G8.3.22 DBGOSLAR, Debug OS Lock Access Register

The DBGOSLAR characteristics are:

Purpose

Provides a lock for the debug registers. The OS Lock also disables some debug exceptions and debug events.

Configurations

AArch32 System register DBGOSLAR[31:0] is architecturally mapped to AArch64 System register OSLAR_EL1[31:0].

AArch32 System register DBGOSLAR[31:0] is architecturally mapped to External register OSLAR_EL1[31:0].

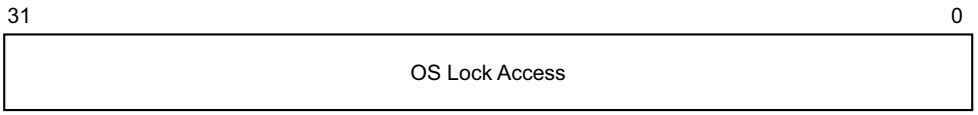
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGOSLAR is a 32-bit register.

Field descriptions

The DBGOSLAR bit assignments are:



OS Lock Access, bits [31:0]

OS Lock Access. Writing the value 0xC5ACCE55 to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.

Use DBGOSLSR.OSLK to check the current status of the lock.

Accessing the DBGOSLAR

Accesses to this register use the following encodings in the System instruction encoding space:

MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1110	0b000	0b0001	0b0000	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && MDCR_EL2.<TDE,TDOSA> != '00' then
        AArch64.AArch32SystemAccessTrap(EL2, 0x05);
    elsif EL2Enabled() && ELUsingAArch32(EL2) && HDCR.<TDE,TDOSA> != '00' then
        AArch32.TakeHypTrapException(0x05);
    elsif HaveEL(EL3) && !ELUsingAArch32(EL3) && MDCR_EL3.TDOSA == '1' then
        AArch64.AArch32SystemAccessTrap(EL3, 0x05);
    else
        DBGOSLAR = R[t];

G8.3.23 DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

Purpose

Provides status information for the OS Lock.

Configurations

AArch32 System register DBGOSLSR[31:0] is architecturally mapped to AArch64 System register OSLSR_EL1[31:0].

The OS Lock status is also visible in the external debug interface through EDPRSR.

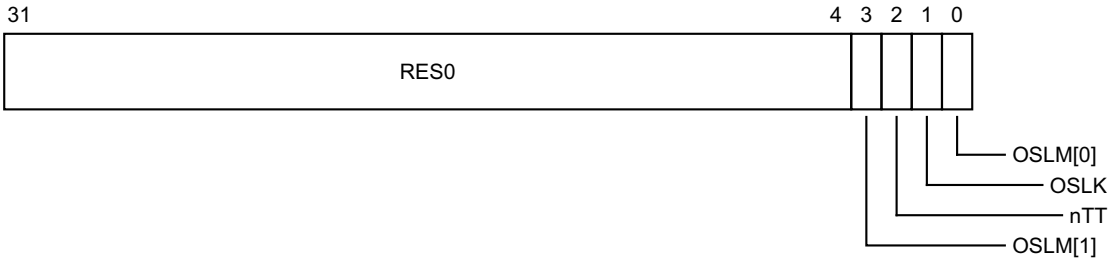
This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGOSLSR is a 32-bit register.

Field descriptions

The DBGOSLSR bit assignments are:



Bits [31:4]

Reserved, RES0.

OSLM[1], bit [3]

This field is bit[1] of OSLM[1:0].

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented.

`0b00` OS Lock not implemented.

`0b10` OS Lock implemented.

All other values are reserved. In an Armv8 implementation the value `0b00` is not permitted.

The OSLM field is split as follows:

- OSLM[1] is DBGOSLSR[3].
- OSLM[0] is DBGOSLSR[0].

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status. The possible values are:

`0b0` OS Lock unlocked.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 OS Lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On a Cold reset, this field resets to 1.

OSLM[0], bit [0]

This field is bit[0] of OSLM[1:0].

See OSLM[1] for the field description.

Accessing the DBGOSLSR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1110	0b000	0b0001	0b0001	0b100

G8.3.24 DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

Configurations

AArch32 System register DBGPRCR[31:0] is architecturally mapped to AArch64 System register DBGPRCR_EL1[31:0].

Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

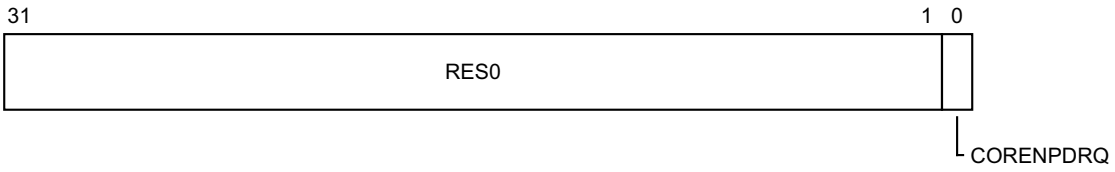
This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGPRCR is a 32-bit register.

Field descriptions

The DBGPRCR bit assignments are:



Bits [31:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

`0b0` If the system responds to a powerdown request, it powers down Core power domain.

`0b1` If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see *Core power domain power states* on page H6-6808.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

G8.3.25 DBGVCR, Debug Vector Catch Register

The DBGVCR characteristics are:

Purpose

Controls Vector Catch debug events.

Configurations

AArch32 System register DBGVCR[31:0] is architecturally mapped to AArch64 System register DBGVCR32_EL2[31:0].

This register is required in all implementations.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

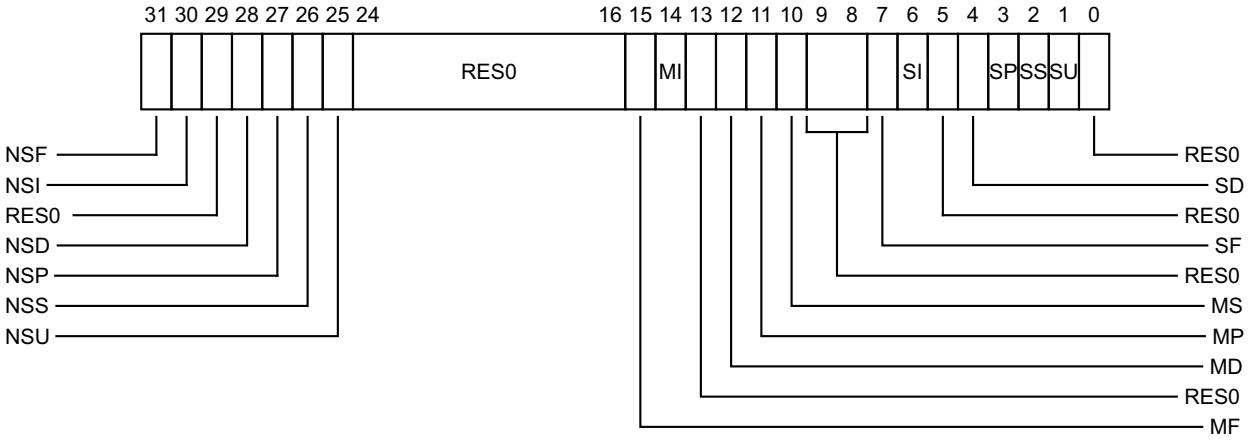
Attributes

DBGVCR is a 32-bit register.

Field descriptions

The DBGVCR bit assignments are:

When HaveEL(EL3) and ELUsingAArch32(EL3):



NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is `0x1C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is `0x18`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is `0x04`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [24:16]

Reserved, RES0.

MF, bit [15]

FIQ vector catch enable in Monitor mode.

The exception vector offset is `0x1C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

MI, bit [14]

IRQ vector catch enable in Monitor mode.

The exception vector offset is `0x18`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

MD, bit [12]

Data Abort vector catch enable in Monitor mode.

The exception vector offset is `0x10`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

MP, bit [11]

Prefetch Abort vector catch enable in Monitor mode.

The exception vector offset is `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

MS, bit [10]

Secure Monitor Call (SMC) vector catch enable in Monitor mode.

The exception vector offset is `0x08`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [9:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The exception vector offset is 0x1C.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is 0x18.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is 0x10.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is 0x0C.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is 0x08.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

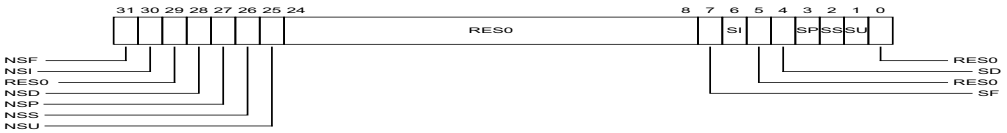
The exception vector offset is 0x04.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

When HaveEL(EL3) and !ELUsingAArch32(EL3):



NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is 0x1C.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is 0x18.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is `0x04`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [24:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is `0x1C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is `0x18`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is `0x10`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is `0x08`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Warm reset, this field resets to an architecturally UNKNOWN value.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

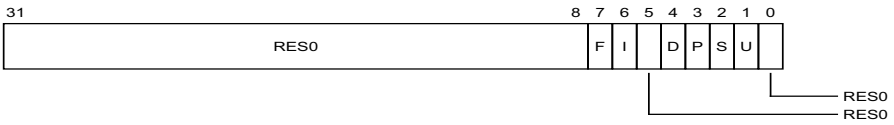
The exception vector offset is `0x04`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

When !HaveEL(EL3):



Bits [31:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.

The exception vector offset is `0x1C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [6]

IRQ vector catch enable.

The exception vector offset is `0x18`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

D, bit [4]

Data Abort vector catch enable.

The exception vector offset is `0x10`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P, bit [3]

Prefetch Abort vector catch enable.

The exception vector offset `0x0C`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

S, bit [2]

Supervisor Call (SVC) vector catch enable.

The exception vector offset is `0x08`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [1]

Undefined Instruction vector catch enable.

The exception vector offset is `0x04`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

G8.3.26 DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n> characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>.

Configurations

AArch32 System register DBGWCR<n>[31:0] is architecturally mapped to AArch64 System register DBGWCR<n>_EL1[31:0].

AArch32 System register DBGWCR<n>[31:0] is architecturally mapped to External register DBGWCR<n>_EL1[31:0].

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

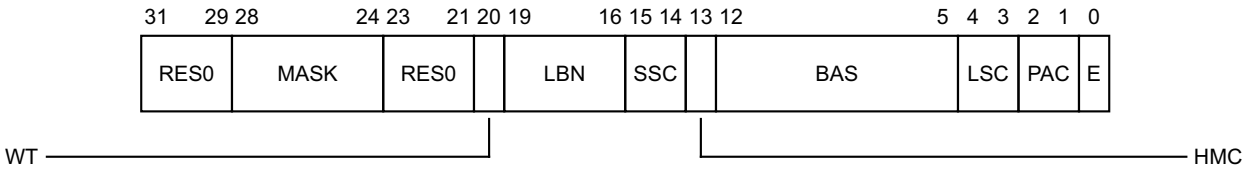
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGWCR<n> is a 32-bit register.

Field descriptions

The DBGWCR<n> bit assignments are:



When the E field is zero, all the other fields in the register are ignored.

Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`0b00000` No mask.

`0b00001` Reserved.

`0b00010` Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from `0b00011` masking 3 address bits (`0x00000007` mask for address) to `0b11111` masking 31 address bits (`0x7FFFFFFF` mask for address).

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [23:21]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

WT, bit [20]

Watchpoint type. Possible values are:

`0b0` Unlinked data address match.

`0b1` Linked data address match.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-5637, and *Reserved DBGBCR<n>.{SSC, HMC, PMC} values* on page G2-5649.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page G2-5655.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n> is being watched.

BAS	Description
`0bxxxxxxx1`	Match byte at DBGWVR<n>
`0bxxxxxx1x`	Match byte at DBGWVR<n>+1
`0bxxxxx1xx`	Match byte at DBGWVR<n>+2
`0bxxxx1xxx`	Match byte at DBGWVR<n>+3

In cases where DBGWVR<n> addresses a double-word:

BAS	Description, if DBGWVR<n>[2] == 0
`0bxxx1xxxx`	Match byte at DBGWVR<n>+4
`0bxx1xxxxx`	Match byte at DBGWVR<n>+5
`0bx1xxxxxx`	Match byte at DBGWVR<n>+6
`0b1xxxxxxx`	Match byte at DBGWVR<n>+7

If DBGWVR<n>[2] == 1, only BAS[3:0] are used and BAS[7:4] are ignored. Arm deprecates setting DBGWVR<n>[2] == 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The valid values for BAS are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See *Reserved DBGWCR<n>.BAS values* on page G2-5663

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

`0b01` Match instructions that load from a watchpointed address.

`0b10` Match instructions that store to a watchpointed address.

`0b11` Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page G2-5655.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint n. Possible values are:

`0b0` Watchpoint disabled.

`0b1` Watchpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGWCR<n>

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.3.27 DBGWFAR, Debug Watchpoint Fault Address Register

The DBGWFAR characteristics are:

Purpose

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RES0.

Configurations

There are no configuration notes.

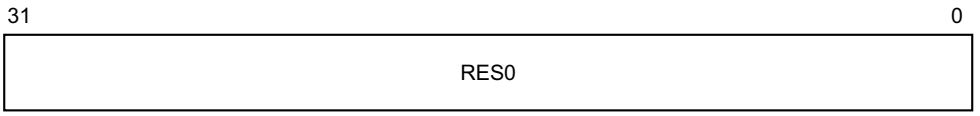
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGWFAR is a 32-bit register.

Field descriptions

The DBGWFAR bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the DBGWFAR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.3.28 DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n> characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>.

Configurations

AArch32 System register DBGWVR<n>[31:0] is architecturally mapped to AArch64 System register DBGWVR<n>_EL1[31:0].

AArch32 System register DBGWVR<n>[31:0] is architecturally mapped to External register DBGWVR<n>_EL1[31:0].

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

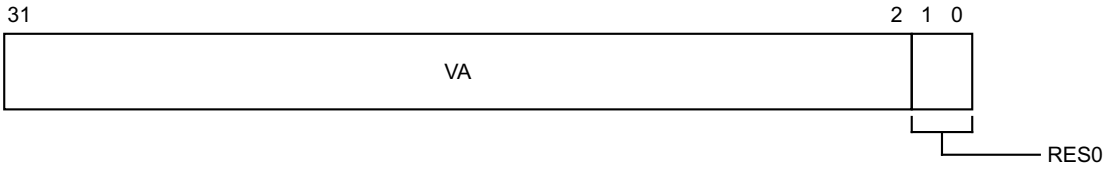
This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values.The register is not affected by a Warm reset.

Attributes

DBGWVR<n> is a 32-bit register.

Field descriptions

The DBGWVR<n> bit assignments are:



VA, bits [31:2]

Bits[31:2] of the address value for comparison.

Arm deprecates setting DBGWVR<n>[2] == 1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.3.29 DLR, Debug Link Register

The DLR characteristics are:

Purpose

In Debug state, holds the address to restart from.

Configurations

AArch32 System register DLR[31:0] is architecturally mapped to AArch64 System register DLR_EL0[31:0].

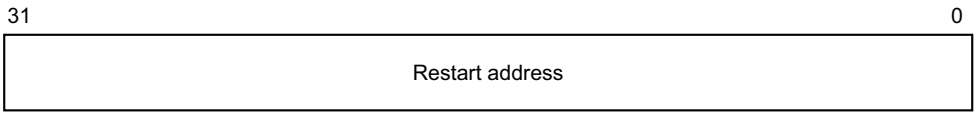
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DLR is a 32-bit register.

Field descriptions

The DLR bit assignments are:



Bits [31:0]

Restart address.

Accessing the DLR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b011	0b0100	0b0101	0b001

G8.3.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

Purpose

Holds the saved process state for Debug state. On entering Debug state, PSTATE information is written to this register. On exiting Debug state, values are copied from this register to PSTATE.

Configurations

AArch32 System register DSPSR[31:0] is architecturally mapped to AArch64 System register DSPSR_EL0[31:0].

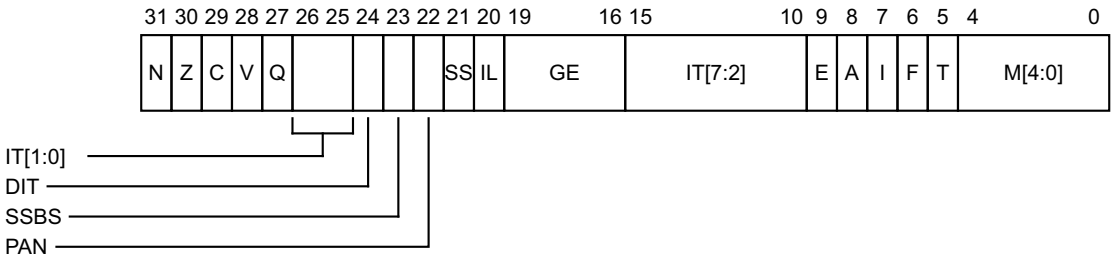
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DSPSR is a 32-bit register.

Field descriptions

The DSPSR bit assignments are:



N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on entering Debug state, and copied to PSTATE.N on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on entering Debug state, and copied to PSTATE.Z on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on entering Debug state, and copied to PSTATE.C on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on entering Debug state, and copied to PSTATE.V on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Q, bit [27]

Overflow or saturation flag. Set to the value of PSTATE.Q on entering Debug state, and copied to PSTATE.Q on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IT[1:0], bits [26:25]

If-Then. Set to the value of PSTATE.IT[1:0] on entering Debug state, and copied to PSTATE.IT[1:0] on exiting Debug state.

On exiting Debug state DSPSR.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

DIT, bit [24]

When ARMv8.4-DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSBS, bit [23]

When ARMv8.0-SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on entering Debug state, and copied to PSTATE.SSBS on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When ARMv8.1-PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on entering Debug state, and conditionally copied to PSTATE.SS on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on entering Debug state, and copied to PSTATE.IL on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

GE, bits [19:16]

Greater than or Equal flags. Set to the value of PSTATE.GE on entering Debug state, and copied to PSTATE.GE on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

IT[7:2], bits [15:10]

If-Then. Set to the value of PSTATE.IT[7:2] on entering Debug state, and copied to PSTATE.IT[7:2] on exiting Debug state.

DSPSR.IT must contain a value that is valid for the instruction being returned to.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E, bit [9]

Endianness. Set to the value of PSTATE.E on entering Debug state, and copied to PSTATE.E on exiting Debug state.

If the implementation does not support big-endian operation, DSPSR.E is RES0. If the implementation does not support little-endian operation, DSPSR.E is RES1. On exiting Debug state, if the implementation does not support big-endian operation at the Exception level being returned to, DSPSR.E is RES0, and if the implementation does not support little-endian operation at the Exception level being returned to, DSPSR.E is RES1.

This field resets to an architecturally UNKNOWN value.

A, bit [8]

SError interrupt mask. Set to the value of PSTATE.A on entering Debug state, and copied to PSTATE.A on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on entering Debug state, and copied to PSTATE.I on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on entering Debug state, and copied to PSTATE.F on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

T, bit [5]

T32 Instruction set state. Set to the value of PSTATE.T on entering Debug state, and copied to PSTATE.T on exiting Debug state.

This field resets to an architecturally UNKNOWN value.

M[4:0], bits [4:0]

Mode. Set to the value of PSTATE.M[4:0] on entering Debug state, and copied to PSTATE.M[4:0] on exiting Debug state.

`0b10000` User.

`0b10001` FIQ.

`0b10010` IRQ.

`0b10011` Supervisor.

`0b10110` Monitor.

`0b10111` Abort.

`0b11010` Hyp.

`0b11011` Undefined.

`0b11111` System.

Other values are reserved. If DSPSR.M[4:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in *Illegal return events from AArch32 state* on page G1-5524.

This field resets to an architecturally UNKNOWN value.

Accessing the DSPSR

Accesses to this register use the following encodings in the System instruction encoding space:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

G8.3.31 HDCR, Hyp Debug Control Register

The HDCR characteristics are:

Purpose

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors Extension.

