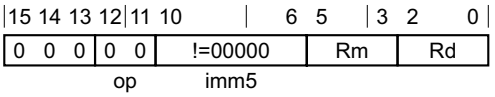
```
LSL{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>
```

and is always the preferred disassembly.

T2



T2 variant

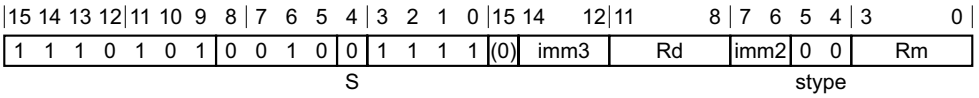
```
LSL<c>{<q>} {<Rd>,} <Rm>, #<imm> // Inside IT block
```

is equivalent to

```
MOV<c>{<q>} <Rd>, <Rm>, LSL #<imm>
```

and is the preferred disassembly when `InITBlock()`.

T3



MOV, shift or rotate by value variant

```
LSL<c>.W {<Rd>,} <Rm>, #<imm> // Inside IT block, and <Rd>, <Rm>, <imm> can be represented in T2
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>
```

and is always the preferred disassembly.

```
LSL{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>
```

and is always the preferred disassembly.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

`<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

`<imm>` For encoding A1: is the shift amount, in the range 0 to 31, encoded in the "imm5" field as <imm> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31, encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 0 to 31, encoded in the "imm3:imm2" field as <imm> modulo 32.

Operation for all encodings

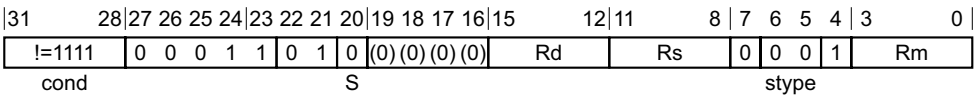
F5.1.100 LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register

This instruction is an alias of the MOV, MOVS (register-shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

A1



Not flag setting variant

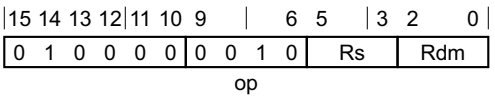
```
LSL{<c>}{<q>} {<Rd>,} <Rm>, <Rs>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSL <Rs>
```

and is always the preferred disassembly.

T1



Logical shift left variant

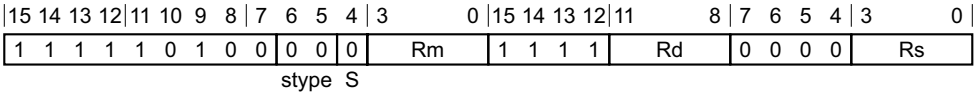
```
LSL<c>{<q>} {<Rdm>,} <Rdm>, <Rs> // Inside IT block
```

is equivalent to

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs>
```

and is the preferred disassembly when `InITBlock()`.

T2



Not flag setting variant

```
LSL<c>.W {<Rd>,} <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSL <Rs>
```

and is always the preferred disassembly.

F5.1.101 LSLS (immediate)

Logical Shift Left, setting flags (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

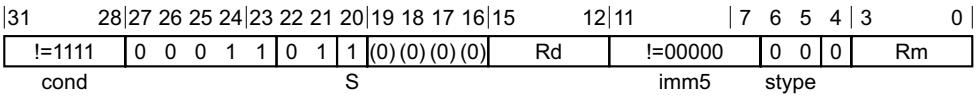
The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

A1



MOVS, shift or rotate by value variant

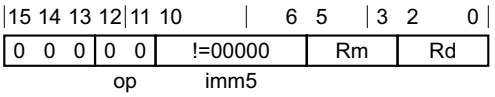
```
LSLS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>
```

and is always the preferred disassembly.

T2



T2 variant

```
LSLS{<q>} {<Rd>,} <Rm>, #<imm> // Outside IT block
```

is equivalent to

```
MOVS{<q>} <Rd>, <Rm>, LSL #<imm>
```

and is the preferred disassembly when `!InITBlock()`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

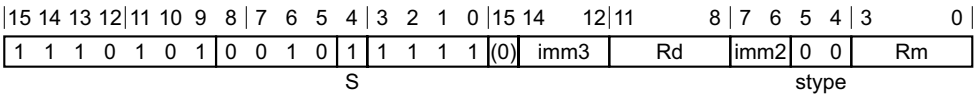
T3



MOVS, shift or rotate by value variant

`LSLS.W {<Rd>,} <Rm>, #<imm> // Outside IT block, and <Rd>, <Rm>, <imm> can be represented in T2`

is equivalent to

`MOVS{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>`

and is always the preferred disassembly.

`LSLS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>`

is equivalent to

`MOVS{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>`

and is always the preferred disassembly.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

`<Rm>` For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

`<imm>` For encoding A1: is the shift amount, in the range 0 to 31, encoded in the "imm5" field as <imm> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31, encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 0 to 31, encoded in the "imm3:imm2" field as <imm> modulo 32.

Operation for all encodings

F5.1.105 LSRS (immediate)

Logical Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

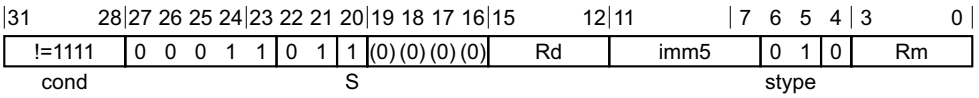
The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the MOV, MOVS (register) instruction. This means that:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

A1



MOVS, shift or rotate by value variant

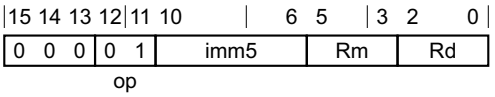
```
LSRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is always the preferred disassembly.