Configurations

AArch32 System register HDCR[31:0] is architecturally mapped to AArch64 System register MDCR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3, and other than for a direct read of the register, the PE behaves as if HDCR.HPMN == PMCR.N.

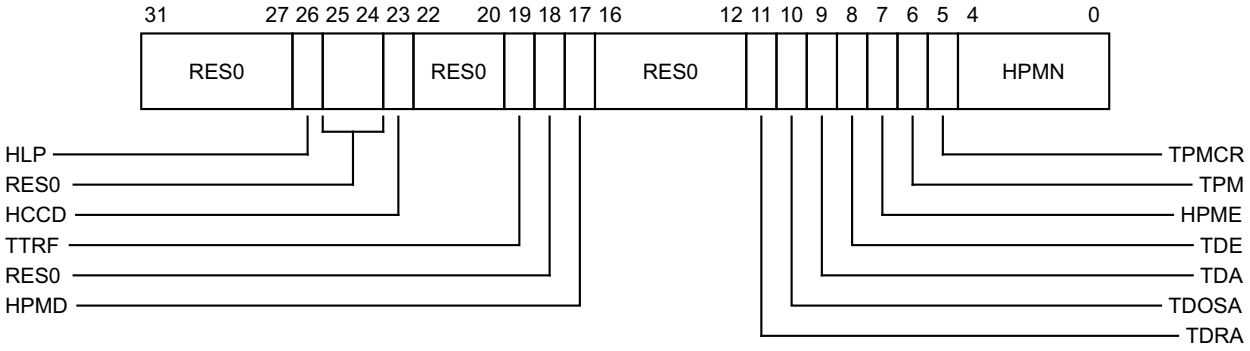
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HDCR is a 32-bit register.

Field descriptions

The HDCR bit assignments are:



Bits [31:27]

Reserved, RES0.

HLP, bit [26]

When ARMv8.5-PMU is implemented:

Hypervisor Long event counter enable. Determines when unsigned overflow is recorded by a counter overflow bit.

`0b0` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>[31:0].

`0b1` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>[63:0].

If the highest implemented Exception level is using AArch32, it is IMPLEMENTATION DEFINED whether this bit is read/write or RAZ/WI.

If HDCR.HPMN is less than PMCR.N, this bit affects the operation of event counters in the range [HDCR.HPMN..(PMCR.N-1)]. Otherwise this bit has no effect on the operation of the event counters.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The effect of HDCR.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state.

For more information see the description of the HDCR.HPMN field.

Note

PMEVCNTR<n>[63:32] cannot be accessed directly in AArch32 state.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

Bits [25:24]

Reserved, RES0.

HCCD, bit [23]

When ARMv8.5-PMU is implemented:

Hypervisor Cycle Counter Disable. Prohibits PMCCNTR from counting at EL2.

`0b0` Cycle counting by PMCCNTR is not affected by this bit.

`0b1` Cycle counting by PMCCNTR is prohibited at EL2.

This bit does not affect the CPU_CYCLES event or any other event that counts cycles.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

Bits [22:20]

Reserved, RES0.

TTRF, bit [19]

When ARMv8.4-Trace is implemented:

Traps use of the Trace Filter Control registers at EL1 to EL2.

`0b0` Accesses to TRFCR at EL1 are not affected by this control bit.

`0b1` Accesses to TRFCR at EL1 generate a Hyp Trap exception.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

Bit [18]

Reserved, RES0.

HPMD, bit [17]

When ARMv8.1-PMU is implemented:

Guest Performance Monitors Disable. This control prohibits event counting at EL2.

`0b0` Event counting allowed in Hyp mode.

`0b1` Event counting prohibited in Hyp mode.

If ARMv8.2-Debug is not implemented, event counting is prohibited unless enabled by the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This control applies only to:

- The event counters in the range [0..(HDCR.HPMN-1)].
- If PMCR.DP is set to 1, PMCCNTR.

The other event counters are unaffected. When PMCR.DP is set to 0, PMCCNTR is unaffected.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

Bits [16:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode.

`0b0` This control does not cause any instructions to be trapped.

`0b1` Non-secure EL0 and EL1 System register accesses to the DBGDRAR or DBGDSAR are trapped to Hyp mode, unless it is trapped by DBGDSCRext.UDCCdis.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

TDOSA, bit [10]

When ARMv8.0-DoubleLock is implemented:

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

`0b0` This control does not cause any instructions to be trapped.

`0b1` Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- DBGOSLSR, DBGOSLAR, DBGOSDLR, and DBGPRCR.
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

Note

These registers are not accessible at EL0.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Otherwise:

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

`0b0` This control does not cause any instructions to be trapped.

`0b1` Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- DBGOSLSR, DBGOSLAR, and DBGPRCR.
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

It is IMPLEMENTATION DEFINED whether accesses to DBGOSDLR are trapped.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

These registers are not accessible at EL0.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

TDA, bit [9]

Trap debug access. Traps Non-secure EL0 and EL1 System register accesses to those debug System registers in the (coproc==`0b1110`) encoding space that are not trapped by either of the following:

- HDCR.TDRA.
- HDCR.TDOSA.

`0b0` This control does not cause any instructions to be trapped.

`0b1` Non-secure EL0 or EL1 System register accesses to the debug registers, other than the registers trapped by HDCR.TDRA and HDCR.TDOSA, are trapped to Hyp mode, unless it is trapped by DBGDSCRext.UDCCdis.

Traps of AArch32 accesses to DBGDTRRXint and DBGDTRTXint are ignored in Debug state.

If HCR.TGE or HDCR.TDE is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

`0b0` This control has no effect on the routing of debug exceptions, and has no effect on Non-secure accesses to debug registers.

`0b1` Debug exceptions generated at EL1 or EL0 are routed to EL2 when enabled in the current Security state. The HDCR.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

When HCR.TGE == 1, the PE behaves as if the value of this field is 1 for all purposes other than returning the value of a direct read of the register.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

HPME, bit [7]

When PMUv3 is implemented:

[HDCR.HPMN..(N-1)] event counters enable.

`0b0` Event counters in the range [HDCR.HPMN..(PMCR.N-1)] are disabled.

`0b1` Event counters in the range [HDCR.HPMN..(PMCR.N-1)] are enabled by PMCNTENSET.

If HDCR.HPMN is less than PMCR.N, the event counters in the range [HDCR.HPMN..(PMCR.N-1)], are enabled and disabled by this bit. Otherwise this bit has no effect on the operation of the event counters.

Note

The effect of HDCR.HPMN on the operation of this bit applies regardless of whether EL2 is enabled in the current Security state.

For more information see the description of the HPMN field.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TPM, bit [6]

When PMUv3 is implemented:

Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to Hyp mode.

`0b0` This control does not cause any instructions to be trapped.

`0b1` Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

TPMCR, bit [5]

When PMUv3 is implemented:

Trap PMCR accesses. Traps Non-secure EL0 and EL1 accesses to the PMCR to Hyp mode.

`0b0` This control does not cause any instructions to be trapped.

`0b1` Non-secure EL0 and EL1 accesses to the PMCR are trapped to Hyp mode, unless it is trapped by PMUSERENR.EN.

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

HPMN, bits [4:0]

When PMUv3 is implemented:

Defines the number of event counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If HPMN is less than PMCR.N, HPMN divides the event counters into two ranges, [0..(HPMN-1)] and [HPMN..(PMCR.N-1)].

For an event counter in the range [0..(HPMN-1)]:

- The counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the counters is enabled.
- If ARMv8.5-PMU is implemented, PMCR.LP determines whether the counter overflows at PMEVCNTR<n>[31:0] or PMEVCNTR<n>[63:0].
- PMCR.E enables the operation of counters in this range.

Note

If HPMN is equal to PMCR.N, this applies to all event counters.

If HPMN is less than PMCR.N, for an event counter in the range [HPMN..(PMCR.N-1)]:

- The counter is accessible only from EL2 and from Secure state.
- If ARMv8.5-PMU is implemented, HDCR.HLP determines whether the counter overflows at PMEVCNTR<n>[31:0] or PMEVCNTR<n>[63:0].

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- HDCR.HPME enables the operation of counters in this range.

If this field is set to 0, or to a value larger than PMCR.N, then the following CONSTRAINED UNPREDICTABLE behaviors apply:

- The value returned by a direct read of HDCR.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an UNKNOWN non-zero value less than or equal to PMCR.N.
  - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to the value in PMCR.N.

Otherwise:

Reserved, RES0.

Accessing the HDCR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.3.32 HTRFCR, Hyp Trace Filter Control Register

The HTRFCR characteristics are:

Purpose

Provides EL2 controls for Trace.

Configurations

AArch32 System register HTRFCR[31:0] is architecturally mapped to AArch64 System register TRFCR_EL2[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to HTRFCR are UNDEFINED.

If EL2 is not implemented, this register is RES0 from Monitor mode when SCR.NS == 1.

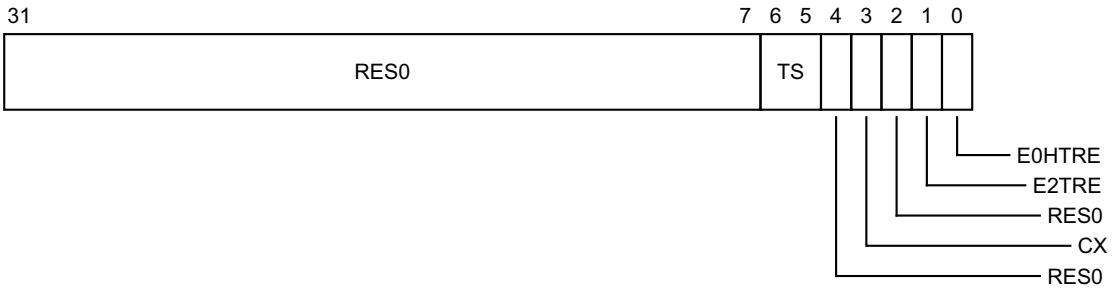
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HTRFCR is a 32-bit register.

Field descriptions

The HTRFCR bit assignments are:



Bits [31:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

`0b00` The timestamp is controlled by TRFCR.TS.

`0b01` Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF.

`0b11` Physical timestamp. The traced timestamp is the physical counter value.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to `0`.

Bit [4]

Reserved, RES0.

CX, bit [3]

VMID Trace Enable.

`0b0` VMID tracing is not allowed.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 VMID tracing is allowed.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

Bit [2]

Reserved, RES0.

E2TRE, bit [1]

EL2 Trace Enable.

0b0 Tracing is prohibited at EL2.

0b1 Tracing is allowed at EL2.

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

E0HTRE, bit [0]

EL0 Trace Enable.

0b0 Tracing is prohibited at EL0 when HCR.TGE == 1.

0b1 Tracing is allowed at EL0 when HCR.TGE == 1.

This field is ignored if any of the following are true:

- The PE is in Secure state.
- SelfHostedTraceEnabled() == FALSE.
- HCR.TGE == 0.

On a Warm reset, in a system where the PE resets into EL2 or EL3, this field resets to 0.

Accessing the HTRFCR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b100	0b0001	0b0010	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;

G8.3.33 PMMIR, Performance Monitors Machine Identification Register

The PMMIR characteristics are:

Purpose

Describes Performance Monitors parameters specific to the implementation to software.

Configurations

This register is present only when ARMv8.4-PMU is implemented. Otherwise, direct accesses to PMMIR are UNDEFINED.

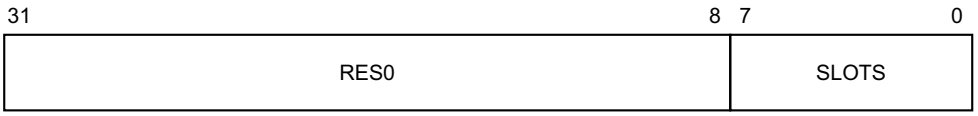
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMMIR is a 32-bit register.

Field descriptions

The PMMIR bit assignments are:



Bits [31:8]

Reserved, RES0.

SLOTS, bits [7:0]

Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL_SLOT event is not implemented, this field might read as zero.

Accessing the PMMIR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1001	0b1110	0b110

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if EL2Enabled() && !ELUsingAArch32(EL2) && HSTR_EL2.T9 == '1' then
        AArch64.AArch32SystemAccessTrap(EL2, 0x03);
    elsif EL2Enabled() && ELUsingAArch32(EL2) && HSTR.T9 == '1' then

G8.3.34 SDCR, Secure Debug Control Register

The SDCR characteristics are:

Purpose

Provides EL3 configuration options for self-hosted debug, trace, and the Performance Monitors Extension.

Configurations

AArch32 System register SDCR[31:0] can be mapped to AArch64 System register MDCR_EL3[31:0], but this is not architecturally mandated.

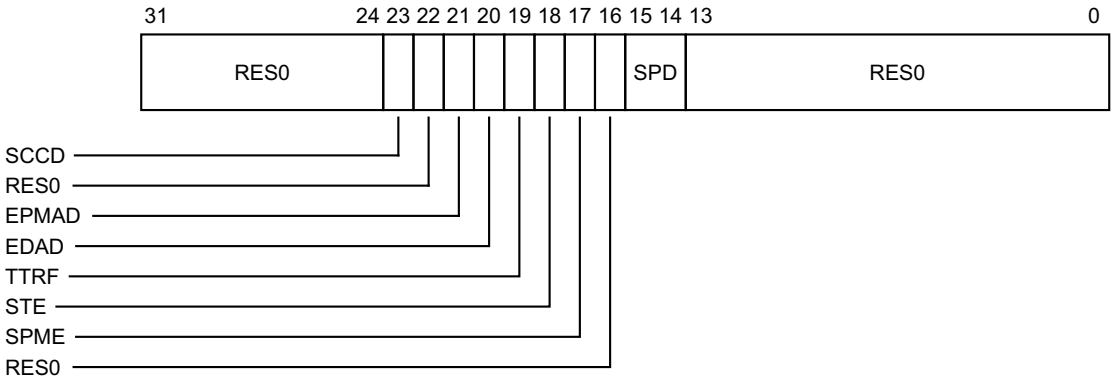
Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

Attributes

SDCR is a 32-bit register.

Field descriptions

The SDCR bit assignments are:



Bits [31:24]

Reserved, RES0.

SCCD, bit [23]

When ARMv8.5-PMU is implemented:

Secure Cycle Counter Disable. Prohibits PMCCNTR from counting in Secure state.

`0b0` Cycle counting by PMCCNTR is not affected by this bit.

`0b1` Cycle counting by PMCCNTR is prohibited in Secure state.

This bit does not affect the CPU_CYCLES event or any other event that counts cycles.

In a system where the PE resets into EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

Bit [22]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EPMAD, bit [21]

When ARMv8.4-Debug is implemented and PMUv3 is implemented:

External Performance Monitors Non-secure access disable. Controls Non-secure access to Performance Monitors registers by an external debugger.

`0b0` Non-secure access to the Performance Monitors registers from an external debugger is permitted.

`0b1` Non-secure access to the Performance Monitors registers from an external debugger is not permitted.

If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.

Otherwise, if EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this field is `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

When PMUv3 is implemented:

External Performance Monitors access disable. Controls access to Performance Monitors registers by an external debugger.

`0b0` Access to Performance Monitors registers from an external debugger is permitted.

`0b1` Access to Performance Monitors registers from an external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors Extension does not support external debug interface accesses this bit is RES0.

Otherwise, if EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this field is `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

EDAD, bit [20]

When ARMv8.4-Debug is implemented:

External debug Non-secure access disable. Controls Non-secure access to breakpoint, watchpoint, and OSLAR_EL1 registers by an external debugger.

`0b0` Non-secure access to debug registers from an external debugger is permitted.

`0b1` Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 from an external debugger is not permitted.

If EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this field is `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

When ARMv8.2-Debug is implemented:

External debug access disable. Controls access to breakpoint, watchpoint, and OSLAR_EL1 registers by an external debugger.

`0b0` Access to debug registers from an external debugger is permitted.

`0b1` Access to breakpoint registers, watchpoint registers and OSLAR_EL1 from an external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this field is `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

External debug access disable. Controls access to breakpoint, watchpoint, and optionally OSLAR_EL1 registers by an external debugger.

`0b0` Access to debug registers from an external debugger is permitted.

`0b1` Access to breakpoint registers and watchpoint registers from an external debugger is not permitted, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

It is IMPLEMENTATION DEFINED whether access to the OSLAR_EL1 register from an external debugger is permitted or not permitted.

If EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this field is `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

TTRF, bit [19]

When ARMv8.4-Trace is implemented:

Trap Trace Filter controls. Controls whether accesses at EL2 and EL1 to the trace filter control registers are trapped to EL3.

`0b0` Accesses to HTRFCR and TRFCR registers are not affected by this control bit.

`0b1` When not in Monitor mode, accesses to HTRFCR and TRFCR registers generate a Monitor Trap exception, unless the access generates a higher priority exception.

In a system where the PE resets into EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

STE, bit [18]

When ARMv8.4-Trace is implemented:

Secure Trace Enable. This bit enables tracing in Secure state and controls the level of authentication required by an external debugger to enable external tracing.

`0b0` Trace is prohibited in Secure state unless overridden by the IMPLEMENTATION DEFINED authentication interface.

`0b1` Trace in Secure state is not affected by this bit.

This bit also controls the level of authentication required by an external debugger to enable external tracing. See *Register controls to enable self-hosted trace* on page G3-5678.

If EL3 is not implemented and the Effective value of SCR.NS is `0b0`, the PE behaves as if this bit is set to `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

SPME, bit [17]

When ARMv8.2-Debug is implemented and PMUv3 is implemented:

Secure Performance Monitors enable. This allows event counting in Secure state.

`0b0` Event counting prohibited in Secure state.

`0b1` Event counting allowed in Secure state.

If EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this bit is `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When PMUv3 is implemented:

Secure Performance Monitors enable. This allows event counting in Secure state.

`0b0` Event counting prohibited in Secure state, unless ExternalSecureNoninvasiveDebugEnabled() is TRUE.

`0b1` Event counting allowed in Secure state.

If EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this bit is `0b1`.

In a system where the PE resets into EL3, this field resets to `0`.

Otherwise:

Reserved, RES0.

Bit [16]

Reserved, RES0.

SPD, bits [15:14]

AArch32 Secure self-hosted Privileged Debug. Enables or disables debug exceptions from EL3, other than Breakpoint Instruction exceptions

`0b00` Legacy mode. Debug exceptions from EL3 are enabled by the authentication interface.

`0b10` Secure privileged debug disabled. Debug exceptions from EL3 are disabled.

`0b11` Secure privileged debug enabled. Debug exceptions from EL3 are enabled.

Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as `0b00`. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field has no effect on Breakpoint Instruction exceptions. These are always enabled.

This field is ignored in Non-secure state.

If debug exceptions from EL3 are enabled, then debug exceptions from Secure EL0 are also enabled.

Otherwise, debug exceptions from Secure EL0 are enabled only if the value of SDER.SUIDEN is `0b1`.

If EL3 is not implemented and the Effective value of SCR.NS is `0b0`, then the Effective value of this field is `0b11`.

In a system where the PE resets into EL3, this field resets to `0`.

Bits [13:0]

Reserved, RES0.

Accessing the SDCR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.3.35 SDER, Secure Debug Enable Register

The SDER characteristics are:

Purpose

Controls invasive and non-invasive debug in the Secure EL0 mode.

Configurations

AArch32 System register SDER[31:0] is architecturally mapped to AArch64 System register SDER32_EL3[31:0].

This register is present only when HaveEL(EL3) or the implemented Security state is Secure state. Otherwise, direct accesses to SDER are UNDEFINED.

This register is ignored by the PE when one or more of the following are true:

- The PE is in Non-secure state.
- EL1 is using AArch64.