T2



T2 variant

```
LSRS{<q>} {<Rd>,} <Rm>, #<imm> // Outside IT block
```

is equivalent to

```
MOVS{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is the preferred disassembly when `!InITBlock()`.

`<Rs>`	Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation for all encodings

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.107 MCR

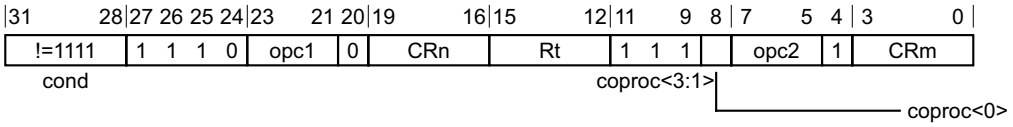
Move to System register from general-purpose register or execute a System instruction. This instruction copies the value of a general-purpose register to a System register, or executes a System instruction.

The System register and System instruction descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* on page E1-3805 and *General behavior of System registers* on page G8-5892.

In an implementation that includes EL2, MCR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable controls* on page G1-5585.

Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

A1



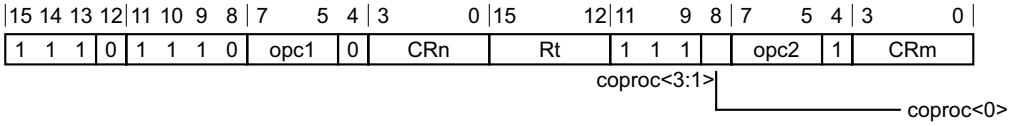
A1 variant

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

Decode for this encoding

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15  then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

T1



T1 variant

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

Decode for this encoding

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15  then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

`<coproc>` Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:

`p14` when `coproc<0> = 0`

`p15` when `coproc<0> = 1`

`<opc1>` Is the opc1 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc1" field.

`<Rt>` Is the general-purpose register to be transferred, encoded in the "Rt" field.

`<CRn>` Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.

`<CRm>` Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

`<opc2>` Is the opc2 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc2" field.

The possible values of { `<coproc>`, `<opc1>`, `<CRn>`, `<CRm>`, `<opc2>` } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.SysRegWrite(cp, ThisInstr(), R[t]);
```

F5.1.108 MCRR

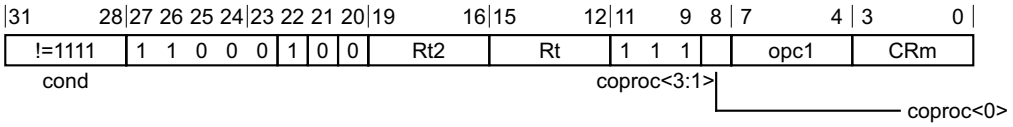
Move to System register from two general-purpose registers. This instruction copies the values of two general-purpose registers to a System register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* on page E1-3805 and *General behavior of System registers* on page G8-5892.

In an implementation that includes EL2, MCRR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCRR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable controls* on page G1-5585.

Because of the range of possible traps to Hyp mode, the MCRR pseudocode does not show these possible traps.

A1



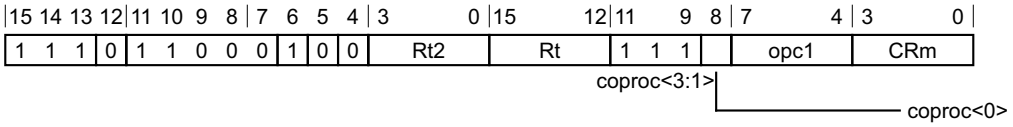
A1 variant

```
MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

Decode for this encoding

```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

T1



T1 variant

```
MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

Decode for this encoding

```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

Non-Confidential

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<coproc>` Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:

`p14` when `coproc<0> = 0`

`p15` when `coproc<0> = 1`

`<opc1>` Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.

`<Rt>` Is the first general-purpose register that is transferred into, encoded in the "Rt" field.

`<Rt2>` Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.

`<CRm>` Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of { `<coproc>`, `<opc1>`, `<CRm>` } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, `<Rt2>` transfers bits[63:32] of the selected System register, while `<Rt>` transfers bits[31:0].

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    value = R[t2]:R[t];
    AArch32.SysRegWrite64(cp, ThisInstr(), value);
```

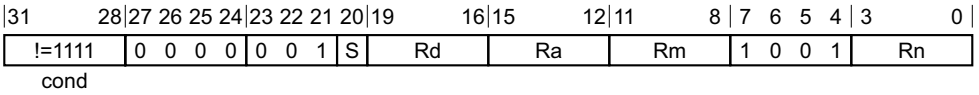
Non-Confidential

F5.1.109 MLA, MLAS

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

A1



Flag setting variant

Applies when `S == 1`.

```
MLAS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

Not flag setting variant

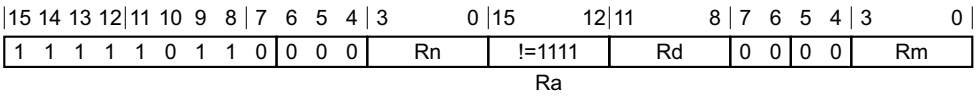
Applies when `S == 0`.

```
MLA{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
MLA{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

Decode for this encoding

```
if Ra == '1111' then SEE "MUL";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  setflags = FALSE;
if d == 15 || n == 15 || m  == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Rn>` Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

`<Rm>` Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

`<Ra>` Is the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = operand1 * operand2 + addend;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

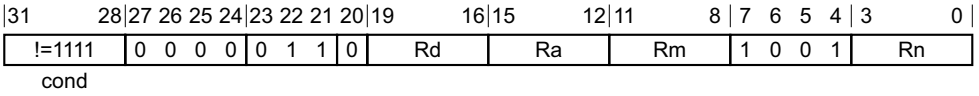
- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.110 MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

A1



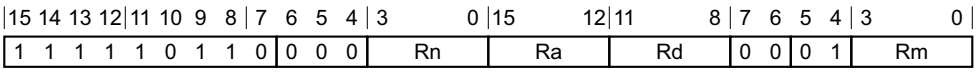
A1 variant

```
MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

Decode for this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

Decode for this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c>	See *Standard assembler syntax fields* on page F2-3908.
<q>	See *Standard assembler syntax fields* on page F2-3908.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Ra>	Is the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Non-Confidential

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = addend - operand1 * operand2;
    R[d] = result<31:0>;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

F5.1.111 MOV, MOVS (immediate)

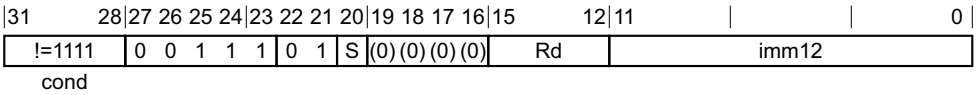
Move (immediate) writes an immediate value to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The MOV variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



MOV variant

Applies when S == 0.