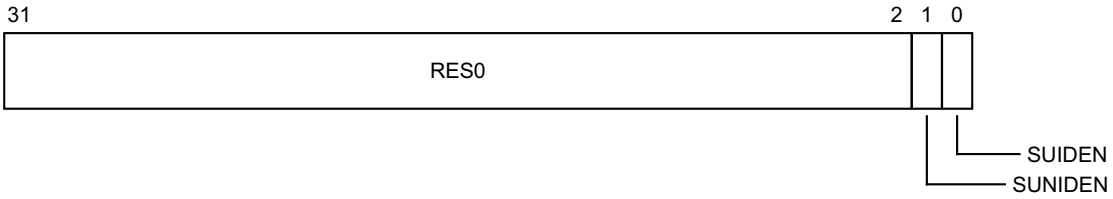
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SDER is a 32-bit register.

Field descriptions

The SDER bit assignments are:



Bits [31:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable.

`0b0` This bit does not affect Performance Monitors event counting at Secure EL0

`0b1` If EL3 or EL1 is using AArch32, Performance Monitors event counting is allowed in Secure EL0.

On a Warm reset, this field resets to `0`.

SUIDEN, bit [0]

Secure User Invasive Debug Enable.

`0b0` This bit does not affect the generation of debug exceptions at Secure EL0.

`0b1` If EL3 or EL1 is using AArch32, debug exceptions from Secure EL0 are enabled.

On a Warm reset, this field resets to `0`.

G8.3.36 TRFCR, Trace Filter Control Register

The TRFCR characteristics are:

Purpose

Provides EL1 controls for Trace.

Configurations

AArch32 System register TRFCR[31:0] is architecturally mapped to AArch64 System register TRFCR_EL1[31:0].

This register is present only when ARMv8.4-Trace is implemented. Otherwise, direct accesses to TRFCR are UNDEFINED.

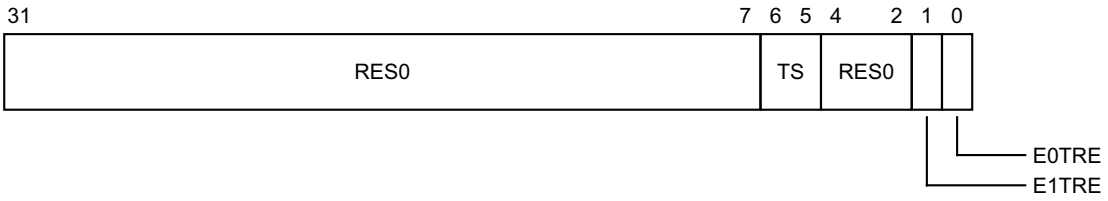
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TRFCR is a 32-bit register.

Field descriptions

The TRFCR bit assignments are:



Bits [31:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

`0b01` Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF.

`0b11` Physical timestamp. The traced timestamp is the physical counter value.

All other values are reserved.

This field is ignored if any of the following are true:

- SelfHostedTraceEnabled() == FALSE.
- HTRFCR.TS is not `0b00`.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [4:2]

Reserved, RES0.

E1TRE, bit [1]

EL1 Trace Enable.

`0b0` Tracing is prohibited in PL1 modes.

`0b1` Tracing is allowed in PL1 modes.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When SelfHostedTraceEnabled() == FALSE, this field is ignored.

On a Warm reset, this field resets to 0.

E0TRE, bit [0]

EL0 Trace Enable.

0b0 Tracing is prohibited at EL0.

0b1 Tracing is allowed at EL0.

This field is ignored if any of the following are true:

- SelfHostedTraceEnabled() == FALSE.
- EL2 is implemented and enabled in the current security state and HCR.TGE == 1.

On a Warm reset, this field resets to 0.

Accessing the TRFCR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.4.1 PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR, increments.

Configurations

AArch32 System register PMCCFILTR[31:0] is architecturally mapped to AArch64 System register PMCCFILTR_EL0[31:0].

AArch32 System register PMCCFILTR[31:0] is architecturally mapped to External register PMCCFILTR_EL0[31:0].

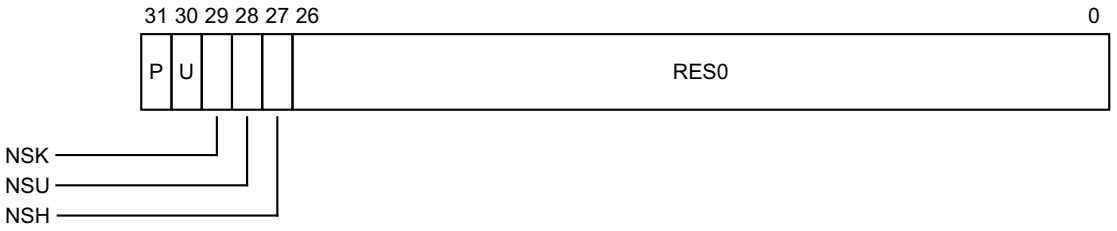
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCFILTR is a 32-bit register.

Field descriptions

The PMCCFILTR bit assignments are:



P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0b0` Count cycles in EL1.

`0b1` Do not count cycles in EL1.

On a Warm reset, this field resets to `0`.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0b0` Count cycles in EL0.

`0b1` Do not count cycles in EL0.

On a Warm reset, this field resets to `0`.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

On a Warm reset, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

On a Warm reset, this field resets to `0`.

NSH, bit [27]

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0b0` Do not count cycles in EL2.

`0b1` Count cycles in EL2.

On a Warm reset, this field resets to `0`.

Bits [26:0]

Reserved, RES0.

Accessing the PMCCFILTR

PMCCFILTR can also be accessed by using PMXEVTYPER with PMSELR.SEL set to `0b11111`.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1110	0b1111	0b111

G8.4.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D7-2671 for more information.

PMCCFILTR determines the modes and states in which the PMCCNTR can increment.

Configurations

AArch32 System register PMCCNTR[63:0] is architecturally mapped to AArch64 System register PMCCNTR_EL0[63:0].

AArch32 System register PMCCNTR[63:0] is architecturally mapped to External register PMCCNTR_EL0[63:0].

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

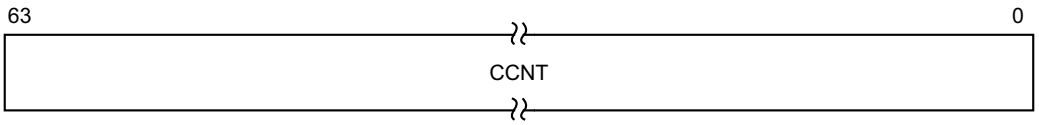
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCNTR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The PMCCNTR bit assignments are:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR.C sets this field to 0.

This field resets to an architecturally UNKNOWN value.

Accessing the PMCCNTR

Accesses to this register use the following encodings in the System instruction encoding space:

G8.4.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range `0x0000` to `0x001F`

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D7-2693.

Configurations

AArch32 System register PMCEID0[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[31:0].

AArch32 System register PMCEID0[31:0] is architecturally mapped to External register PMCEID0[31:0].

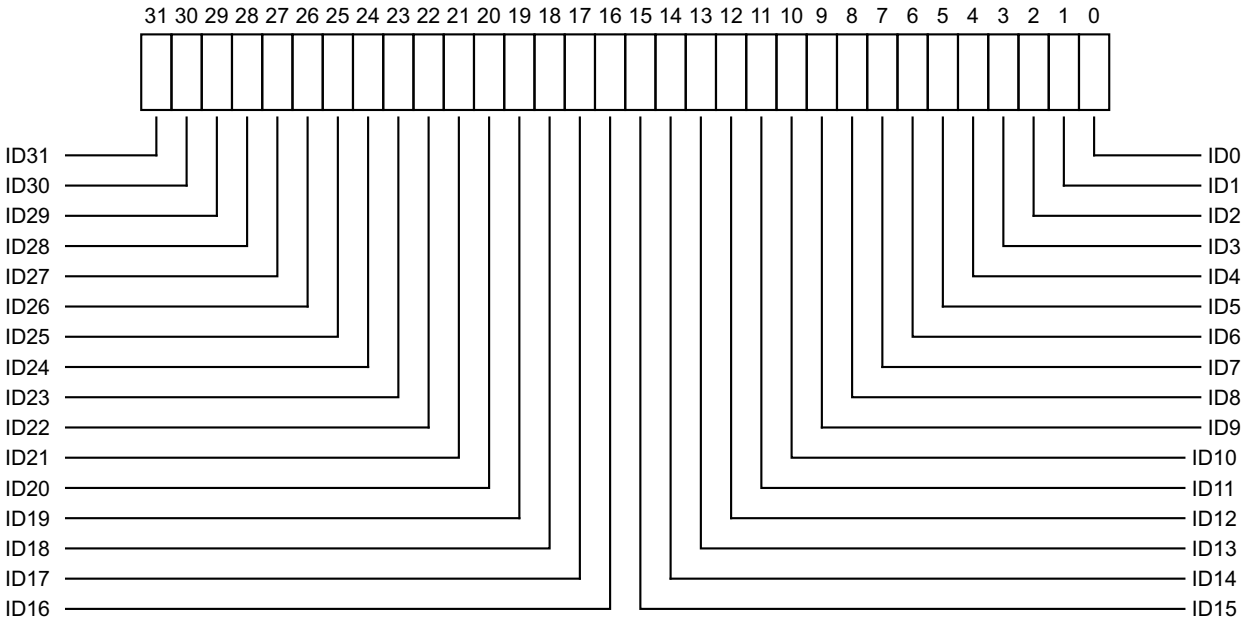
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCEID0 is a 32-bit register.

Field descriptions

The PMCEID0 bit assignments are:



ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event n.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing the PMCEID0