```
MOV{<c>}{<q>} <Rd>, #<const>
```

MOVS variant

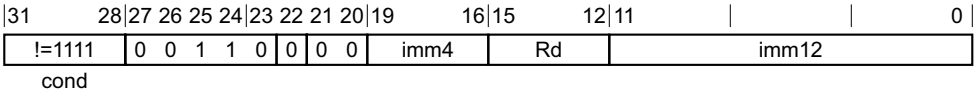
Applies when S == 1.

```
MOVS{<c>}{<q>} <Rd>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  setflags = (S == '1');  (imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

A2



A2 variant

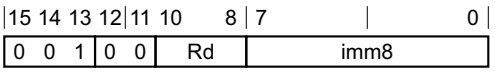
```
MOV{<c>}{<q>} <Rd>, #<imm16> // <imm16> can not be represented in A1
MOVW{<c>}{<q>} <Rd>, #<imm16> // <imm16> can be represented in A1
```

Decode for this encoding

```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm4:imm12, 32);
if d == 15 then UNPREDICTABLE;
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1



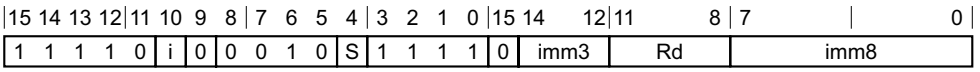
T1 variant

```
MOV<c>{<q>} <Rd>, #<imm8> // Inside IT block
MOVS{<q>} <Rd>, #<imm8> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rd);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);  carry = PSTATE.C;
```

T2



MOV variant

Applies when `S == 0`.

```
MOV<c>.W <Rd>, #<const> // Inside IT block, and <Rd>, <const> can be represented in T1
MOV{<c>}{<q>} <Rd>, #<const>
```

MOVS variant

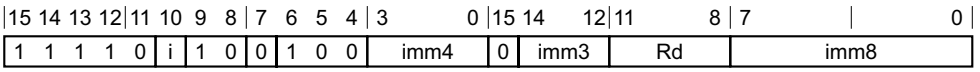
Applies when `S == 1`.

```
MOVS.W <Rd>, #<const> // Outside IT block, and <Rd>, <const> can be represented in T1
MOVS{<c>}{<q>} <Rd>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  setflags = (S == '1');  (imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

T3



T3 variant

```
MOV{<c>}{<q>} <Rd>, #<imm16> // <imm16> cannot be represented in T1 or T2
MOVW{<c>}{<q>} <Rd>, #<imm16> // <imm16> can be represented in T1 or T2
```

Decode for this encoding

```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm4:i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding A2, T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<imm8> Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<imm16> For encoding A2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.

For encoding T3: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T2: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = imm32;
    if d == 15 then          // Can only occur for encoding A1
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.112 MOV, MOVS (register)

Move (register) copies a value from a register to the destination register.

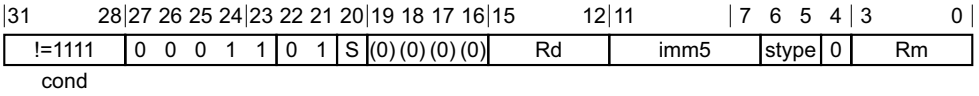
If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The MOV variant of the instruction is a branch. In the T32 instruction set (encoding T1) this is a simple branch, and in the A32 instruction set it is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is used by the aliases ASRS (immediate), ASR (immediate), LSLS (immediate), LSL (immediate), LSRS (immediate), LSR (immediate), RORS (immediate), ROR (immediate), RRXS, and RRX. See *Alias conditions* on page F5-4345 for details of when each alias is preferred.

A1



MOV, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
MOV{<c>}{<q>} <Rd>, <Rm>, RRX
```

MOV, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
MOV{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

MOVS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
MOVS{<c>}{<q>} <Rd>, <Rm>, RRX
```

MOVS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

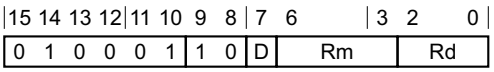
```
MOVS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T1



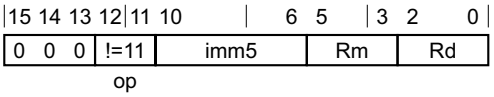
T1 variant

```
MOV{<c>}{<q>} <Rd>, <Rm>
```

Decode for this encoding

```
d = UInt(D:Rd);  m = UInt(Rm);  setflags = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

T2



T2 variant

```
MOV<c>{<q>} <Rd>, <Rm> {, <shift> #<amount>} // Inside IT block
MOVS{<q>} <Rd>, <Rm> {, <shift> #<amount>} // Outside IT block
```

Decode for this encoding

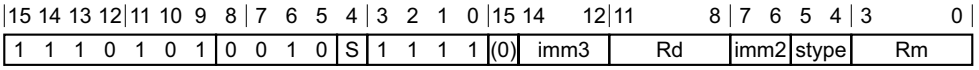
```
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = DecodeImmShift(op, imm5);
if op == '00' && imm5 == '00000' && InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `op == '00' && imm5 == '00000' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passed its condition code check.
- The instruction executes as `NOP`, as if it failed its condition code check.
- The instruction executes as `MOV` Rd, Rm.

T3



MOV, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
MOV{<c>}{<q>} <Rd>, <Rm>, RRX
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MOV, shift or rotate by value variant

Applies when S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11).

```
MOV{<c>}.W <Rd>, <Rm> {, LSL #0} // <Rd>, <Rm> can be represented in T1
MOV<c>.W <Rd>, <Rm> {, <shift> #<amount>} // Inside IT block, and <Rd>, <Rm>, <shift>, <amount> can be
represented in T2
MOV{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

MOVS, rotate right with extend variant

Applies when S == 1 && imm3 == 000 && imm2 == 00 && stype == 11.

```
MOVS{<c>}{<q>} <Rd>, <Rm>, RRX
```

MOVS, shift or rotate by value variant

Applies when S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11).

```
MOVS.W <Rd>, <Rm> {, <shift> #<amount>} // Outside IT block, and <Rd>, <Rm>, <shift>, <amount> can be
represented in T1 or T2
MOVS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Alias conditions

Alias	of variant	is preferred when
ASRS (immediate)	T3 (MOVS, shift or rotate by value), A1 (MOVS, shift or rotate by value)	`S == '1' && stype == '10'`
ASRS (immediate)	T2	`op == '10' && !InITBlock()`
ASR (immediate)	T3 (MOV, shift or rotate by value), A1 (MOV, shift or rotate by value)	`S == '0' && stype == '10'`
ASR (immediate)	T2	`op == '10' && InITBlock()`
LSLS (immediate)	T3 (MOVS, shift or rotate by value)	`S == '1' && imm3:Rd:imm2 != '000xxxx00' && stype == '00'`
LSLS (immediate)	A1 (MOVS, shift or rotate by value)	`S == '1' && imm5 != '00000' && stype == '00'`
LSLS (immediate)	T2	`op == '00' && imm5 != '00000' && !InITBlock()`

RRX	T3 (MOV, rotate right with extend)	`S == '0' && imm3 == '000' && imm2 == '00' && stype == '11'`
RRX	A1 (MOV, rotate right with extend)	`S == '0' && imm5 == '00000' && stype == '11'`

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rd>` For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787. Arm deprecates use of the instruction if `<Rn>` is the PC.
- For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of the instruction if <Rn> is not the LR, or if the optional shift or `RRX` argument is specified.

For encoding T1: is the general-purpose destination register, encoded in the "D:Rd" field. If the PC is used:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The instruction must either be outside an IT block or the last instruction of an IT block.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

`<Rm>` For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used. Arm deprecates use of the instruction if `<Rd>` is the PC.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

`<shift>` For encoding A1 and T3: is the type of shift to be applied to the source register, encoded in the "stype" field. It can have the following values:

`LSL` when `stype = 00`

`LSR` when `stype = 01`

`ASR` when `stype = 10`

`ROR` when `stype = 11`

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For encoding T2: is the type of shift to be applied to the source register, encoded in the "op" field. It can have the following values:

`LSL` when `op = 00`

`LSR` when `op = 01`

`ASR` when `op = 10`

`<amount>` For encoding A1: is the shift amount, in the range 0 to 31 (when <shift> = LSL), or 1 to 31 (when <shift> = ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 0 to 31 (when <shift> = LSL) or 1 to 31 (when <shift> = ROR), or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = shifted;
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

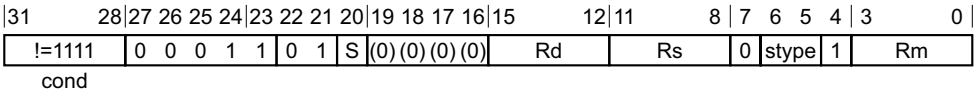
F5.1.113 MOV, MOVS (register-shifted register)

Move (register-shifted register) copies a register-shifted register value to the destination register. It can optionally update the condition flags based on the value.

This instruction is used by the aliases ASRS (register), ASR (register), LSLS (register), LSL (register), LSRS (register), LSR (register), RORS (register), and ROR (register). See *Alias conditions* on page F5-4350 for details of when each alias is preferred.

A1



Flag setting variant

Applies when `S == 1`.

```
MOVS{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Not flag setting variant

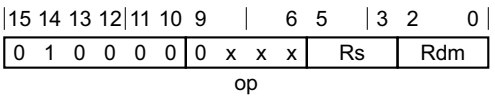
Applies when `S == 0`.

```
MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

T1



Arithmetic shift right variant

Applies when `op == 0100`.

```
MOV<c>{<q>} <Rdm>, <Rdm>, ASR <Rs> // Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, ASR <Rs> // Outside IT block
```

Logical shift left variant

Applies when `op == 0010`.

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs> // Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, LSL <Rs> // Outside IT block
```

Logical shift right variant

Applies when `op == 0011`.

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs> // Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, LSR <Rs> // Outside IT block
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Rotate right variant

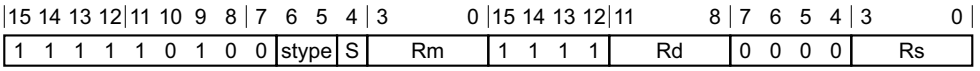
Applies when op == 0111.

```
MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs> // Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, ROR <Rs> // Outside IT block
```

Decode for all variants of this encoding

```
if !(op IN {'0010', '0011', '0100', '0111'}) then SEE "Related encodings";
d = UInt(Rdm);  m = UInt(Rdm);  s = UInt(Rs);
setflags = !InITBlock();  shift_t = DecodeRegShift(op<2>:op<0>);
```

T2



Flag setting variant

Applies when S == 1.