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1001	0b1100	0b110

```

G8.4.4 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range `0x0020` to `0x003F`.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D7-2693.

Configurations

AArch32 System register PMCEID1[31:0] is architecturally mapped to AArch64 System register PMCEID1_EL0[31:0].

AArch32 System register PMCEID1[31:0] is architecturally mapped to External register PMCEID1[31:0].

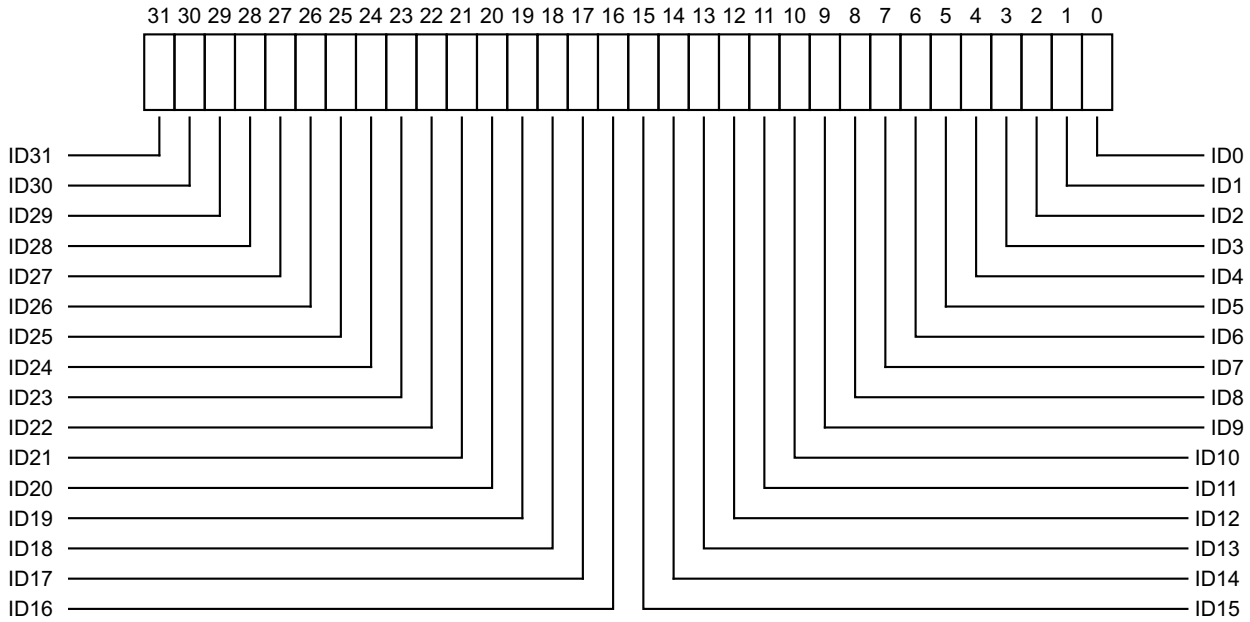
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCEID1 is a 32-bit register.

Field descriptions

The PMCEID1 bit assignments are:



ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event (`0x0020` + n).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For each bit:

`0b0` The common event is not implemented, or not counted.

`0b1` The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing the PMCEID1

Accesses to this register use the following encodings in the System instruction encoding space:

G8.4.5 PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range `0x4000` to `0x401F`.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D7-2693.

Configurations

AArch32 System register PMCEID2[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[63:32].

AArch32 System register PMCEID2[31:0] is architecturally mapped to External register PMCEID2[63:32].

This register is present only when ARMv8.1-PMU is implemented. Otherwise, direct accesses to PMCEID2 are UNDEFINED.

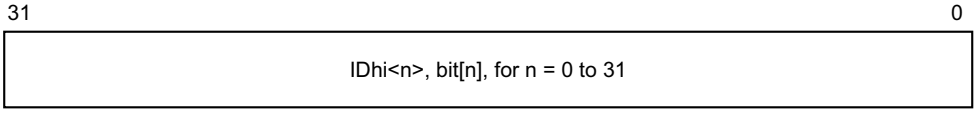
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCEID2 is a 32-bit register.

Field descriptions

The PMCEID2 bit assignments are:



IDhi<n>, bit [n], for n = 0 to 31

IDhi[n] corresponds to common event (`0x4000` + n).

For each bit:

`0b0` The common event is not implemented, or not counted.

`0b1` The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

G8.4.7 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

PMCNTENCLR is used in conjunction with the PMCNTENSET register.

Configurations

AArch32 System register PMCNTENCLR[31:0] is architecturally mapped to AArch64 System register PMCNTENCLR_EL0[31:0].

AArch32 System register PMCNTENCLR[31:0] is architecturally mapped to External register PMCNTENCLR_EL0[31:0].

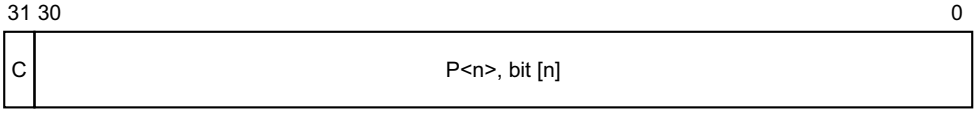
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENCLR is a 32-bit register.

Field descriptions

The PMCNTENCLR bit assignments are:



C, bit [31]

PMCCNTR disable bit. Disables the cycle counter register. Possible values are:

`0b0` When read, means the cycle counter is disabled. When written, has no effect.

`0b1` When read, means the cycle counter is enabled. When written, disables the cycle counter.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter disable bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

`0b0` When read, means that PMEVCNTR<n> is disabled. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n> is enabled. When written, disables PMEVCNTR<n>.

This field resets to an architecturally UNKNOWN value.

Accessing the PMCNTENCLR

G8.4.8 PMCNTENSET, Performance Monitors Count Enable Set register

The PMCNTENSET characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

PMCNTENSET is used in conjunction with the PMCNTENCLR register.

Configurations

AArch32 System register PMCNTENSET[31:0] is architecturally mapped to AArch64 System register PMCNTENSET_EL0[31:0].

AArch32 System register PMCNTENSET[31:0] is architecturally mapped to External register PMCNTENSET_EL0[31:0].

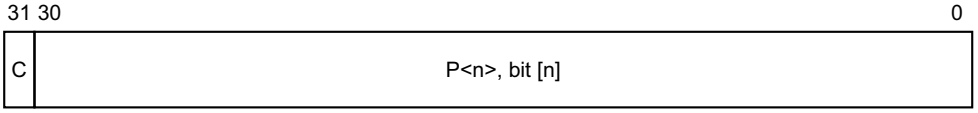
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENSET is a 32-bit register.

Field descriptions

The PMCNTENSET bit assignments are:



C, bit [31]

PMCCNTR enable bit. Enables the cycle counter register. Possible values are:

`0b0` When read, means the cycle counter is disabled. When written, has no effect.

`0b1` When read, means the cycle counter is enabled. When written, enables the cycle counter.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter enable bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

`0b0` When read, means that PMEVCNTR<n> is disabled. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n> event counter is enabled. When written, enables PMEVCNTR<n>.

This field resets to an architecturally UNKNOWN value.

Accessing the PMCNTENSET

G8.4.9 PMCR, Performance Monitors Control Register

The PMCR characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Configurations

AArch32 System register PMCR[31:0] is architecturally mapped to AArch64 System register PMCR_EL0[31:0].

AArch32 System register PMCR[7:0] is architecturally mapped to External register PMCR_EL0[7:0].

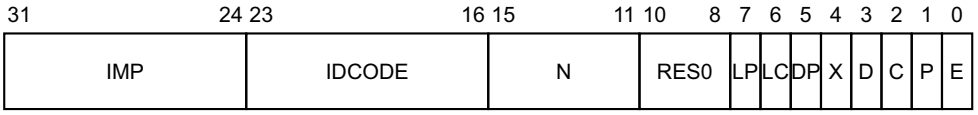
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCR is a 32-bit register.

Field descriptions

The PMCR bit assignments are:



IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

If this field is zero, then PMCR.IDCODE is RES0 and software must use MIDR to identify the PE.

Otherwise this field and PMCR.IDCODE identify the PMU implementation to software. The implementer codes are allocated by Arm. A non-zero value has the same interpretation as MIDR.Implementer.

IDCODE, bits [23:16]

When PMCR.IMP != 0x00:

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that are specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

Otherwise:

Reserved, RES0.

N, bits [15:11]

An RO field that indicates the number of event counters implemented. This value is in the range of `0b00000`-`0b111111`. If the value is `0b00000` then only PMCCNTR_EL0 is implemented. If the value is `0b111111` PMCCNTR_EL0 and 31 event counters are implemented.

In an implementation that includes EL2:

- If EL2 is using AArch32, reads of this field from Non-secure EL1 and Non-secure EL0 return the value of HDCR.HPMN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If EL2 is using AArch64 and enabled in the current Security state, reads of this field from EL1 and EL0 return the value of MDCR_EL2.HPMN.

Access to this field is RO.

Bits [10:8]

Reserved, RES0.

LP, bit [7]

When ARMv8.5-PMU is implemented:

Long event counter enable. Determines when unsigned overflow is recorded by a counter overflow bit.

`0b0` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>[31:0].

`0b1` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>[63:0].

If the highest implemented Exception level is using AArch32, it is IMPLEMENTATION DEFINED whether this bit is read/write or RAZ/WI.

If EL2 is implemented and HDCR.HPMN or MDCR_EL2.HPMN is less than PMCR.N, this bit does not affect the operation of event counters in the range [HDCR.HPMN..(PMCR.N-1)] or [MDCR_EL2.HPMN..(PMCR.N-1)].

PMEVCNTR<n>[63:32] cannot be accessed directly in AArch32 state.

Note

The effect of HDCR.HPMN or MDCR_EL2.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state. For more information, see the description of HDCR.HPMN or MDCR_EL2.HPMN.

On a Warm reset, this field resets to `0`.

Otherwise:

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines when unsigned overflow is recorded by the cycle counter overflow bit.

`0b0` Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR[31:0].

`0b1` Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR[63:0].

Arm deprecates use of PMCR.LC = 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

`0b0` Cycle counting by PMCCNTR is not affected by this bit.

`0b1` When event counting for counters in the range [0..(HDCR.HPMN-1)] or [0..(MDCR_EL2.HPMN-1)] is prohibited, cycle counting by PMCCNTR is disabled.

For more information about the interaction between the Performance Monitors and EL3, see *Effect of EL3 and EL2* on page D7-2679

When EL3 is not implemented, this field is RES0:

- When ARMv8.1-PMU is not implemented.
- When ARMv8.1-PMU is implemented, only if EL2 is not implemented.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise this field is RW.

On a Warm reset, this field resets to `0`.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

`0b0` Do not export events.

`0b1` Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL PE trace unit. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

On a Warm reset, this field resets to `0`.

D, bit [3]

Clock divider. The possible values of this bit are:

`0b0` When enabled, PMCCNTR counts every clock cycle.

`0b1` When enabled, PMCCNTR counts once every 64 clock cycles.

This bit is RW.

If PMCR.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

Arm deprecates use of PMCR.D = 1.

On a Warm reset, this field resets to `0`.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

`0b0` No action.

`0b1` Reset PMCCNTR to zero.

This bit is always RAZ.

Note

Resetting PMCCNTR does not change the cycle counter overflow bit.

The value of PMCR_EL0.LC is ignored, and bits [63:0] of all event counters are reset.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

`0b0` No action.

`0b1` Reset all event counters accessible in the current Exception level, not including PMCCNTR, to zero.

This bit is always RAZ.

In EL0 and EL1:

- If EL2 is implemented and enabled in the current Security state, and HDCR.HPMN or MDCR_EL2.HPMN is less than PMCR_EL0.N, a write of 1 to this bit does not reset event counters in the range [HDCR.HPMN..(PMCR.N-1)] or [MDCR_EL2.HPMN..(PMCR.N-1)].
- If EL2 is not implemented, EL2 is disabled in the current Security state, or HDCR.HPMN or MDCR_EL2.HPMN is equal to PMCR_EL0.N, a write of 1 to this bit resets all the event counters.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Note

Resetting the event counters does not change the event counter overflow bits.

If ARMv8.5-PMU is implemented, the value of HDCR.HLP, or PMCR.LP is ignored and bits [63:0] of all affected event counters are reset.

E, bit [0]

Enable.

`0b0` All event counters in the range [0..(PMN-1)] and PMCCNTR, are disabled.

`0b1` All event counters in the range [0..(PMN-1)] and PMCCNTR, are enabled by PMCNTENSET.

This bit is RW.

If EL2 is implemented then:

- If EL2 is using AArch32, PMN is HDCR.HPMN.
- If EL2 is using AArch64, PMN is MDCR_EL2.HPMN.
- If PMN is less than PMCR.N, this bit does not affect the operation of event counters in the range [PMN..(PMCR.N-1)].

If EL2 is not implemented, PMN is PMCR.N.

Note

The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

On a Warm reset, this field resets to `0`.

Accessing the PMCR

Accesses to this register use the following encodings in the System instruction encoding space:

G8.4.10 PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configurations

AArch32 System register PMEVCNTR<n>[31:0] is architecturally mapped to AArch64 System register PMEVCNTR<n>_EL0[31:0].

AArch32 System register PMEVCNTR<n>[31:0] is architecturally mapped to External register PMEVCNTR<n>_EL0[31:0].

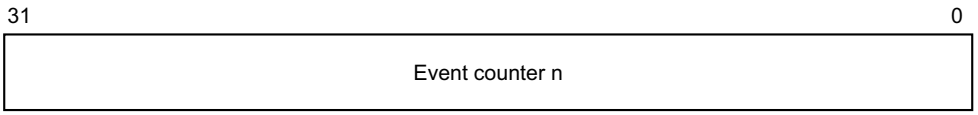
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVCNTR<n> is a 32-bit register.

Field descriptions

The PMEVCNTR<n> bit assignments are:



Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

If ARMv8.5-PMU is implemented, the event counter is 64 bits and only the least-significant part of the event counter is accessible in AArch32 state:

- Reads from PMEVCNTR<n> return bits [31:0] of the counter.
- Writes to PMEVCNTR<n> update bits [31:0] and leave bits [63:32] unchanged.
- There is no means to access bits [63:32] directly from AArch32 state.
- If the implementation does not support AArch64 at any Exception level, bits [63:32] are not required to be implemented.

If ARMv8.5-PMU is not implemented, the event counter is 32 bits.

This field resets to an architecturally UNKNOWN value.

Accessing the PMEVCNTR<n>

PMEVCNTR<n> can also be accessed by using PMXEVCNTR with PMSELR.SEL set to the value of <n>.

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

In EL0, an access is permitted if it is enabled by PMUSERENR.{ER,EN} or PMUSERENR_EL0.{ER,EN}.

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1110	0b10:n[4:3]	n[2:0]

G8.4.11 PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configurations

AArch32 System register PMEVTYPER<n>[31:0] is architecturally mapped to AArch64 System register PMEVTYPER<n>_EL0[31:0].

AArch32 System register PMEVTYPER<n>[31:0] is architecturally mapped to External register PMEVTYPER<n>_EL0[31:0].

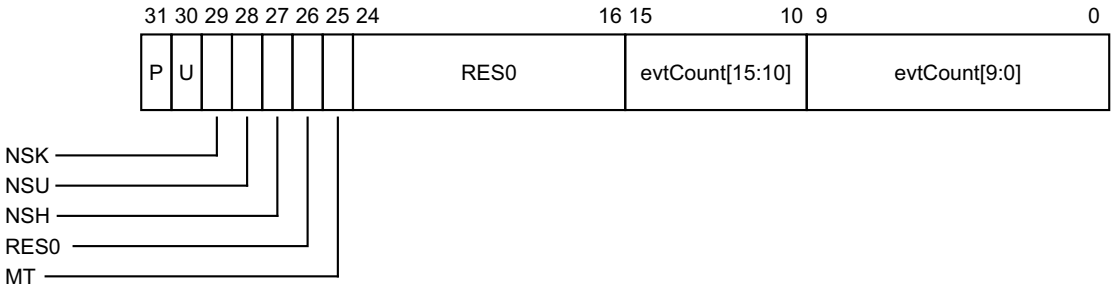
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVTYPER<n> is a 32-bit register.

Field descriptions

The PMEVTYPER<n> bit assignments are:



P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0b0` Count events in EL1.

`0b1` Do not count events in EL1.

This field resets to an architecturally UNKNOWN value.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0b0` Count events in EL0.

`0b1` Do not count events in EL0.

This field resets to an architecturally UNKNOWN value.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

This field resets to an architecturally UNKNOWN value.

NSH, bit [27]

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0b0` Do not count events in EL2.

`0b1` Count events in EL2.

This field resets to an architecturally UNKNOWN value.

Bit [26]

Reserved, RES0.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

`0b0` Count events only on controlling PE.

`0b1` Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

Note

- When the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach, an implementation is described as multi-threaded. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, when read at the highest implemented Exception level, the value of MPIDR_EL1.MT is 1.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

This field resets to an architecturally UNKNOWN value.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

When ARMv8.1-PMU is implemented:

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>.

Software must program this field with an event that is supported by the PE being programmed.

There are three types of event:

- Common architectural and microarchitectural events.
- Arm recommended common architectural and microarchitectural events.
- IMPLEMENTATION DEFINED events.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The ranges of event numbers allocated to each type of event are shown in Table D7-6 on page D7-2693.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range 0x000 to 0x03F, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

Arm recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

This field resets to an architecturally UNKNOWN value.

Accessing the PMEVTYPER<n>

PMEVTYPER<n> can also be accessed by using PMXEVTYPER with PMSELR.SEL set to n.

If <n> is greater or equal to the number of accessible counters, reads and writes of PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR.EN or PMUSERENR_EL0.EN.

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.4.12 PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

PMINTENCLR is used in conjunction with the PMINTENSET register.

Configurations

AArch32 System register PMINTENCLR[31:0] is architecturally mapped to AArch64 System register PMINTENCLR_EL1[31:0].

AArch32 System register PMINTENCLR[31:0] is architecturally mapped to External register PMINTENCLR_EL1[31:0].

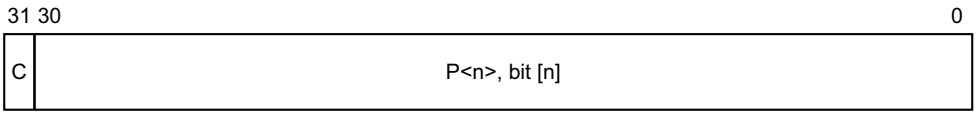
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENCLR is a 32-bit register.

Field descriptions

The PMINTENCLR bit assignments are:



C, bit [31]

PMCCNTR overflow interrupt request disable bit. Possible values are:

`0b0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`0b1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

`0b0` When read, means that the PMEVCNTR<n> event counter interrupt request is disabled. When written, has no effect.

`0b1` When read, means that the PMEVCNTR<n> event counter interrupt request is enabled. When written, disables the PMEVCNTR<n> interrupt request.

This field resets to an architecturally UNKNOWN value.

Accessing the PMINTENCLR

G8.4.13 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

PMINTENSET is used in conjunction with the PMINTENCLR register.

Configurations

AArch32 System register PMINTENSET[31:0] is architecturally mapped to AArch64 System register PMINTENSET_EL1[31:0].

AArch32 System register PMINTENSET[31:0] is architecturally mapped to External register PMINTENSET_EL1[31:0].

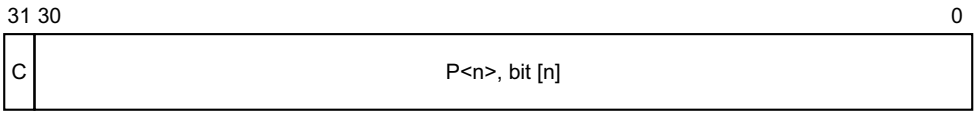
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENSET is a 32-bit register.

Field descriptions

The PMINTENSET bit assignments are:



C, bit [31]

PMCCNTR overflow interrupt request enable bit. Possible values are:

`0b0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`0b1` When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

`0b0` When read, means that the PMEVCNTR<n> event counter interrupt request is disabled. When written, has no effect.

`0b1` When read, means that the PMEVCNTR<n> event counter interrupt request is enabled. When written, enables the PMEVCNTR<n> interrupt request.

This field resets to an architecturally UNKNOWN value.

G8.4.14 PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<n>. Writing to this register clears these bits.

Configurations

AArch32 System register PMOVSR[31:0] is architecturally mapped to AArch64 System register PMOVSCLR_EL0[31:0].

AArch32 System register PMOVSR[31:0] is architecturally mapped to External register PMOVSCLR_EL0[31:0].

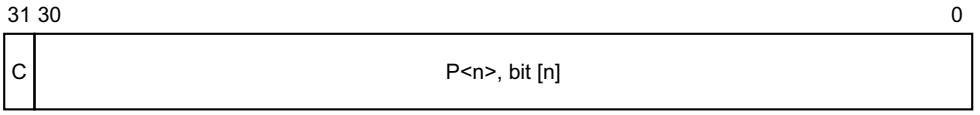
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSR is a 32-bit register.

Field descriptions

The PMOVSR bit assignments are:



C, bit [31]

Cycle counter overflow clear bit. Possible values are:

`0b0` When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means the cycle counter has overflowed since this bit was last cleared. When written, clears the cycle counter overflow bit to 0.

PMCR.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR[31:0] or unsigned overflow of PMCCNTR[63:0].

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow clear bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

`0b0` When read, means that PMEVCNTR<n> has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n> has overflowed since this bit was last cleared. When written, clears the PMEVCNTR<n> overflow bit to 0.

If ARMv8.5-PMU is implemented, MDCR_EL2.HLP, HDCR.HLP, and PMCR.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR<n>[31:0] or unsigned overflow of PMEVCNTR<n>[63:0]. PMEVCNTR<n>[63:32] cannot be accessed directly in AArch32 state.

This field resets to an architecturally UNKNOWN value.

G8.4.15 PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<n>.

Configurations

AArch32 System register PMOVSSET[31:0] is architecturally mapped to AArch64 System register PMOVSSET_EL0[31:0].

AArch32 System register PMOVSSET[31:0] is architecturally mapped to External register PMOVSSET_EL0[31:0].

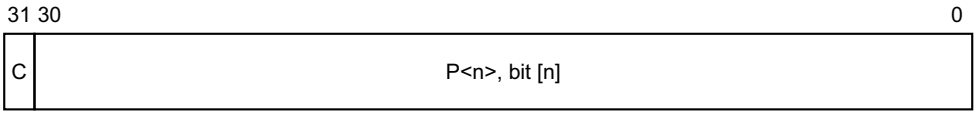
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSSET is a 32-bit register.

Field descriptions

The PMOVSSET bit assignments are:



C, bit [31]

Cycle counter overflow set bit.

`0b0` When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means the cycle counter has overflowed since this bit was last cleared. When written, sets the cycle counter overflow bit to 1.

PMCR.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR[31:0] or unsigned overflow of PMCCNTR[63:0].

This field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow set bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are RAZ/WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

`0b0` When read, means that PMEVCNTR<n> has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n> has overflowed since this bit was last . When written, sets the PMEVCNTR<n> overflow bit to 1.

If ARMv8.5-PMU is implemented, MDCR_EL2.HLP, HDCR.HLP, and PMCR.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR<n>[31:0] or unsigned overflow of PMEVCNTR<n>[63:0]. PMEVCNTR<n>[63:32] cannot be accessed directly in AArch32 state.

This field resets to an architecturally UNKNOWN value.

G8.4.16 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

Purpose

Selects the current event counter PMEVCNTR<n> or the cycle counter, CCNT.

PMSELR is used in conjunction with PMXEVTYPER to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCNTR, to determine the value of a selected event counter.

Configurations

AArch32 System register PMSELR[31:0] is architecturally mapped to AArch64 System register PMSELR_EL0[31:0].

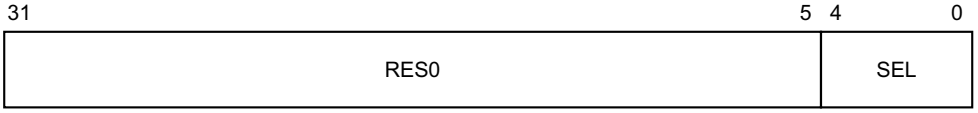
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSELR is a 32-bit register.

Field descriptions

The PMSELR bit assignments are:



Bits [31:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, PMEVCNTR<n>, where n is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER or PMXEVCNTR occurs.

This field can take any value from 0 (`0b00000`) to (PMCR.N)-1, or 31 (`0b11111`).

When PMSELR.SEL is `0b11111`, it selects the cycle counter and:

- A read of the PMXEVTYPER returns the value of PMCCFILTR.
- A write of the PMXEVTYPER writes to PMCCFILTR.
- A read or write of PMXEVCNTR has CONSTRAINED UNPREDICTABLE effects. See PMXEVCNTR for more details.

If this field is set to a value greater than or equal to the number of counters accessible at the current Exception level, but not equal to 31:

- Direct reads of this field return an UNKNOWN value.
- The results of access to PMXEVTYPER or PMXEVCNTR are CONSTRAINED UNPREDICTABLE. See PMXEVTYPER or PMXEVCNTR for more details.

For information about the number of counters accessible at each Exception level, see HDCR.HPMN and MDCR_EL2.HPMN.

This field resets to an architecturally UNKNOWN value.

G8.4.17 PMSWINC, Performance Monitors Software Increment register

The PMSWINC characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`. For more information, see SW_INCR.

Configurations

AArch32 System register PMSWINC[31:0] is architecturally mapped to AArch64 System register PMSWINC_EL0[31:0].

AArch32 System register PMSWINC[31:0] is architecturally mapped to External register PMSWINC_EL0[31:0].

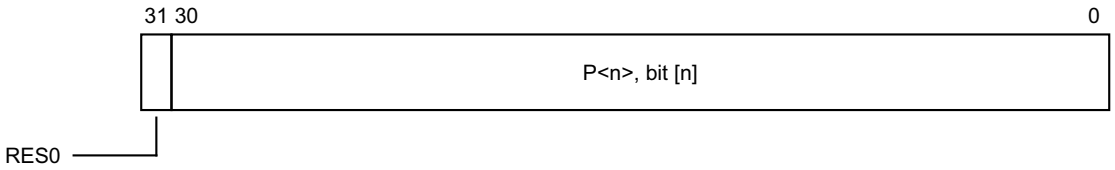
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSWINC is a 32-bit register.

Field descriptions

The PMSWINC bit assignments are:



Bit [31]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 30

Event counter software increment bit for PMEVCNTR<n>.

If N is less than 31, then bits [30:N] are WI. When EL2 is implemented and enabled in the current Security state, in EL1 and EL0, N is the value in MDCR_EL2.HPMN if EL2 is using AArch64, or in HDCR.HPMN if EL2 is using AArch32. Otherwise, N is the value in PMCR.N.

`0b0` No action. The write to this bit is ignored.

`0b1` If PMEVCNTR<n> is enabled and configured to count the software increment event, increments PMEVCNTR<n> by 1. If PMEVCNTR<n> is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC

Accesses to this register use the following encodings in the System instruction encoding space:

MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1001	0b1100	0b100

Purpose

Enables or disables User mode access to the Performance Monitors.

Configurations

AArch32 System register PMUSERENR[31:0] is architecturally mapped to AArch64 System register PMUSERENR_EL0[31:0].

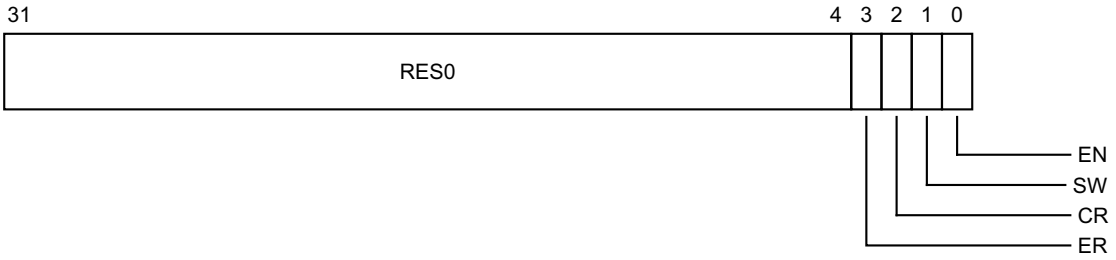
This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMUSERENR is a 32-bit register.

Field descriptions

The PMUSERENR bit assignments are:



Bits [31:4]

Reserved, RES0.

ER, bit [3]

Event counter read trap control:

0b0 EL0 reads of the PMXEVCNTR and PMEVCNTR<n>, and EL0 RW access to the PMSELR, are trapped to Undefined mode if PMUSERENR.EN is also 0.

0b1 Overrides PMUSERENR.EN and enables RO access to PMXEVCNTR and PMEVCNTR<n>, and RW access to PMSELR.

On a Warm reset, this field resets to 0.

CR, bit [2]

Cycle counter read trap control:

0b0 EL0 reads of the PMCCNTR are trapped to Undefined mode if PMUSERENR.EN is also 0.

0b1 Overrides PMUSERENR.EN and enables access to PMCCNTR.

On a Warm reset, this field resets to 0.

SW, bit [1]

Software increment write trap control:

0b0 EL0 writes to the PMSWINC are trapped to Undefined mode if PMUSERENR.EN is also 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` Overrides PMUSERENR.EN and enables access to PMSWINC.

On a Warm reset, this field resets to `0`.

EN, bit [0]

Traps EL0 accesses to the Performance Monitors registers to Undefined mode:

`0b0` While at EL0, PMUSERENR is always RO. Accesses to the other Performance Monitors registers are trapped to Undefined mode, unless enabled by one of PMUSERENR.{ER, CR, SW}.

`0b1` While at EL0, software can access all PMU registers except PMINTENSET and PMINTENCLR.

On a Warm reset, this field resets to `0`.

Accessing the PMUSERENR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.4.19 PMXEVCNTR, Performance Monitors Selected Event Count Register

The PMXEVCNTR characteristics are:

Purpose

Reads or writes the value of the selected event counter, PMEVCNTR<n>. PMSELR.SEL determines which event counter is selected.

Configurations

AArch32 System register PMXEVCNTR[31:0] is architecturally mapped to AArch64 System register PMXEVCNTR_EL0[31:0].

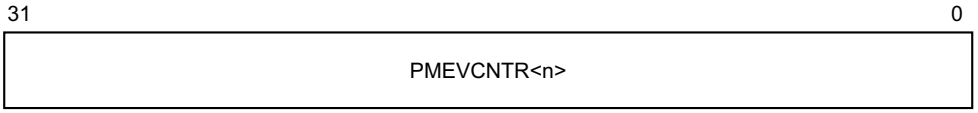
This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMXEVCNTR is a 32-bit register.

Field descriptions

The PMXEVCNTR bit assignments are:



PMEVCNTR<n>, bits [31:0]

Value of the selected event counter, PMEVCNTR<n>, where n is the value stored in PMSELR.SEL.

If ARMv8.5-PMU is implemented, the event counter is 64 bits and only the least-significant part of the event counter is accessible in AArch32 state:

- Reads from PMXEVCNTR return bits [31:0] of the counter.
- Writes to PMXEVCNTR update bits [31:0] and leave bits [63:32] unchanged.
- There is no means to access bits [63:32] directly from AArch32 state.
- If the implementation does not support AArch64 at any Exception level, bits [63:32] are not required to be implemented.

If ARMv8.5-PMU is not implemented, the event counter is 32 bits.

This field resets to an architecturally UNKNOWN value.

Accessing the PMXEVCNTR

If PMSELR.SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVCNTR are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- Accesses to the register behave as if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- If EL2 is implemented and enabled in the current Security state, and PMSELR.SEL is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

In EL0, an access is permitted if it is enabled by PMUSERENR.{ER,EN} or PMUSERENR_EL0.{ER,EN}.

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.4.20 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

Purpose

When PMSELR.SEL selects an event counter, this accesses a PMEVTYPER<n> register. When PMSELR.SEL selects the cycle counter, this accesses PMCCFILTR.

Configurations

AArch32 System register PMXEVTYPER[31:0] is architecturally mapped to AArch64 System register PMXEVTYPER_EL0[31:0].

When the value of PMSELR.SEL is 31, to select the cycle counter, RW fields in this register have defined reset values that apply only when the PE resets into an Exception level that is using AArch32. See PMCCFILTR for the reset values.

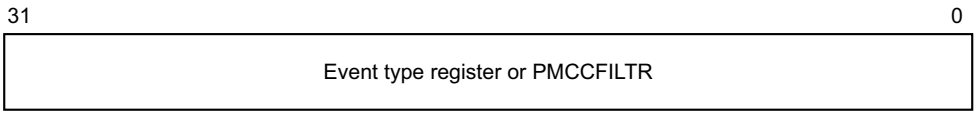
Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN. This applies whenever PMSELR.SEL selects an event counter.

Attributes

PMXEVTYPER is a 32-bit register.

Field descriptions

The PMXEVTYPER bit assignments are:



Bits [31:0]

Event type register or PMCCFILTR.

When PMSELR.SEL == 31, this register accesses PMCCFILTR.

Otherwise, this register accesses PMEVTYPER<n> where n is the value in PMSELR.SEL.

Accessing the PMXEVTYPER

If PMSELR.SEL is not 31, and is greater than or equal to the number of accessible counters then reads and writes of PMXEVTYPER are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`
- Accesses to the register behave as if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR.SEL is 31.
- If EL2 is implemented and enabled in the current Security state, and PMSELR.SEL is less than the number of implemented counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR.EN or PMUSERENR_EL0.EN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1:

- If EL2 is using AArch32, HDCR.HPMN identifies the number of accessible counters.
- If EL2 is using AArch64, MDCR_EL2.HPMN identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters. See HDCR.HPMN and MDCR_EL2.HPMN for more details.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.5 Activity Monitors registers

This section lists the Activity Monitoring registers in AArch32.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

G8.5.1 AMCFGR, Activity Monitors Configuration Register

The AMCFGR characteristics are:

Purpose

Global configuration register for the activity monitors.

Provides information on supported features, the number of counter groups implemented, the total number of activity monitor event counters implemented, and the size of the counters. AMCFGR is applicable to both the architected and the auxiliary counter groups.

Configurations

AArch32 System register AMCFGR[31:0] is architecturally mapped to AArch64 System register AMCFGR_EL0[31:0].

AArch32 System register AMCFGR[31:0] is architecturally mapped to External register AMCFGR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCFGR are UNDEFINED.

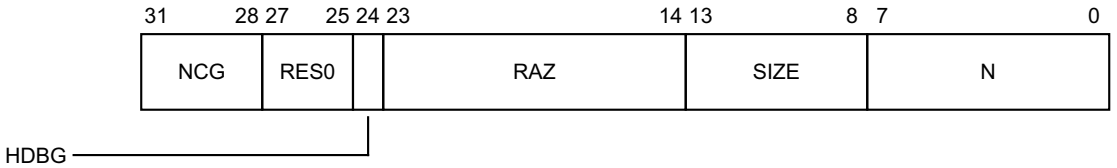
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCFGR is a 32-bit register.

Field descriptions

The AMCFGR bit assignments are:



NCG, bits [31:28]

Defines the number of counter groups.

The number of implemented counter groups is defined as [AMCFGR.NCG + 1].

If the number of implemented auxiliary activity monitor event counters is zero, this field has a value of `0b0000`. Otherwise, this field has a value of `0b0001`.

Bits [27:25]

Reserved, RES0.

HDBG, bit [24]

Halt-on-debug supported.

From Armv8, this feature must be supported, and so this bit is `0b1`.

`0b0` AMCR.HDBG is RES0.

`0b1` AMCR.HDBG is read/write.

Bits [23:14]

Reserved, RAZ.

SIZE, bits [13:8]

Defines the size of activity monitor event counters.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The size of the activity monitor event counters implemented by the Activity Monitors Extension is defined as [AMCFGR.SIZE + 1].

From Armv8, the counters are 64-bit, and so this field is `0b111111`.

Note

Software also uses this field to determine the spacing of counters in the memory-map. From Armv8, the counters are at doubleword-aligned addresses.

N, bits [7:0]

Defines the number of activity monitor event counters.

The total number of counters implemented in all groups by the Activity Monitors Extension is defined as [AMCFGR.N + 1].

Accessing the AMCFGR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.5.2 AMCGCR, Activity Monitors Counter Group Configuration Register

The AMCGCR characteristics are:

Purpose

Provides information on the number of activity monitor event counters implemented within each counter group.

Configurations

AArch32 System register AMCGCR[31:0] is architecturally mapped to AArch64 System register AMCGCR_EL0[31:0].

AArch32 System register AMCGCR[31:0] is architecturally mapped to External register AMCGCR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCGCR are UNDEFINED.

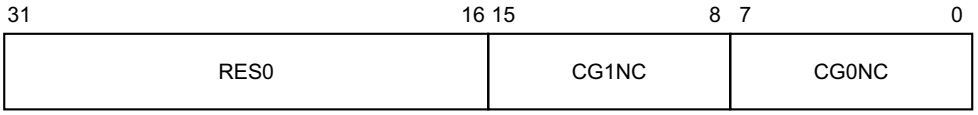
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCGCR is a 32-bit register.

Field descriptions

The AMCGCR bit assignments are:



Bits [31:16]

Reserved, RES0.

CG1NC, bits [15:8]

Counter Group 1 Number of Counters. The number of counters in the auxiliary counter group.

In AMUv1, the permitted range of values is 0 to 16.

CG0NC, bits [7:0]

Counter Group 0 Number of Counters. The number of counters in the architected counter group.

In AMUv1, the value of this field is 4.

Accessing the AMCGCR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.5.3 AMCNTENCLR0, Activity Monitors Count Enable Clear Register 0

The AMCNTENCLR0 characteristics are:

Purpose

Disable control bits for the architected activity monitors event counters, AMEVCNTR0<n>.

Configurations

AArch32 System register AMCNTENCLR0[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR0_EL0[31:0].

AArch32 System register AMCNTENCLR0[31:0] is architecturally mapped to External register AMCNTENCLR0[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR0 are UNDEFINED.

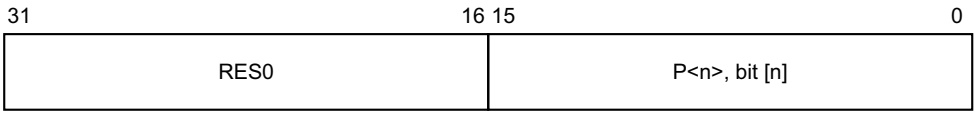
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCNTENCLR0 is a 32-bit register.

Field descriptions

The AMCNTENCLR0 bit assignments are:



Bits [31:16]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 15

Activity monitor event counter disable bit for AMEVCNTR0<n>.

Bits [31:16] are RES0. Bits [15:N] are RAZ/WI. N is the value in AMCGCR.CG0NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR0<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR0<n> is enabled. When written, disables AMEVCNTR0<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENCLR0

Accesses to this register use the following encodings in the System instruction encoding space:

G8.5.4 AMCNTENCLR1, Activity Monitors Count Enable Clear Register 1

The AMCNTENCLR1 characteristics are:

Purpose

Disable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

Configurations

AArch32 System register AMCNTENCLR1[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR1_EL0[31:0].

AArch32 System register AMCNTENCLR1[31:0] is architecturally mapped to External register AMCNTENCLR1[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR1 are UNDEFINED.

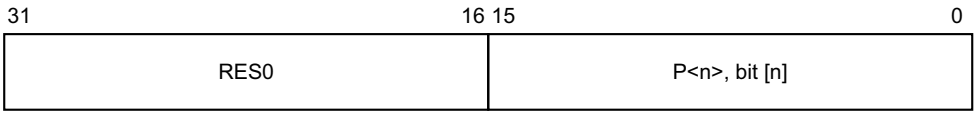
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCNTENCLR1 is a 32-bit register.

Field descriptions

The AMCNTENCLR1 bit assignments are:



Bits [31:16]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 15

Activity monitor event counter disable bit for AMEVCNTR1<n>.

Bits [31:16] are RES0. Bits [15:N] are RAZ/WI. N is the value in AMCGCR_EL0.CG1NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR1<n> is enabled. When written, disables AMEVCNTR1<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENCLR1

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

G8.5.5 AMCNTENSET0, Activity Monitors Count Enable Set Register 0

The AMCNTENSET0 characteristics are:

Purpose

Enable control bits for the architected activity monitors event counters, AMEVCNTR0<n>.

Configurations

AArch32 System register AMCNTENSET0[31:0] is architecturally mapped to AArch64 System register AMCNTENSET0_EL0[31:0].

AArch32 System register AMCNTENSET0[31:0] is architecturally mapped to External register AMCNTENSET0[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET0 are UNDEFINED.

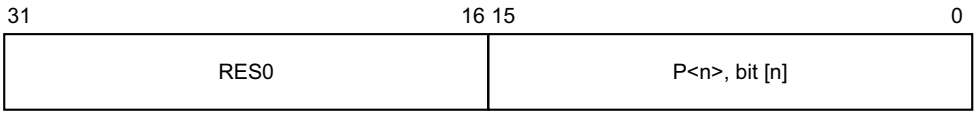
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCNTENSET0 is a 32-bit register.

Field descriptions

The AMCNTENSET0 bit assignments are:



Bits [31:16]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 15

Activity monitor event counter enable bit for AMEVCNTR0<n>.

Bits [31:16] are RES0. Bits [15:N] are RAZ/WI. N is the value in AMCGCR.CG0NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR0<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR0<n> is enabled. When written, enables AMEVCNTR0<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENSET0

Accesses to this register use the following encodings in the System instruction encoding space:

G8.5.6 AMCNTENSET1, Activity Monitors Count Enable Set Register 1

The AMCNTENSET1 characteristics are:

Purpose

Enable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

Configurations

AArch32 System register AMCNTENSET1[31:0] is architecturally mapped to AArch64 System register AMCNTENSET1_EL0[31:0].

AArch32 System register AMCNTENSET1[31:0] is architecturally mapped to External register AMCNTENSET1[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET1 are UNDEFINED.

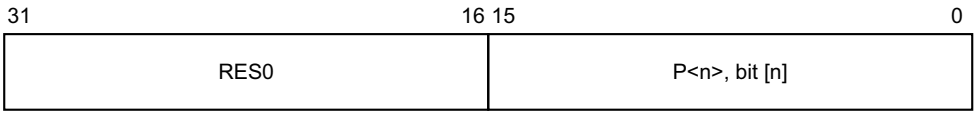
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCNTENSET1 is a 32-bit register.

Field descriptions

The AMCNTENSET1 bit assignments are:



Bits [31:16]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 15

Activity monitor event counter enable bit for AMEVCNTR1<n>.

Bits [31:16] are RES0. Bits [15:N] are RAZ/WI. N is the value in AMCGCR.CG1NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR1<n> is enabled. When written, enables AMEVCNTR1<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENSET1

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENSET1 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

G8.5.7 AMCR, Activity Monitors Control Register

The AMCR characteristics are:

Purpose

Global control register for the activity monitors implementation. AMCR is applicable to both the architected and the auxiliary counter groups.

Configurations

AArch32 System register AMCR[31:0] is architecturally mapped to AArch64 System register AMCR_EL0[31:0].

AArch32 System register AMCR[31:0] is architecturally mapped to External register AMCR[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCR are UNDEFINED.

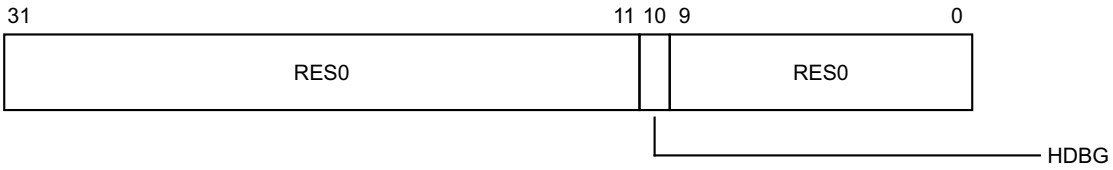
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMCR is a 32-bit register.

Field descriptions

The AMCR bit assignments are:



Bits [31:11]

Reserved, RES0.

HDBG, bit [10]

This bit controls whether activity monitor counting is halted when the PE is halted in Debug state.

`0b0` Activity monitors do not halt counting when the PE is halted in Debug state.

`0b1` Activity monitors halt counting when the PE is halted in Debug state.

Bits [9:0]

Reserved, RES0.

Accessing the AMCR

Accesses to this register use the following encodings in the System instruction encoding space:

G8.5.8 AMEVCNTR0<n>, Activity Monitors Event Counter Registers 0, n = 0 - 15

The AMEVCNTR0<n> characteristics are:

Purpose

Provides access to the architected activity monitor event counters.

Configurations

AArch32 System register AMEVCNTR0<n>[63:0] is architecturally mapped to AArch64 System register AMEVCNTR0<n>_EL0[63:0].

AArch32 System register AMEVCNTR0<n>[63:0] is architecturally mapped to External register AMEVCNTR0<n>[63:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR0<n> are UNDEFINED.

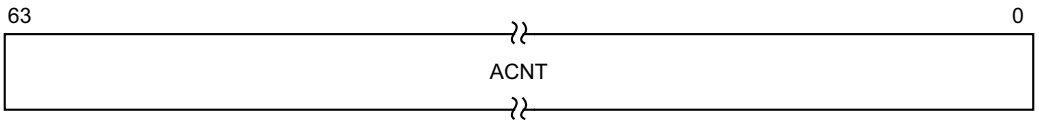
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMEVCNTR0<n> is a 64-bit register.

Field descriptions

The AMEVCNTR0<n> bit assignments are:



ACNT, bits [63:0]

Architected activity monitor event counter n.

Value of architected activity monitor event counter n, where n is the number of this register and is a number from 0 to 15.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to `0`.

Accessing the AMEVCNTR0<n>

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

Note

AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.5.10 AMEVTYPER0<n>, Activity Monitors Event Type Registers 0, n = 0 - 15

The AMEVTYPER0<n> characteristics are:

Purpose

Provides information on the events that an architected activity monitor event counter AMEVCNTR0<n> counts.

Configurations

AArch32 System register AMEVTYPER0<n>[31:0] is architecturally mapped to AArch64 System register AMEVTYPER0<n>_EL0[31:0].

AArch32 System register AMEVTYPER0<n>[31:0] is architecturally mapped to External register AMEVTYPER0<n>[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPER0<n> are UNDEFINED.

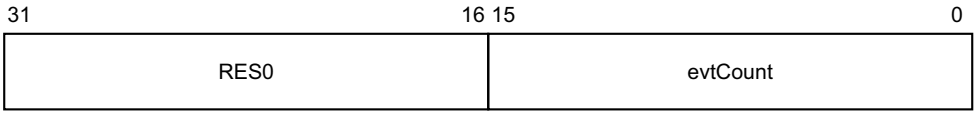
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMEVTYPER0<n> is a 32-bit register.

Field descriptions

The AMEVTYPER0<n> bit assignments are:



Bits [31:16]

Reserved, RES0.

evtCount, bits [15:0]

Event to count. The event number of the event that is counted by the architected activity monitor event counter AMEVCNTR0<n>. The value of this field is architecturally mandated for each architected counter.

The following table shows the mapping between required event numbers and the corresponding counters:

`0x0011` **When n == 0** Processor frequency cycles

`0x4004` **When n == 1** Constant frequency cycles

`0x0008` **When n == 2** Instructions retired

`0x4005` **When n == 3** Memory stall cycles

Accessing the AMEVTYPER0<n>

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVTYPER0<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

G8.5.11 AMEVTYPER1<n>, Activity Monitors Event Type Registers 1, n = 0 - 15

The AMEVTYPER1<n> characteristics are:

Purpose

Provides information on the events that an auxiliary activity monitor event counter AMEVCNTR1<n> counts.

Configurations

AArch32 System register AMEVTYPER1<n>[31:0] is architecturally mapped to AArch64 System register AMEVTYPER1<n>_EL0[31:0].

AArch32 System register AMEVTYPER1<n>[31:0] is architecturally mapped to External register AMEVTYPER1<n>[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPER1<n> are UNDEFINED.

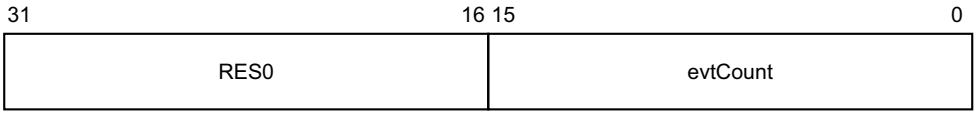
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMEVTYPER1<n> is a 32-bit register.

Field descriptions

The AMEVTYPER1<n> bit assignments are:



Bits [31:16]

Reserved, RES0.

evtCount, bits [15:0]

Event to count. The event number of the event that is counted by the auxiliary activity monitor event counter AMEVCNTR1<n>.

It is IMPLEMENTATION DEFINED what values are supported by each counter.

If software writes a value to this field which is not supported by the corresponding counter AMEVCNTR1<n>, then:

- It is UNPREDICTABLE which event will be counted.
- The value read back is UNKNOWN.

The event counted by AMEVCNTR1<n> might be fixed at implementation. In this case, the field is read-only and writes are UNDEFINED.

If the corresponding counter AMEVCNTR1<n> is enabled, writes to this register have UNPREDICTABLE results.

Accessing the AMEVTYPER1<n>

If <n> is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVTYPER1<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

G8.5.12 AMUSERENR, Activity Monitors User Enable Register

The AMUSERENR characteristics are:

Purpose

Global user enable register for the activity monitors. Enables or disables EL0 access to the activity monitors. AMUSERENR is applicable to both the architected and the auxiliary counter groups.

Configurations

AArch32 System register AMUSERENR[31:0] is architecturally mapped to AArch64 System register AMUSERENR_EL0[31:0].

This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMUSERENR are UNDEFINED.

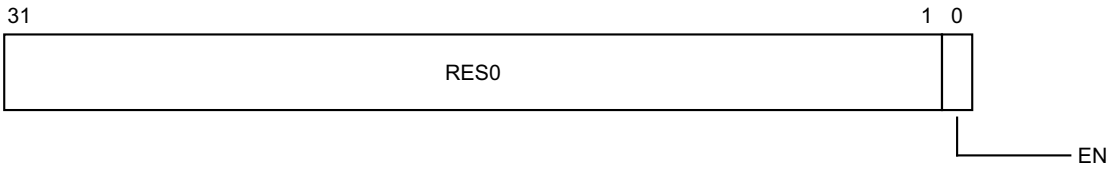
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMUSERENR is a 32-bit register.

Field descriptions

The AMUSERENR bit assignments are:



Bits [31:1]

Reserved, RES0.

EN, bit [0]

Traps EL0 accesses to the activity monitors registers to EL1.

`0b0` EL0 accesses to the activity monitors registers are trapped to EL1.

`0b1` This control does not cause any instructions to be trapped. Software can access all activity monitor registers at EL0.

Note

- AMUSERENR can always be read at EL0 and is not governed by this bit.

Accessing the AMUSERENR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.6.1 DISR, Deferred Interrupt Status Register

The DISR characteristics are:

Purpose

Records that an SError interrupt has been consumed by an ESB instruction.

Configurations

AArch32 System register DISR[31:0] is architecturally mapped to AArch64 System register DISR_EL1[31:0] when the highest implemented Exception level is using AArch64.

This register is present only when RAS is implemented. Otherwise, direct accesses to DISR are UNDEFINED.

RW fields in this register reset to architecturally UNKNOWN values.

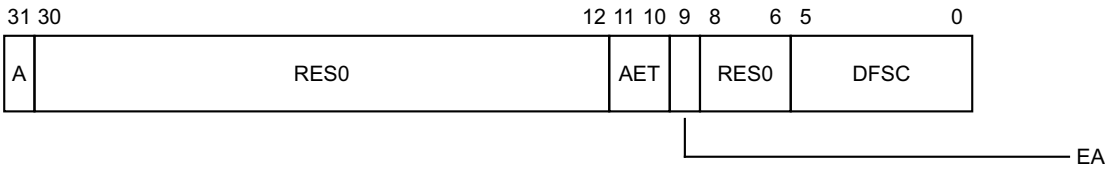
Attributes

DISR is a 32-bit register.

Field descriptions

The DISR bit assignments are:

When the ESB instruction is executed at EL2:



A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Bits [30:12]

Reserved, RES0.

AET, bits [11:10]

Asynchronous Error Type. See the description of HSR.AET for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort Type. See the description of HSR.EA for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

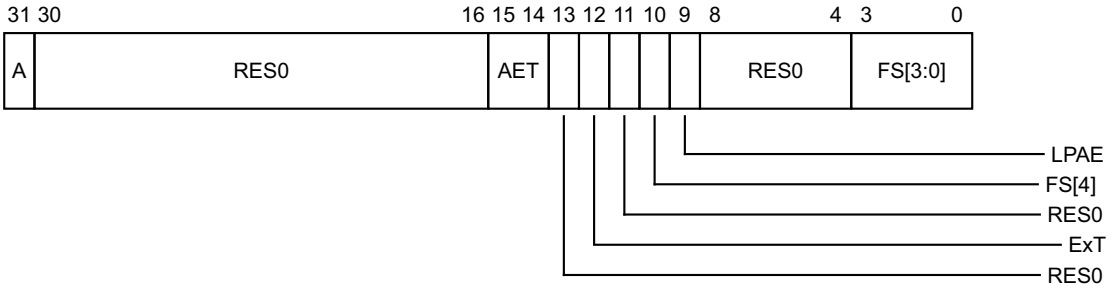
DFSC, bits [5:0]

Fault Status Code. See the description of HSR.DFSC for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the ESB instruction is executed at EL0 or EL1 and where TTBCR.EAE == 0:



A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

Asynchronous Error Type. See the description of DFSR.AET for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

External abort Type. See the description of DFSR.ExT for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES0.

FS[4], bit [10]

This field is bit[4] of FS[4:0].

Fault Status Code. See the description of DFSR.FS for an SError interrupt.

The FS field is split as follows:

- FS[4] is DISR[10].
- FS[3:0] is DISR[3:0].

This field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

Format.

`0b0` Using the Short-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

Bits [8:4]

Reserved, RES0.

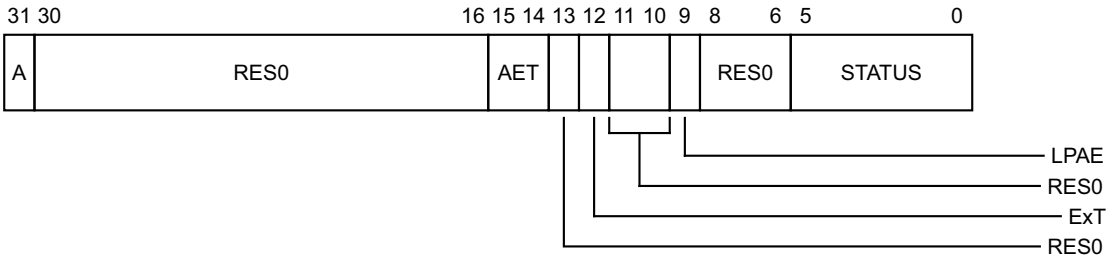
Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FS[3:0], bits [3:0]

This field is bits[3:0] of FS[4:0].

See FS[4] for the field description.

When the ESB instruction is executed at EL0 or EL1 and where TTBCR.EAE == 1:



A, bit [31]

Set to 1 when an `ESB` instruction defers an asynchronous SError interrupt. If the implementation does not include any sources of SError interrupt that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

This field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

Asynchronous Error Type. See the description of DFSR.AET for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

External abort Type. See the description of DFSR.ExT for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

Format.

`0b1` Using the Long-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault Status Code. See the description of DFSR.DFSC for an SError interrupt.

This field resets to an architecturally UNKNOWN value.

Accessing the DISR

An indirect write to DISR made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR occurring in program order after the ESB instruction.

DISR is RAZ/WI if EL3 is implemented, the PE is in Non-debug state, and any of the following apply:

- EL3 is using AArch64, SCR_EL3.EA == 1, and any of the following apply:
  - The PE is executing at EL2.
  - The PE is executing at EL1 and ((SCR_EL3.NS == 0 && SCR_EL3.EEL2 == 0) || HCR_EL2.AMO == 0).
- EL3 is using AArch32, SCR.EA == 1, and any of the following apply:
  - The PE is executing at EL2.
  - The PE is executing at EL1 and (SCR.NS == 0 || HCR.AMO == 0).

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1100	0b0001	0b001