```
MOVS.W <Rd>, <Rm>, <shift> <Rs> // Outside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in
T1
MOVS{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Not flag setting variant

Applies when S == 0.

```
MOV<c>.W <Rd>, <Rm>, <shift> <Rs> // Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in
T1
MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

Related encodings: In encoding T1, for an op field value that is not described above, see *Data-processing (two low registers)* on page F3-3937.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

ROR (register)	T2 (not flag setting)	`stype == '11' && S == '0'`

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<Rdm>` Is the general-purpose source register and the destination register, encoded in the "Rdm" field.

`<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.

`<Rm>` Is the general-purpose source register, encoded in the "Rm" field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<shift> Is the type of shift to be applied to the second source register, encoded in the "stype" field. It can have the following values:

LSL when stype = 00

LSR when stype = 01

ASR when stype = 10

ROR when stype = 11

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (result, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

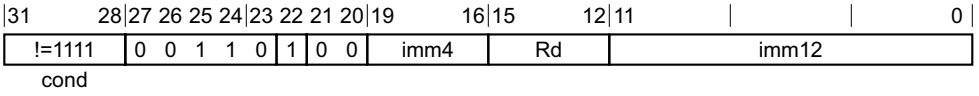
F5.1.114 MOVT

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

A1



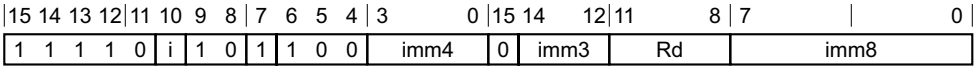
A1 variant

```
MOVT{<c>}{<q>} <Rd>, #<imm16>
```

Decode for this encoding

```
d = UInt(Rd);  imm16 = imm4:imm12;
if d == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
MOVT{<c>}{<q>} <Rd>, #<imm16>
```

Decode for this encoding

```
d = UInt(Rd);  imm16 = imm4:i:imm3:imm8;
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c>	See *Standard assembler syntax fields* on page F2-3908.
<q>	See *Standard assembler syntax fields* on page F2-3908.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<imm16>	For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

F5.1.115 MRC

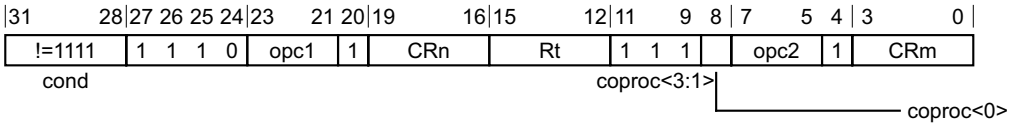
Move to general-purpose register from System register. This instruction copies the value of a System register to a general-purpose register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* on page E1-3805 and *General behavior of System registers* on page G8-5892.

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable controls* on page G1-5585.

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

A1



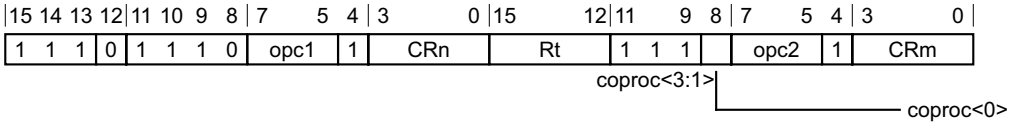
A1 variant

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

Decode for this encoding

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

T1



T1 variant

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

Decode for this encoding

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<coproc> Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:

p14 when coproc<0> = 0

p15 when coproc<0> = 1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<opc1>` Is the opc1 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc1" field.

`<Rt>` Is the general-purpose register to be transferred or `APSR_nzcv` (encoded as `0b1111`), encoded in the "Rt" field. If `APSR_nzcv` is used, bits [31:28] of the transferred value are written to the PSTATE condition flags.

`<CRn>` Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.

`<CRm>` Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

`<opc2>` Is the opc2 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc2" field.

The possible values of { `<coproc>`, `<opc1>`, `<CRn>`, `<CRm>`, `<opc2>` } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) value = AArch32.SysRegRead(cp, ThisInstr());
    if t != 15 then
        R[t] = value;
    elsif AArch32.SysRegReadCanWriteAPSR(cp, ThisInstr()) then
        PSTATE.<N,Z,C,V> = value<31:28>;
        // value<27:0> are not used.
    else
        PSTATE.<N,Z,C,V> = bits(4) UNKNOWN;
```

Non-Confidential

F5.1.116 MRRC

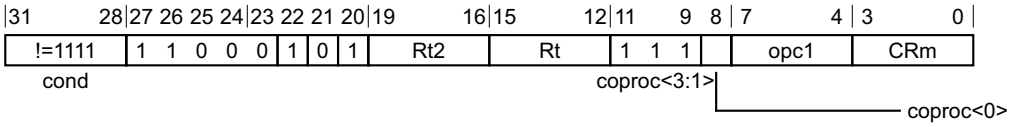
Move to two general-purpose registers from System register. This instruction copies the value of a System register to two general-purpose registers.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* on page E1-3805 and *General behavior of System registers* on page G8-5892.

In an implementation that includes EL2, MRRC accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MRRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable controls* on page G1-5585.

Because of the range of possible traps to Hyp mode, the MRRC pseudocode does not show these possible traps.

A1



A1 variant

```
MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

Decode for this encoding

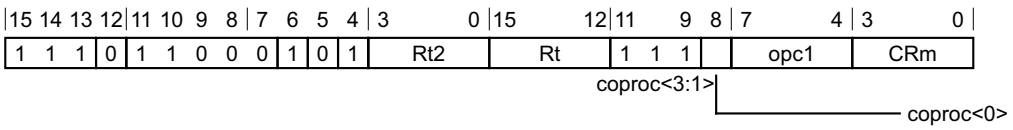
```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1



T1 variant

```
MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

Decode for this encoding

```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<coproc>` Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:

`p14` when `coproc<0> = 0`

`p15` when `coproc<0> = 1`

`<opc1>` Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.

`<Rt>` Is the first general-purpose register that is transferred into, encoded in the "Rt" field.

`<Rt2>` Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.

`<CRm>` Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of { `<coproc>`, `<opc1>`, `<CRm>` } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, `<Rt2>` transfers bits[63:32] of the selected System register, while `<Rt>` transfers bits[31:0].

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    value = AArch32.SysRegRead64(cp, ThisInstr());
    R[t] = value<31:0>;
    R[t2] = value<63:32>;
```

F5.1.117 MRS

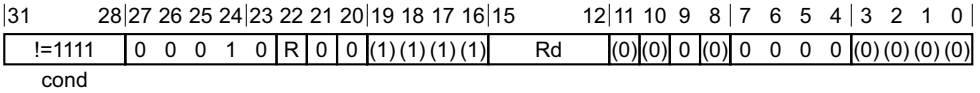
Move Special register to general-purpose register moves the value of the *The Application Program Status Register, APSR* on page E1-3789, CPSR, or SPSR_<current_mode> into a general-purpose register.