```

G8.6.2 ERRIDR, Error Record ID Register

The ERRIDR characteristics are:

Purpose

Defines the highest numbered index of the error records that can be accessed through the Error Record System registers.

Configurations

AArch32 System register ERRIDR[31:0] is architecturally mapped to AArch64 System register ERRIDR_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRIDR are UNDEFINED.

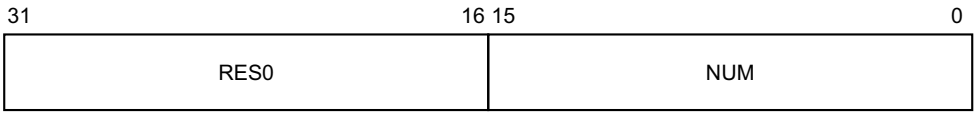
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERRIDR is a 32-bit register.

Field descriptions

The ERRIDR bit assignments are:



Bits [31:16]

Reserved, RES0.

NUM, bits [15:0]

Highest numbered index of the records that can be accessed through the Error Record System registers plus one. Zero indicates that no records can be accessed through the Error Record System registers.

Each implemented record is owned by a node. A node might own multiple records.

Accessing the ERRIDR

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b0101	0b0011	0b000

```

G8.6.3 ERRSELR, Error Record Select Register

The ERRSELR characteristics are:

Purpose

Selects an error record to be accessed through the Error Record System registers.

Configurations

AArch32 System register ERRSELR[31:0] is architecturally mapped to AArch64 System register ERRSELR_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRSELR are UNDEFINED.

If ERRIDR indicates that zero error records are implemented, then it is IMPLEMENTATION DEFINED whether ERRSELR is UNDEFINED or RES0.

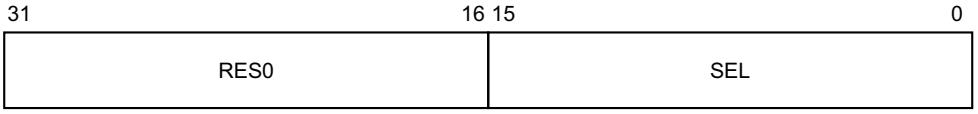
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERRSELR is a 32-bit register.

Field descriptions

The ERRSELR bit assignments are:



Bits [31:16]

Reserved, RES0.

SEL, bits [15:0]

Selects the error record accessed through the ERX registers.

If ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then all of the following apply:

- The value read back from ERRSELR.SEL is UNKNOWN.
- One of the following occurs:
  - An UNKNOWN error record is selected.
  - The ERX* registers are RAZ/WI.
  - ERX* register reads and writes are NOPs.
  - ERX* register reads and writes are UNDEFINED.

This field resets to an architecturally UNKNOWN value.

Accessing the ERRSELR

Accesses to this register use the following encodings in the System instruction encoding space:

G8.6.4 ERXADDR, Selected Error Record Address Register

The ERXADDR characteristics are:

Purpose

Accesses bits [31:0] of ERR<n>ADDR for the error record selected by ERRSELR.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch32 System register ERXADDR[31:0] is architecturally mapped to AArch64 System register ERXADDR_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXADDR are UNDEFINED.

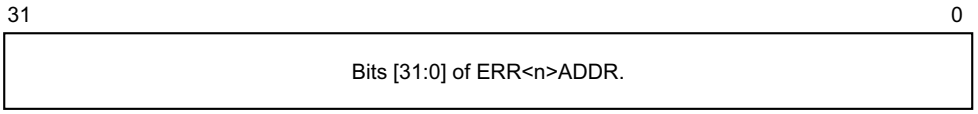
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXADDR is a 32-bit register.

Field descriptions

The ERXADDR bit assignments are:



Bits [31:0]

ERXADDR accesses bits [31:0] of ERR<n>ADDR, where n is the value in ERRSELR.SEL.

Accessing the ERXADDR

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

G8.6.5 ERXADDR2, Selected Error Record Address Register 2

The ERXADDR2 characteristics are:

Purpose

Accesses bits [63:32] of ERR<n>ADDR for the error record selected by ERRSELR.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch32 System register ERXADDR2[31:0] is architecturally mapped to AArch64 System register ERXADDR_EL1[63:32].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXADDR2 are UNDEFINED.

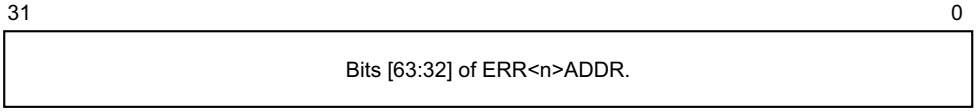
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXADDR2 is a 32-bit register.

Field descriptions

The ERXADDR2 bit assignments are:



Bits [31:0]

ERXADDR2 accesses bits [63:32] of ERR<n>ADDR, where n is the value in ERRSELR.SEL.

Accessing the ERXADDR2

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXADDR2 is RAZ/WI.
- Direct reads and writes of ERXADDR2 are NOPs.
- Direct reads and writes of ERXADDR2 are UNDEFINED.

G8.6.6 ERXCTLR, Selected Error Record Control Register

The ERXCTLR characteristics are:

Purpose

Accesses bits [31:0] of ERR<n>CTLR for the error record selected by ERRSELR.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch32 System register ERXCTLR[31:0] is architecturally mapped to AArch64 System register ERXCTLR_EL1[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXCTLR are UNDEFINED.

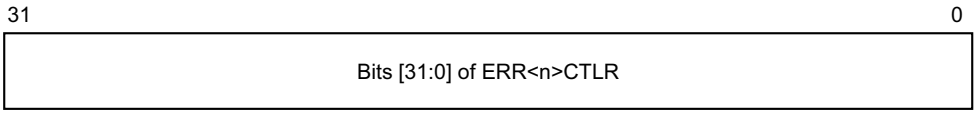
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXCTLR is a 32-bit register.

Field descriptions

The ERXCTLR bit assignments are:



Bits [31:0]

ERXCTLR accesses bits [31:0] of ERR<n>CTLR, where n is the value in ERRSELR.SEL.

Accessing the ERXCTLR

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXCTLR is RAZ/WI.
- Direct reads and writes of ERXCTLR are NOPs.
- Direct reads and writes of ERXCTLR are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.6.11 ERXMISC1, Selected Error Record Miscellaneous Register 1

The ERXMISC1 characteristics are:

Purpose

Accesses bits [63:32] of ERR<n>MISC0 for the error record selected by ERRSELR.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch32 System register ERXMISC1[31:0] is architecturally mapped to AArch64 System register ERXMISC0_EL1[63:32].

This register is present only when RAS is implemented. Otherwise, direct accesses to ERXMISC1 are UNDEFINED.

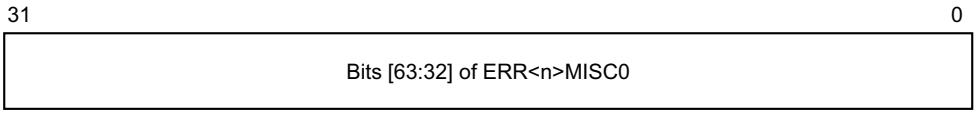
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXMISC1 is a 32-bit register.

Field descriptions

The ERXMISC1 bit assignments are:



Bits [31:0]

ERXMISC1 accesses bits [63:32] of ERR<n>MISC0, where n is the value in ERRSELR.SEL.

Accessing the ERXMISC1

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXMISC1 is RAZ/WI.
- Direct reads and writes of ERXMISC1 are NOPs.
- Direct reads and writes of ERXMISC1 are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.6.15 ERXMISC5, Selected Error Record Miscellaneous Register 5

The ERXMISC5 characteristics are:

Purpose

Accesses bits [63:32] of ERR<n>MISC2 for the error record selected by ERRSELR.SEL.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

AArch32 System register ERXMISC5[31:0] is architecturally mapped to AArch64 System register ERXMISC2_EL1[63:32].

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERXMISC5 are UNDEFINED.

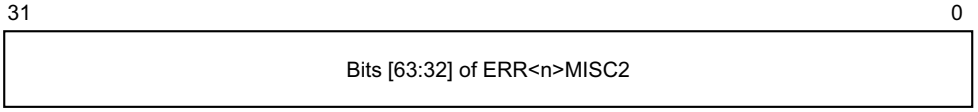
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ERXMISC5 is a 32-bit register.

Field descriptions

The ERXMISC5 bit assignments are:



Bits [31:0]

ERXMISC5 accesses bits [63:32] of ERR<n>MISC2, where n is the value in ERRSELR.SEL.

Accessing the ERXMISC5

If ERRIDR.NUM == 0 or ERRSELR.SEL is set to a value greater than or equal to ERRIDR.NUM, then one of the following occurs:

- An UNKNOWN record is selected.
- ERXMISC5 is RAZ/WI.
- Direct reads and writes of ERXMISC5 are NOPs.
- Direct reads and writes of ERXMISC5 are UNDEFINED.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.6.19 VDFSR, Virtual SError Exception Syndrome Register

The VDFSR characteristics are:

Purpose

Provides the syndrome value reported to software on taking a virtual SError interrupt exception to EL1, or on executing an ESB instruction at EL1.

When a virtual SError interrupt is taken, the syndrome value is reported in DFSR.{AET, ExT} and the remainder of the DFSR is set as defined by VMSAv8-32. For more information, see Chapter G5 *The AArch32 Virtual Memory System Architecture*.

If the virtual SError interrupt is deferred by an ESB instruction, then the syndrome value is written to VDISR.

Configurations

AArch32 System register VDFSR[31:0] is architecturally mapped to AArch64 System register VSESR_EL2[31:0] when the highest implemented Exception level is using AArch64.

This register is present only when RAS is implemented. Otherwise, direct accesses to VDFSR are UNDEFINED.

If EL2 is not implemented, then VDFSR is RES0 from Monitor mode when SCR.NS == 1.

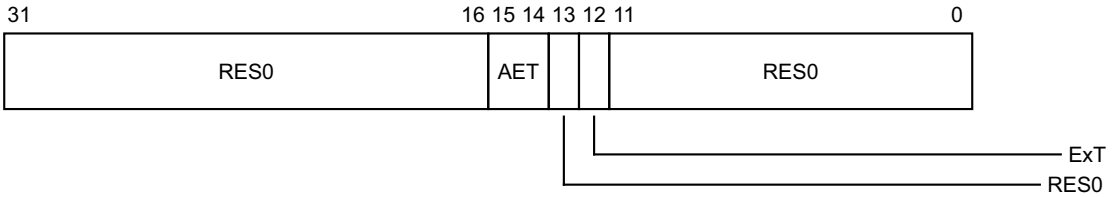
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VDFSR is a 32-bit register.

Field descriptions

The VDFSR bit assignments are:



Bits [31:16]

Reserved, RES0.

AET, bits [15:14]

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[15:4] is set to VDFSR.AET.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR[15:4] is set to VDFSR.AET.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

When a virtual SError interrupt is taken to EL1 using AArch32, DFSR[12] is set to VDFSR.ExT.

When a virtual SError interrupt is deferred by an ESB instruction, VDISR[12] is set to VDFSR.ExT.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

G8.6.20 VDISR, Virtual Deferred Interrupt Status Register

The VDISR characteristics are:

Purpose

Records that an SError interrupt has been consumed by an ESB instruction.

Configurations

AArch32 System register VDISR[31:0] is architecturally mapped to AArch64 System register VDISR_EL2[31:0].

This register is present only when RAS is implemented. Otherwise, direct accesses to VDISR are UNDEFINED.

If EL2 is not implemented, then VDISR is RES0 from Monitor mode when SCR.NS == 1.

RW fields in this register reset to architecturally UNKNOWN values.

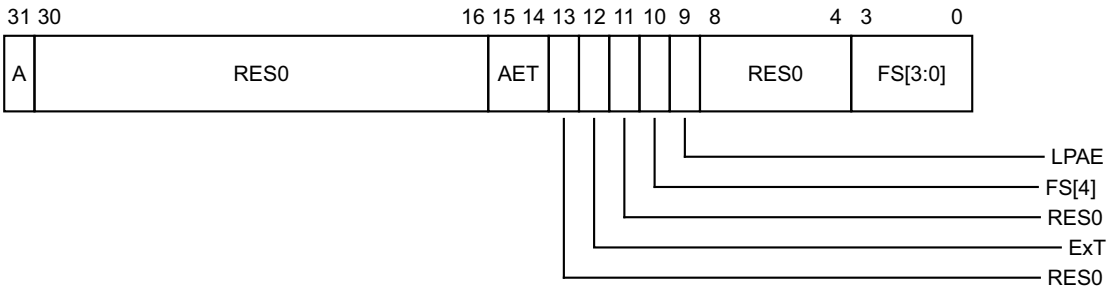
Attributes

VDISR is a 32-bit register.

Field descriptions

The VDISR bit assignments are:

When TTBCR.EAE == 0:



A, bit [31]

Set to 1 when an ESB instruction defers a virtual SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

The value copied from VDFSR.AET.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

The value copied from VDFSR.ExT.

This field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FS[4], bit [10]

This field is bit[4] of FS[4:0].

Fault status code. Set to `0b10110` when an `ESB` instruction defers a virtual SError interrupt.

`0b10110` Asynchronous SError interrupt.

All other values are reserved.

The FS field is split as follows:

- FS[4] is VDISR[10].
- FS[3:0] is VDISR[3:0].

This field resets to an architecturally UNKNOWN value.

LPAE, bit [9]

Format.

Set to TTBCR.EAE when an `ESB` instruction defers a virtual SError interrupt.

`0b0` Using the Short-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

Bits [8:4]

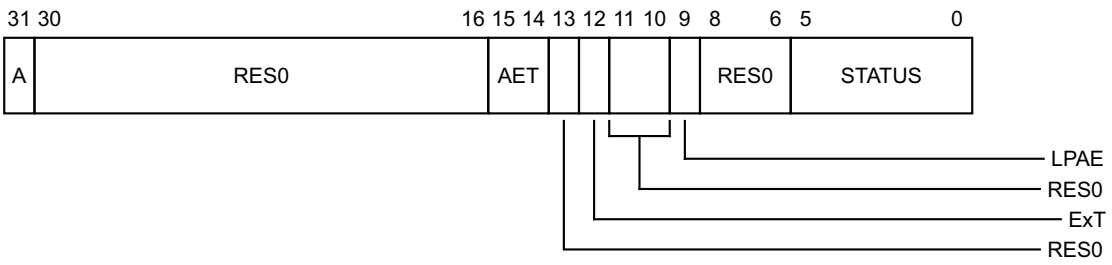
Reserved, RES0.

FS[3:0], bits [3:0]

This field is bits[3:0] of FS[4:0].

See FS[4] for the field description.

When TTBCR.EAE == 1:



A, bit [31]

Set to 1 when an `ESB` instruction defers a virtual SError interrupt.

This field resets to an architecturally UNKNOWN value.

Bits [30:16]

Reserved, RES0.

AET, bits [15:14]

The value copied from VDFSR.AET.

This field resets to an architecturally UNKNOWN value.

Bit [13]

Reserved, RES0.

ExT, bit [12]

The value copied from VDFSR.ExT.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

Format.

Set to TTBCR.EAE when an ESB instruction defers a virtual SError interrupt.

0b1 Using the Long-descriptor translation table format.

This field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status code. Set to 0b010001 when an ESB instruction defers a virtual SError interrupt.

0b010001 Asynchronous SError interrupt.

All other values are reserved.

This field resets to an architecturally UNKNOWN value.

Accessing the VDISR

Direct reads and writes of VDFSR are UNDEFINED if EL3 is implemented and using AArch32 in all Secure privileged modes other than Monitor mode.

An indirect write to VDISR made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR occurring in program order after the ESB instruction.

If EL2 is not implemented, then VDISR is RES0 from Monitor mode when SCR.NS == 1.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.7 Generic Timer registers

This section lists the Generic Timer registers in AArch32.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

G8.7.1 CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Configurations

AArch32 System register CNTFRQ[31:0] is architecturally mapped to AArch64 System register CNTFRQ_EL0[31:0].

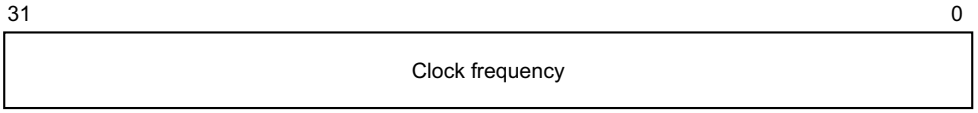
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:



Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTFRQ

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1110	0b0000	0b000

```
if PSTATE.EL == EL0 then

G8.7.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

Configurations

AArch32 System register CNTHCTL[31:0] is architecturally mapped to AArch64 System register CNTHCTL_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

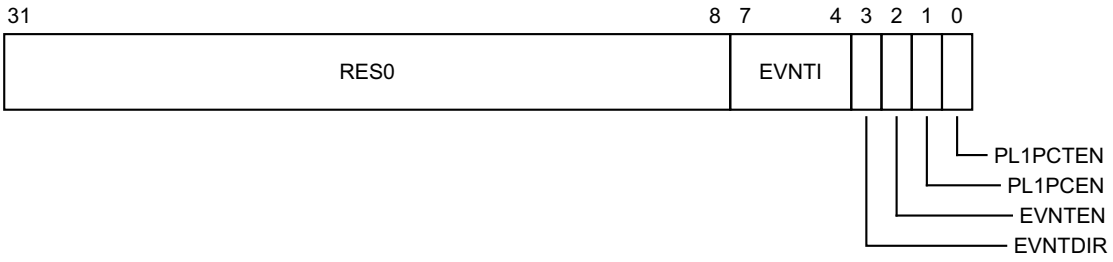
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHCTL is a 32-bit register.

Field descriptions

The CNTHCTL bit assignments are:



Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register CNTPCT is the trigger for the event stream generated from that counter, when that stream is enabled.

This field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the counter register CNTPCT trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

`0b0` A 0 to 1 transition of the trigger bit triggers an event.

`0b1` A 1 to 0 transition of the trigger bit triggers an event.

This field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register CNTPCT:

`0b0` Disables the event stream.

`0b1` Enables the event stream.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PL1PCEN, bit [1]

Traps Non-secure EL0 and EL1 accesses to the physical timer registers to Hyp mode.

0b0 Non-secure EL0 and EL1 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are trapped to Hyp mode, unless the it is trapped by CNTKCTL.PL0PTEN.

0b1 This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.

PL1PCTEN, bit [0]

Traps Non-secure EL0 and EL1 accesses to the physical counter register to Hyp mode.

0b0 Non-secure EL0 and EL1 accesses to the CNTPCT are trapped to Hyp mode, unless it is trapped by CNTKCTL.PL0PCTEN.

0b1 This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHCTL

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b100	0b1110	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;

G8.7.3 CNTHP_CTL, Counter-timer Hyp Physical Timer Control register

The CNTHP_CTL characteristics are:

Purpose

Control register for the Hyp mode physical timer.

Configurations

AArch32 System register CNTHP_CTL[31:0] is architecturally mapped to AArch64 System register CNTHP_CTL_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

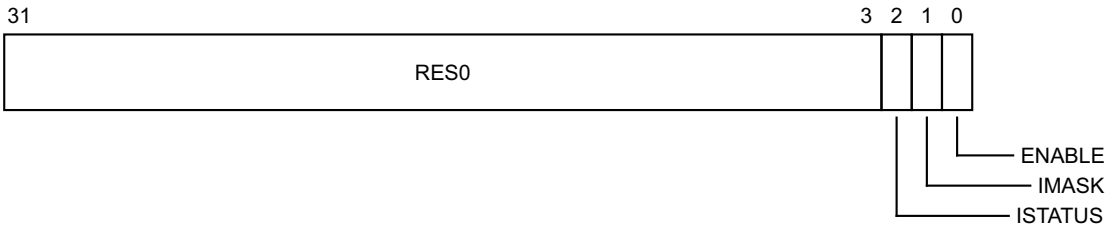
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CTL is a 32-bit register.

Field descriptions

The CNTHP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

In a system where the PE resets into EL2 or EL3, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHP_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

In a system where the PE resets into EL2 or EL3, this field resets to `0`.

Accessing the CNTHP_CTL

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b100	0b1110	0b0010	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    return CNTHP_CTL;
elsif PSTATE.EL == EL3 then

G8.7.4 CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register

The CNTHP_CVAL characteristics are:

Purpose

Holds the compare value for the Hyp mode physical timer.

Configurations

AArch32 System register CNTHP_CVAL[63:0] is architecturally mapped to AArch64 System register CNTHP_CVAL_EL2[63:0].

If EL2 is not implemented, this register is RES0 from EL3.

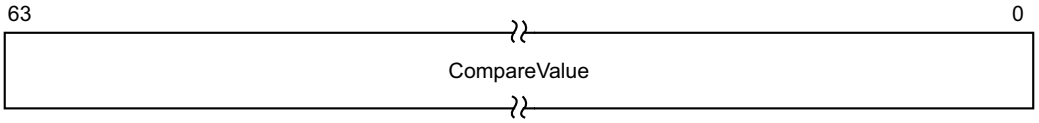
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CVAL is a 64-bit register.

Field descriptions

The CNTHP_CVAL bit assignments are:



CompareValue, bits [63:0]

Holds the EL2 physical timer CompareValue.

When CNTHP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHP_CTL.ISTATUS is set to 1.
- If CNTHP_CTL.IMASK is 0, an interrupt is generated.

When CNTHP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHP_CVAL

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.5 CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register

The CNTHP_TVAL characteristics are:

Purpose

Holds the timer value for the Hyp mode physical timer.

Configurations

AArch32 System register CNTHP_TVAL[31:0] is architecturally mapped to AArch64 System register CNTHP_TVAL_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

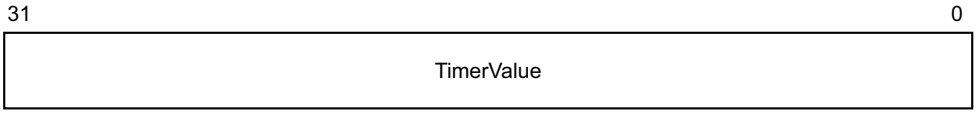
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_TVAL is a 32-bit register.

Field descriptions

The CNTHP_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHP_CTL.ENABLE is 1, the value returned is (CNTHP_CVAL - CNTPCT).

On a write of this register, CNTHP_CVAL is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CNTHP_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHP_CTL.ISTATUS is set to 1.
- If CNTHP_CTL.IMASK is 0, an interrupt is generated.

When CNTHP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHP_TVAL

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.6 CNTHPS_CTL, Counter-timer Secure Physical Timer Control Register (EL2)

The CNTHPS_CTL characteristics are:

Purpose

Provides AArch32 access to the Secure EL2 physical timer.

Note

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

Configurations

AArch32 System register CNTHPS_CTL[31:0] is architecturally mapped to AArch64 System register CNTHPS_CTL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_CTL are UNDEFINED.

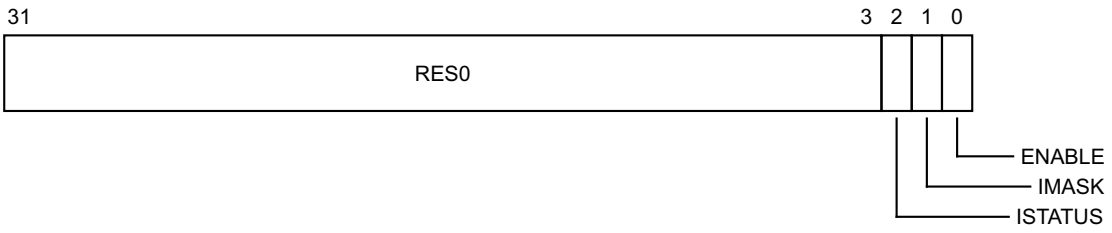
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHPS_CTL is a 32-bit register.

Field descriptions

The CNTHPS_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the CNTHPS_CTL.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the CNTHPS_CTL.ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0b0 Timer disabled.

0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHPS_TVAL_EL2 continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHPS_CTL

This register is accessed using the encoding for CNTP_CTL.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2

G8.7.7 CNTHPS_CVAL, Counter-timer Secure Physical Timer CompareValue Register (EL2)

The CNTHPS_CVAL characteristics are:

Purpose

Provides AArch32 access to the compare value for the Secure EL2 physical timer.

Note

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

Configurations

AArch32 System register CNTHPS_CVAL[63:0] is architecturally mapped to AArch64 System register CNTHPS_CVAL_EL2[63:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_CVAL are UNDEFINED.

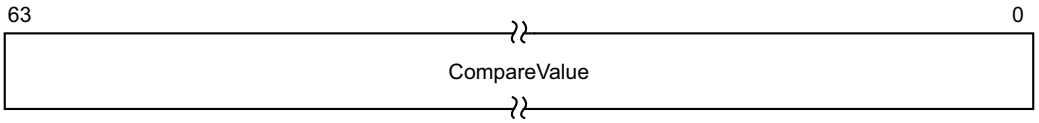
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHPS_CVAL is a 64-bit register.

Field descriptions

The CNTHPS_CVAL bit assignments are:



CompareValue, bits [63:0]

Holds the EL2 physical timer CompareValue.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHPS_CVAL

This register is accessed using the encoding for CNTP_CVAL.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.8 CNTHPS_TVAL, Counter-timer Secure Physical Timer TimerValue Register (EL2)

The CNTHPS_TVAL characteristics are:

Purpose

Provides AArch32 access to the timer value for the Secure EL2 physical timer.

Note

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

Configurations

AArch32 System register CNTHPS_TVAL[31:0] is architecturally mapped to AArch64 System register CNTHPS_TVAL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHPS_TVAL are UNDEFINED.

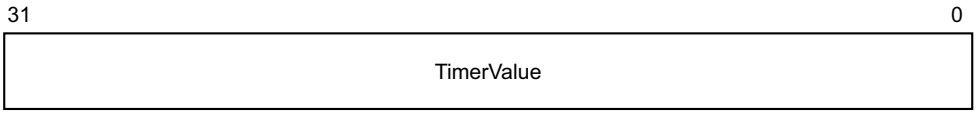
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHPS_TVAL is a 32-bit register.

Field descriptions

The CNTHPS_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHPS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHPS_CTL_EL2.ENABLE is 1, the value returned is (CNTHPS_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHPS_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHPS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTHPS_TVAL

This register is accessed using the encoding for CNTP_TVAL.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.9 CNTHV_CTL, Counter-timer Virtual Timer Control register (EL2)

The CNTHV_CTL characteristics are:

Purpose

Provides AArch32 access to the control register for the EL2 virtual timer.

Note

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.{E2H, TGE} is {1, 1}.

Configurations

AArch32 System register CNTHV_CTL[31:0] is architecturally mapped to AArch64 System register CNTHV_CTL_EL2[31:0].

This register is present only when ARMv8.1-VHE is implemented. Otherwise, direct accesses to CNTHV_CTL are UNDEFINED.

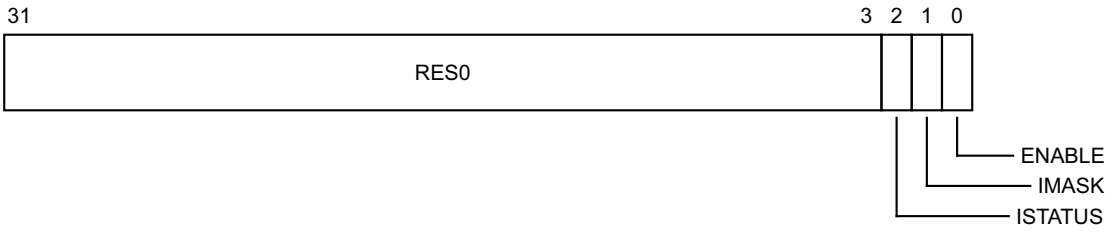
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHV_CTL is a 32-bit register.

Field descriptions

The CNTHV_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0b0 Timer disabled.

0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHV_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

Accessing the CNTHV_CTL

This register is accessed using the encoding for CNTV_CTL.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.7.10 CNTHV_CVAL, Counter-timer Virtual Timer CompareValue register (EL2)

The CNTHV_CVAL characteristics are:

Purpose

Provides AArch32 access to the compare value for the EL2 virtual timer.

Note

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.{E2H, TGE} is {1, 1}.

Configurations

AArch32 System register CNTHV_CVAL[63:0] is architecturally mapped to AArch64 System register CNTHV_CVAL_EL2[63:0].

This register is present only when ARMv8.1-VHE is implemented. Otherwise, direct accesses to CNTHV_CVAL are UNDEFINED.

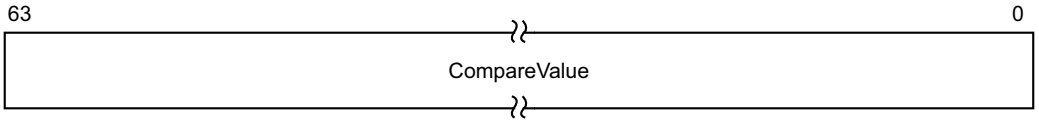
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHV_CVAL is a 64-bit register.

Field descriptions

The CNTHV_CVAL bit assignments are:



CompareValue, bits [63:0]

Holds the EL2 virtual timer CompareValue.

When CNTHV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTHV_CTL.ISTATUS is set to 1.
- If CNTHV_CTL.IMASK is 0, an interrupt is generated.

When CNTHV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

Accessing the CNTHV_CVAL

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.11 CNTHV_TVAL, Counter-timer Virtual Timer TimerValue register (EL2)

The CNTHV_TVAL characteristics are:

Purpose

Provides AArch32 access to the timer value for the EL2 virtual timer.

Note

The EL2 virtual timer is implemented by ARMv8.1-VHE. It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of HCR_EL2.{E2H, TGE} is {1, 1}.

Configurations

AArch32 System register CNTHV_TVAL[31:0] is architecturally mapped to AArch64 System register CNTHV_TVAL_EL2[31:0].

This register is present only when ARMv8.1-VHE is implemented. Otherwise, direct accesses to CNTHV_TVAL are UNDEFINED.

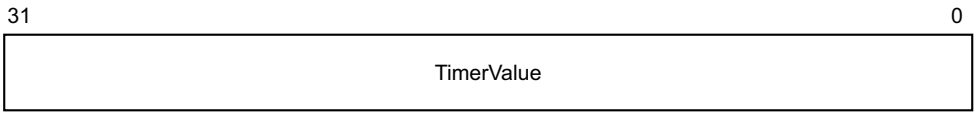
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHV_TVAL is a 32-bit register.

Field descriptions

The CNTHV_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHV_CTL.ENABLE is 1, the value returned is (CNTHV_CVAL - CNTVCT).

On a write of this register, CNTHV_CVAL is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CNTHV_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHV_CTL.ISTATUS is set to 1.
- If CNTHV_CTL.IMASK is 0, an interrupt is generated.

When CNTHV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

Accessing the CNTHV_TVAL

This register is accessed using the encoding for CNTV_TVAL.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.12 CNTHVS_CTL, Counter-timer Secure Virtual Timer Control Register (EL2)

The CNTHVS_CTL characteristics are:

Purpose

Provides AArch32 access to the Secure EL2 virtual timer.

Note

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

Configurations

AArch32 System register CNTHVS_CTL[31:0] is architecturally mapped to AArch64 System register CNTHVS_CTL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_CTL are UNDEFINED.

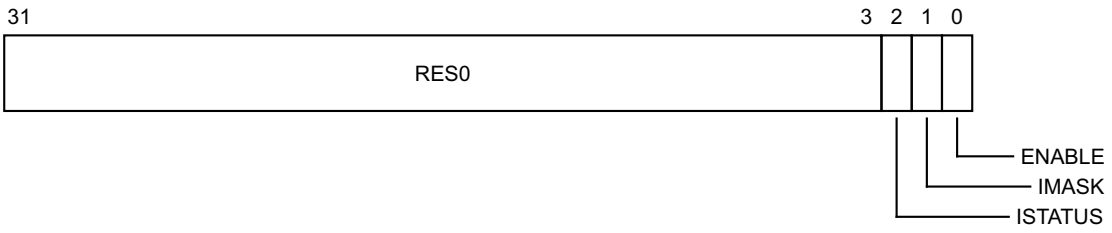
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHVS_CTL is a 32-bit register.

Field descriptions

The CNTHVS_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0b0 Timer disabled.

0b1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHVS_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

Accessing the CNTHVS_CTL

This register is accessed using the encoding for CNTV_CTL.

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.7.14 CNTHVS_TVAL, Counter-timer Secure Virtual Timer TimerValue Register (EL2)

The CNTHVS_TVAL characteristics are:

Purpose

Provides AArch32 access to the timer value for the Secure EL2 virtual timer.

Note

The Secure EL2 timer is implemented by ARMv8.4-SecEL2. It is only accessible from AArch32 state when EL2 is using AArch64 and the value of SCR_EL3.{EEL2, NS} is {1, 0}.

Configurations

AArch32 System register CNTHVS_TVAL[31:0] is architecturally mapped to AArch64 System register CNTHVS_TVAL_EL2[31:0].

This register is present only when ARMv8.4-SecEL2 is implemented. Otherwise, direct accesses to CNTHVS_TVAL are UNDEFINED.