Arm recommends the APSR form when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register, APSR* on page E1-3789.

An MRS that accesses the SPSR is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the CPSR returns an UNKNOWN value for the CPSR.{E, A, I, F, M} fields.

A1



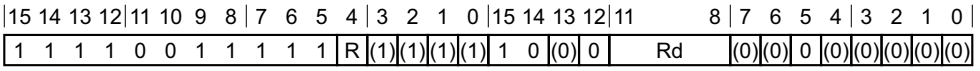
A1 variant

```
MRS{<c>}{<q>} <Rd>, <spec_reg>
```

Decode for this encoding

```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE;
```

T1



T1 variant

```
MRS{<c>}{<q>} <Rd>, <spec_reg>
```

Decode for this encoding

```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<spec_reg> Is the special register to be accessed, encoded in the "R" field. It can have the following values:

CPSR|APSR when R = 0

SPSR when R = 1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if read_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            R[d] = SPSR[];
    else
        // CPSR has same bit assignments as SPSR, but with the IT, J, SS, IL, and T bits masked out.
        bits(32) mask = '11111000 00001111 00000011 11011111';
        if HavePANExt() then
            mask<22> = '1';
        psr_val = GetPSRFromPSTATE() AND mask;
        if PSTATE.EL == EL0 then
            // If accessed from User mode return UNKNOWN values for E, A, I, F bits, bits<9:6>,
            // and for the M field, bits<4:0>
            psr_val<22> = bits(1) UNKNOWN;
            psr_val<9:6> = bits(4) UNKNOWN;
            psr_val<4:0> = bits(5) UNKNOWN;
        R[d] = psr_val;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User, M32_System} && read_spsr`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

F5.1.118 MRS (Banked register)

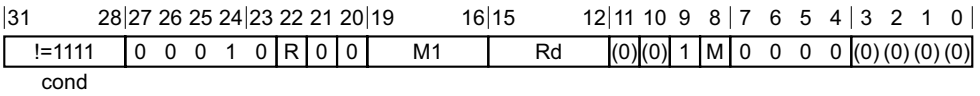
Move to Register from Banked or Special register moves the value from the Banked general-purpose register or SPSR of the specified mode, or the value of *ELR_hyp* on page G1-5492, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MRS (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the banked register transfer instructions* on page F5-4778.

A1



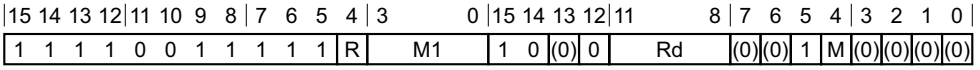
A1 variant

```
MRS{<c>}{<q>} <Rd>, <banked_reg>
```

Decode for this encoding

```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE;
SYSm = M:M1;
```

T1



T1 variant

```
MRS{<c>}{<q>} <Rd>, <banked_reg>
```

Decode for this encoding

```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
SYSm = M:M1;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

Non-Confidential

<banked_reg> Is the name of the banked register to be transferred to or from, encoded in the "R:M:M1" field. It can have the following values:

R8_usr	when R = 0, M = 0, M1 = 0000
R9_usr	when R = 0, M = 0, M1 = 0001
R10_usr	when R = 0, M = 0, M1 = 0010
R11_usr	when R = 0, M = 0, M1 = 0011
R12_usr	when R = 0, M = 0, M1 = 0100
SP_usr	when R = 0, M = 0, M1 = 0101
LR_usr	when R = 0, M = 0, M1 = 0110
R8_fiq	when R = 0, M = 0, M1 = 1000
R9_fiq	when R = 0, M = 0, M1 = 1001
R10_fiq	when R = 0, M = 0, M1 = 1010
R11_fiq	when R = 0, M = 0, M1 = 1011
R12_fiq	when R = 0, M = 0, M1 = 1100
SP_fiq	when R = 0, M = 0, M1 = 1101
LR_fiq	when R = 0, M = 0, M1 = 1110
LR_irq	when R = 0, M = 1, M1 = 0000
SP_irq	when R = 0, M = 1, M1 = 0001
LR_svc	when R = 0, M = 1, M1 = 0010
SP_svc	when R = 0, M = 1, M1 = 0011
LR_abt	when R = 0, M = 1, M1 = 0100
SP_abt	when R = 0, M = 1, M1 = 0101
LR_und	when R = 0, M = 1, M1 = 0110
SP_und	when R = 0, M = 1, M1 = 0111
LR_mon	when R = 0, M = 1, M1 = 1100
SP_mon	when R = 0, M = 1, M1 = 1101
ELR_hyp	when R = 0, M = 1, M1 = 1110
SP_hyp	when R = 0, M = 1, M1 = 1111
SPSR_fiq	when R = 1, M = 0, M1 = 1110
SPSR_irq	when R = 1, M = 1, M1 = 0000
SPSR_svc	when R = 1, M = 1, M1 = 0010
SPSR_abt	when R = 1, M = 1, M1 = 0100
SPSR_und	when R = 1, M = 1, M1 = 0110
SPSR_mon	when R = 1, M = 1, M1 = 1100
SPSR_hyp	when R = 1, M = 1, M1 = 1110

The following encodings are UNPREDICTABLE:

- R = 0, M = 0, M1 = 0111.
- R = 0, M = 0, M1 = 1111.
- R = 0, M = 1, M1 = 10xx.
- R = 1, M = 0, M1 = 0xxx.
- R = 1, M = 0, M1 = 10xx.
- R = 1, M = 0, M1 = 110x.
- R = 1, M = 0, M1 = 1111.
- R = 1, M = 1, M1 = 0001.

F5.1.119 MSR (Banked register)

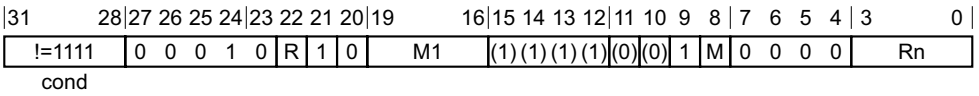
Move to Banked or Special register from general-purpose register moves the value of a general-purpose register to the Banked general-purpose register or SPSR of the specified mode, or to *ELR_hyp* on page G1-5492.

MSR (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MSR (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MSR (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the banked register transfer instructions* on page F5-4778.

A1



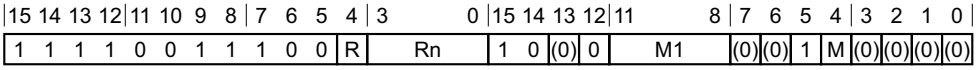
A1 variant

```
MSR{<c>}{<q>} <banked_reg>, <Rn>
```

Decode for this encoding

```
n = UInt(Rn);  write_spsr = (R == '1');
if n == 15 then UNPREDICTABLE;
SYSm = M:M1;
```

T1



T1 variant

```
MSR{<c>}{<q>} <banked_reg>, <Rn>
```

Decode for this encoding

```
n = UInt(Rn);  write_spsr = (R == '1');
if n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
SYSm = M:M1;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F5.1.120 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the *The Application Program Status Register, APSR* on page E1-3789, CPSR, or SPSR_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, the immediate form of MSR is normally only useful at the Application level for writing to APSR_nzcvq (CPSR_f).

If an MSR (immediate) moves selected bits of an immediate value to the CPSR, the PE checks whether the value being written to PSTATE.M is legal. See *Illegal changes to PSTATE.M* on page G1-5497.

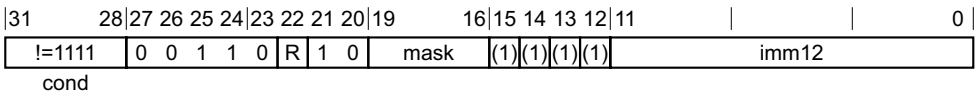
An MSR (immediate) executed in User mode:

- Is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher,

An MSR (immediate) executed in System mode is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.

The CPSR.E bit is writable from any mode using an MSR instruction. Arm deprecates using this to change its value.

A1



A1 variant

Applies when !(R == 0 && mask == 0000).

```
MSR{<c>}{<q>} <spec_reg>, #<imm>
```

Decode for this encoding

```
if mask == '0000' && R == '0' then SEE "Related encodings";
imm32 = A32ExpandImm(imm12);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000' && R == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Move Special Register and Hints (immediate)* on page F4-4021.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<spec_reg> Is one of:

- APSR_<bits>.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- CPSR_<fields>.
- SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.

x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.

s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.

f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvq, g, or nzcvqg. These map to the following CPSR_<fields> values:

- APSR_nzcvq is the same as CPSR_f (mask== '1000').
- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvqg is the same as CPSR_fs (mask == '1100').

Arm recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register, APSR* on page E1-3789.

<imm> Is an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            SPSRWriteByInstr(imm32, mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(imm32, mask);
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System} && write_spsr, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.121 MSR (register)

Move general-purpose register to Special register moves selected bits of a general-purpose register to the *The Application Program Status Register, APSR* on page E1-3789, CPSR or SPSR_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally required when the MSR instruction is being used at Application level and its destination is not APSR_nzcvq (CPSR_f).

If an MSR (register) moves selected bits of an immediate value to the CPSR, the PE checks whether the value being written to PSTATE.M is legal. See *Illegal changes to PSTATE.M* on page G1-5497.

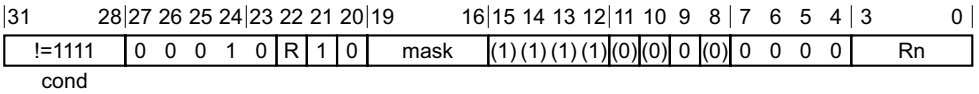
An MSR (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the SPSR.

The CPSR.E bit is writable from any mode using an MSR instruction. Arm deprecates using this to change its value.

A1



A1 variant

```
MSR{<c>}{<q>} <spec_reg>, <Rn>
```

Decode for this encoding

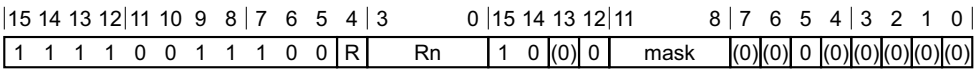
```
n = UInt(Rn);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

T1



T1 variant

```
MSR{<c>}{<q>} <spec_reg>, <Rn>
```

Decode for this encoding

```
n = UInt(Rn);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Non-Confidential

CONSTRAINED UNPREDICTABLE behavior

If `mask == '0000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<c>` See *Standard assembler syntax fields* on page F2-3908.

`<q>` See *Standard assembler syntax fields* on page F2-3908.

`<spec_reg>` Is one of:

- `APSR_<bits>`.
- `CPSR_<fields>`.
- `SPSR_<fields>`.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

`c` mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.

`x` mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.

`s` mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.

`f` mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of `nzcvq`, `g`, or `nzcvqg`. These map to the following CPSR_<fields> values:

- `APSR_nzcvq` is the same as `CPSR_f` (mask== '1000').
- `APSR_g` is the same as `CPSR_s` (mask == '0100').
- `APSR_nzcvqg` is the same as `CPSR_fs` (mask == '1100').

Arm recommends the `APSR_<bits>` forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register, APSR* on page E1-3789.

`<Rn>` Is the general-purpose source register, encoded in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            SPSRWriteByInstr(R[n], mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(R[n], mask);
```

CONSTRAINED UNPREDICTABLE behavior

If `write_spsr && PSTATE.M IN {M32_User,M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction executes as `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

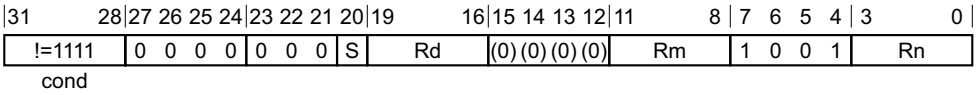
F5.1.122 MUL, MULS

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

A1



Flag setting variant

Applies when `S == 1`.

```
MULS{<c>}{<q>} <Rd>, <Rn>{, <Rm>}
```

Not flag setting variant

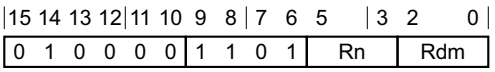
Applies when `S == 0`.

```
MUL{<c>}{<q>} <Rd>, <Rn>{, <Rm>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1



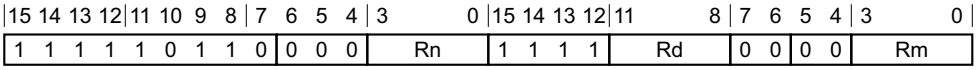
T1 variant

```
MUL<c>{<q>} <Rdm>, <Rn>{, <Rdm>} // Inside IT block
MULS{<q>} <Rdm>, <Rn>{, <Rdm>} // Outside IT block
```

Decode for this encoding

```
d = UInt(Rdm);  n = UInt(Rn);  m = UInt(Rdm);  setflags = !InITBlock();
```

T2



T2 variant

```
MUL<c>.W <Rd>, <Rn>{, <Rm>} // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
MUL{<c>}{<q>} <Rd>, <Rn>{, <Rm>}
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c>	See *Standard assembler syntax fields* on page F2-3908.
<q>	See *Standard assembler syntax fields* on page F2-3908.
<Rdm>	Is the second general-purpose source register holding the multiplier and the destination register, encoded in the "Rdm" field.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field. If omitted, <Rd> is used.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    result = operand1 * operand2;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

F5.1.123 MVN, MVNS (immediate)

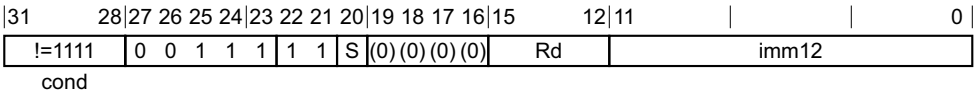
Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



MVN variant

Applies when S == 0.

```
MVN{<c>}{<q>} <Rd>, #<const>
```

MVNS variant

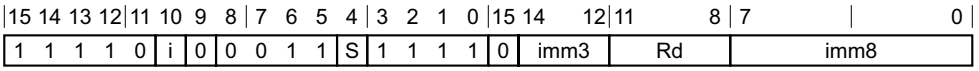
Applies when S == 1.

```
MVNS{<c>}{<q>} <Rd>, #<const>
```

Decode for all variants of this encoding

```
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1



MVN variant

Applies when S == 0.

```
MVN{<c>}{<q>} <Rd>, #<const>
```

MVNS variant

Applies when S == 1.

```
MVNS{<c>}{<q>} <Rd>, #<const>
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for all variants of this encoding

```
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-3908.

<q> See *Standard assembler syntax fields* on page F2-3908.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- For the MVNS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* on page F2-3924 for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* on page F2-3923 for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F5.1.124 MVN, MVNS (register)

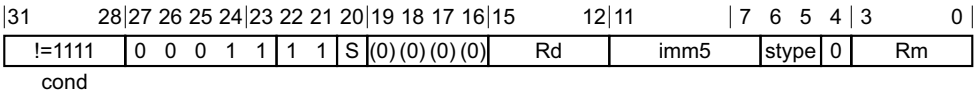
Bitwise NOT (register) writes the bitwise inverse of a register value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-3787.
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-5524.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1



MVN, rotate right with extend variant

Applies when `S == 0 && imm5 == 00000 && stype == 11`.

```
MVN{<c>}{<q>} <Rd>, <Rm>, RRX
```

MVN, shift or rotate by value variant

Applies when `S == 0 && !(imm5 == 00000 && stype == 11)`.

```
MVN{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

MVNS, rotate right with extend variant

Applies when `S == 1 && imm5 == 00000 && stype == 11`.

```
MVNS{<c>}{<q>} <Rd>, <Rm>, RRX
```

MVNS, shift or rotate by value variant

Applies when `S == 1 && !(imm5 == 00000 && stype == 11)`.

```
MVNS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

T1

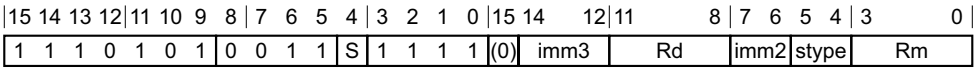
T1 variant

```
MVN<c>{<q>} <Rd>, <Rm> // Inside IT block
MVNS{<q>} <Rd>, <Rm> // Outside IT block
```

Decode for this encoding

```
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

T2



MVN, rotate right with extend variant

Applies when `S == 0 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
MVN{<c>}{<q>} <Rd>, <Rm>, RRX
```

MVN, shift or rotate by value variant

Applies when `S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
MVN<c>.W <Rd>, <Rm> // Inside IT block, and <Rd>, <Rm> can be represented in T1
MVN{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

MVNS, rotate right with extend variant

Applies when `S == 1 && imm3 == 000 && imm2 == 00 && stype == 11`.

```
MVNS{<c>}{<q>} <Rd>, <Rm>, RRX
```

MVNS, shift or rotate by value variant

Applies when `S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11)`.

```
MVNS.W <Rd>, <Rm> // Outside IT block, and <Rd>, <Rm> can be represented in T1
MVNS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```