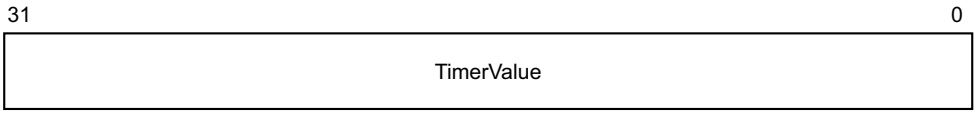
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHVS_TVAL is a 32-bit register.

Field descriptions

The CNTHVS_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If CNTHVS_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHVS_CTL.ENABLE is 1, the value returned is (CNTHVS_CVAL - CNTVCT).

On a write of this register, CNTHVS_CVAL is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHVS_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CNTHVS_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHVS_CTL.ISTATUS is set to 1.
- If CNTHVS_CTL.IMASK is 0, an interrupt is generated.

When CNTHVS_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

Accessing the CNTHVS_TVAL

This register is accessed using the encoding for CNTV_TVAL.

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.15 CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

Purpose

Controls the generation of an event stream from the virtual counter, and access from EL0 modes to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

Configurations

AArch32 System register CNTKCTL[31:0] is architecturally mapped to AArch64 System register CNTKCTL_EL1[31:0].

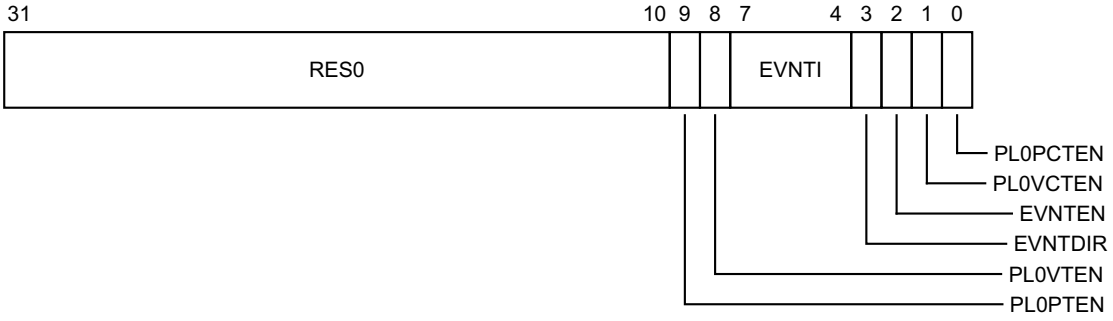
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTKCTL is a 32-bit register.

Field descriptions

The CNTKCTL bit assignments are:



Bits [31:10]

Reserved, RES0.

PL0PTEN, bit [9]

Traps PL0 accesses to the physical timer registers to Undefined mode.

`0b0` PL0 accesses to the CNTP_CTL, CNTP_CVAL, and CNTP_TVAL registers are trapped to Undefined mode.

`0b1` This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

PL0VTEN, bit [8]

Traps PL0 accesses to the virtual timer registers to Undefined mode.

`0b0` PL0 accesses to the CNTV_CTL, CNTV_CVAL, and CNTV_TVAL registers are trapped to Undefined mode.

`0b1` This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register CNTVCT is the trigger for the event stream generated from that counter, when that stream is enabled.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EVNTDIR, bit [3]

Controls which transition of the counter register CNTVCT trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0b0 A 0 to 1 transition of the trigger bit triggers an event.

0b1 A 1 to 0 transition of the trigger bit triggers an event.

This field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register CNTVCT:

0b0 Disables the event stream.

0b1 Enables the event stream.

This field resets to an architecturally UNKNOWN value.

PL0VCTEN, bit [1]

Traps PL0 accesses to the frequency register and virtual counter register to Undefined mode.

0b0 PL0 accesses to the CNTVCT are trapped to Undefined mode.

PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0PCTEN is also 0.

0b1 This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

PL0PCTEN, bit [0]

Traps PL0 accesses to the frequency register and physical counter register to Undefined mode.

0b0 PL0 accesses to the CNTPCT are trapped to Undefined mode.

PL0 accesses to the CNTFRQ register are trapped to Undefined mode, if CNTKCTL.PL0VCTEN is also 0.

0b1 This control does not cause any instructions to be trapped.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTKCTL

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1110	0b0001	0b000

G8.7.16 CNTP_CTL, Counter-timer Physical Timer Control register

The CNTP_CTL characteristics are:

Purpose

Control register for the EL1 physical timer.

Configurations

AArch32 System register CNTP_CTL[31:0] is architecturally mapped to AArch64 System register CNTP_CTL_EL0[31:0].

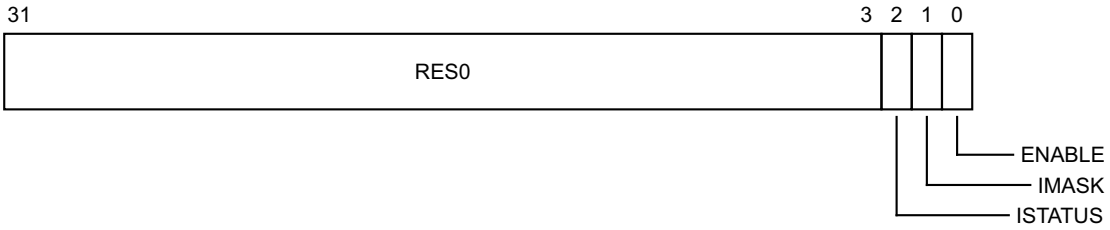
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to `0`.

Accessing the CNTP_CTL

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1110	0b0010	0b001

```

G8.7.17 CNTP_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

Configurations

AArch32 System register CNTP_CVAL[63:0] is architecturally mapped to AArch64 System register CNTP_CVAL_EL0[63:0].

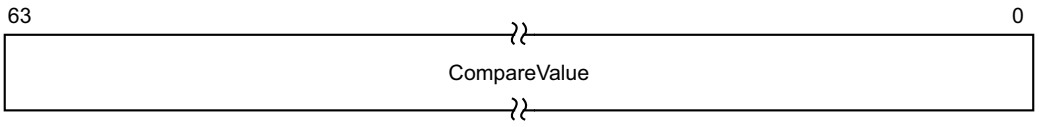
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

The CNTP_CVAL bit assignments are:



CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- If CNTP_CTL.IMASK is 0, an interrupt is generated.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_CVAL

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.18 CNTP_TVAL, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Configurations

AArch32 System register CNTP_TVAL[31:0] is architecturally mapped to AArch64 System register CNTP_TVAL_EL0[31:0].

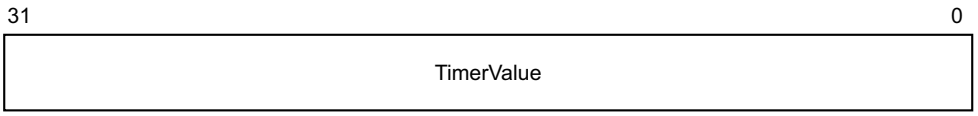
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL.ENABLE is 1, the value returned is (CNTP_CVAL - CNTPCT).

On a write of this register, CNTP_CVAL is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CNTP_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- If CNTP_CTL.IMASK is 0, an interrupt is generated.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_TVAL

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.20 CNTV_CTL, Counter-timer Virtual Timer Control register

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

Configurations

AArch32 System register CNTV_CTL[31:0] is architecturally mapped to AArch64 System register CNTV_CTL_EL0[31:0].

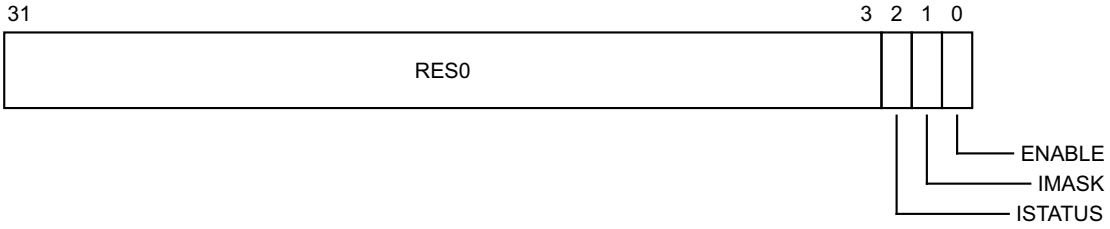
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to `0`.

Accessing the CNTV_CTL

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

coproc	opc1	CRn	CRm	opc2
0b1111	0b000	0b1110	0b0011	0b001

G8.7.21 CNTV_CVAL, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL characteristics are:

Purpose

Holds the compare value for the virtual timer.

Configurations

AArch32 System register CNTV_CVAL[63:0] is architecturally mapped to AArch64 System register CNTV_CVAL_EL0[63:0].

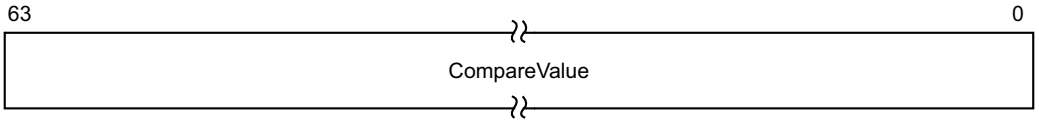
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:



CompareValue, bits [63:0]

Holds the EL1 virtual timer CompareValue.

When CNTV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- If CNTV_CTL.IMASK is 0, an interrupt is generated.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_CVAL

Accesses to this register use the following encodings in the System instruction encoding space:

G8.7.22 CNTV_TVAL, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

Configurations

AArch32 System register CNTV_TVAL[31:0] is architecturally mapped to AArch64 System register CNTV_TVAL_EL0[31:0].

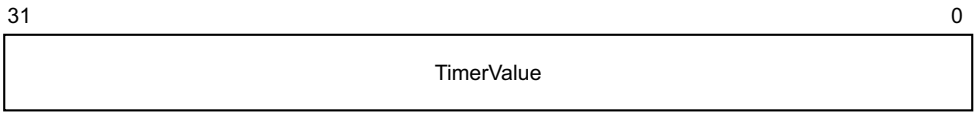
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the virtual timer.

On a read of this register:

- If CNTV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL.ENABLE is 1, the value returned is (CNTV_CVAL - CNTVCT).

On a write of this register, CNTV_CVAL is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CNTP_CVAL) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- If CNTV_CTL.IMASK is 0, an interrupt is generated.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_TVAL

Accesses to this register use the following encodings in the System instruction encoding space:

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

G8.7.23 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in CNTPCT minus the virtual offset visible in CNTVOFF.

Configurations

AArch32 System register CNTVCT[63:0] is architecturally mapped to AArch64 System register CNTVCT_EL0[63:0].

The value of this register is the same as the value of CNTPCT in the following conditions:

- When EL2 is not implemented.
- When EL2 is implemented and is using AArch64, HCR_EL2.{E2H, TGE} is {1, 1}, and this register is read from Non-secure EL0.

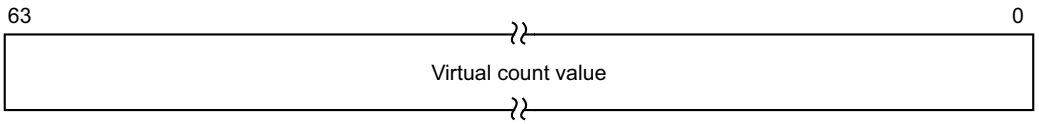
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:



Bits [63:0]

Virtual count value.

Accessing the CNTVCT

Accesses to this register use the following encodings in the System instruction encoding space:

MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

coproc	CRm	opc1
0b1111	0b1110	0b0001

```
if PSTATE.EL == EL0 then

G8.7.24 CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

Purpose

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT and the virtual count value visible in CNTVCT.

Configurations

AArch32 System register CNTVOFF[63:0] is architecturally mapped to AArch64 System register CNTVOFF_EL2[63:0].

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

Note

When EL2 is implemented and is using AArch64, if HCR_EL2.{E2H, TGE} is {1, 1}, the virtual counter uses a fixed virtual offset of zero when CNTVCT is read from Non-secure EL0.

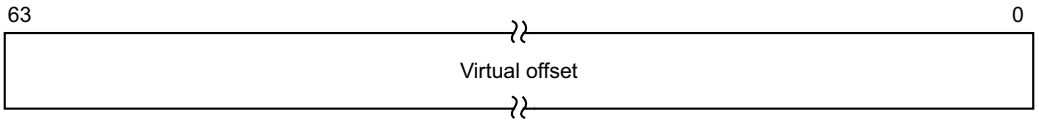
When EL2 is implemented and can use AArch32, on a reset into an Exception level that is using AArch32 this register resets to an IMPLEMENTATION DEFINED value that might be UNKNOWN.

Attributes

CNTVOFF is a 64-bit register.

Field descriptions

The CNTVOFF bit assignments are:



Bits [63:0]

Virtual offset.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTVOFF

Accesses to this register use the following encodings in the System instruction encoding space:

MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Part H
External Debug

Chapter H1
About External Debug

This chapter gives an overview of Armv8 external debug, and specifies the required debug authentication. It contains the following sections:

- *Introduction to external debug* on page H1-6700.
- *External debug* on page H1-6701.
- *Required debug authentication* on page H1-6702.

Note

For information about self-hosted debug, see Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H1.1 Introduction to external debug

Armv8 supports both:

Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger that accesses the chip through a Debug Access Port.

External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the Arm architecture defines required features that are called *external debug features*.

Note

An external debugger has a potentially high level of control over and visibility into the PE. The system sets this level using debug authentication. See *Required debug authentication* on page H1-6702.

If the debug authentication level is set too low, agents may be able to bypass elements of the security and privilege models. This includes both off-chip agents and on-chip agents such as unprivileged or Non-secure software.

H1.1.1 Definition and constraints of a debugger in the context of external debug

When the description of external debug in this Part of the manual describes a *debugger* as controlling external debug this debugger might be a second on-chip PE or an off-chip device such as a JTAG debugger using a Debug Access Port (DAP).

If a Debug Access Port is implemented:

- When debug is prohibited at the Debug Access Port, the port must not generate accesses to the external debug interface of the PE.
- When Secure debug is prohibited at the Debug Access Port, the port must not generate Secure accesses to the external debug interface of the PE.
- When Secure accesses are allowed at the Debug Access Port, the port must be able to generate Secure accesses.

If ARMv8.4-Debug is not implemented, accesses to the PE are controlled by the external authentication interface functions, `ExternalInvasiveDebugEnabled()`, `ExternalNoninvasiveDebugEnabled()`, `ExternalSecureNoninvasiveDebugEnabled()` and `ExternalSecureInvasiveDebugEnabled()`. The external authentication interface functions override MDCR_EL3.{EPMAD, EDAD}.

If ARMv8.4-Trace is implemented, the bus master, which may be the Debug Access Port, controls the accesses it makes to the PE and MDCR_EL3.{EPMAD, EDAD} control Non-secure access to registers.

The Debug Access Port is not required to use the same authentication interface as the PE.

Arm recommends the following authentication interface:

- When `ExternalSecureInvasiveDebugEnabled()`== FALSE at the PE, Secure debug is disabled at the DAP.
- When `ExternalInvasiveDebugEnabled()`== FALSE at the PE, all debug is prohibited at the DAP.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H1.2 External debug

Debug events allow an external debugger to halt the PE. Armv8 provides the following debug events:

- *Halting Step debug events* on page H3-6746:
  - The debugger can use this resource to make the PE step through code one line at a time.
- *Halt Instruction debug event* on page H3-6756:
  - This might occur when software executes the Halting breakpoint instruction, `HLT`.
- *Exception Catch debug event* on page H3-6757:
  - This can be programmed to occur on all entries to a given Exception level.
- *External Debug Request debug event* on page H3-6761:
  - An embedded cross-trigger can signal this debug event.
- *OS Unlock Catch debug event* on page H3-6762:
  - This might occur when the state of the OS Lock changes from locked to unlocked.
- *Reset Catch debug events* on page H3-6763:
  - This might occur when the PE exits reset state.
- *Software Access debug event* on page H3-6764:
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Breakpoints and watchpoints can also halt the PE.

When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register,* ITR, passes instructions to the PE to execute in Debug state:
  - The ITR contains a single register, EDITR, and associated flow-control flags.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

Chapter H2 *Debug State* describes Debug state in more detail.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H1.3 Required debug authentication

Any implementation must provide the debug authentication defined in this section, that controls:

- Whether the PE can halt.
- Whether non-invasive debug is permitted.
- Some legacy aspects of the AArch32 self-hosted debug model.

The pseudocode functions shown in Table H1-1, and the conditions that follow that table, define the architectural requirements for debug authentication.

Table H1-1 Debug authentication functions

Pseudocode function	Description
`ExternalSecureNoninvasiveDebugEnabled()`	Returns TRUE if Secure non-invasive debug is enabled.
`AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()`	Returns TRUE if Secure invasive self-hosted debug is enabled in AArch32 state.
`ExternalSecureInvasiveDebugEnabled()`	Returns TRUE if Secure invasive debug is enabled.
`ExternalNoninvasiveDebugEnabled()`	Returns TRUE if Non-secure non-invasive debug is enabled.
`ExternalInvasiveDebugEnabled()`	Returns TRUE if Non-secure invasive debug is enabled.

The following conditions always apply:

- If `ExternalInvasiveDebugEnabled()` is FALSE then `ExternalSecureInvasiveDebugEnabled()` is FALSE.
- If `ExternalNoninvasiveDebugEnabled()` is FALSE then `ExternalSecureNoninvasiveDebugEnabled()` is FALSE.
- If `ExternalInvasiveDebugEnabled()` is TRUE then `ExternalNoninvasiveDebugEnabled()` is TRUE.
- If `ExternalSecureInvasiveDebugEnabled()` is TRUE then `ExternalSecureNoninvasiveDebugEnabled()` is TRUE.

If ARMv8.4-Debug is implemented:

- `ExternalNoninvasiveDebugEnabled()` always returns TRUE.
- `ExternalSecureNoninvasiveDebugEnabled()`returns the same as `ExternalSecureInvasiveDebugEnabled()`.

Arm recommends the use of the interface described in *Recommended authentication interface* on page K2-7653 to provide this debug authentication. The pseudocode functions in Chapter J1 *Armv8 Pseudocode*, that are linked to by the entries in the *Pseudocode function* column of Table H1-1, assume that this interface is implemented.

Chapter H2
Debug State

This chapter describes Debug state. It contains the following sections:

- *About Debug state* on page H2-6704.
- *Halting the PE on debug events* on page H2-6705.
- *Entering Debug state* on page H2-6711.
- *Behavior in Debug state* on page H2-6714.
- *Exiting Debug state* on page H2-6740.

Note

Table K14-1 on page K14-7810 disambiguates the general register references used in this chapter.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register,* ITR, passes instructions to the PE to execute in Debug state.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.2 Halting the PE on debug events

For details of debug events, see *Introduction to Halting debug events* on page H3-6744 and *Breakpoint and Watchpoint debug events* on page H2-6706.

On a debug event, the PE must do one of the following:

- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:

- Whether halting is allowed by the current state of the debug authentication interface. See *Halting allowed and halting prohibited*.
- The type of debug event and the programming of the debug control registers.
  - See *Halting debug events* for all Halting debug events.
  - See *Breakpoint and Watchpoint debug events* on page H2-6706 for Breakpoint and Watchpoint debug events.

See also *Other debug exceptions* on page H2-6706.

This means that behavior can be CONSTRAINED UNPREDICTABLE if the conditions change. See *Synchronization and Halting debug events* on page H3-6765.

Summary of debug events and possible outcomes on page H3-6744 summarizes the possible outcomes of each type of debug event.

H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

- Halting is always prohibited in Debug state.
- Halting is always prohibited when `DoubleLockStatus()` == TRUE.
  - This means that ARMv8.0-DoubleLock is implemented and OS Double lock is locked.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
  - The PE is in Non-secure state and `ExternalInvasiveDebugEnabled()` == FALSE.
  - The PE is in Secure state and `ExternalSecureInvasiveDebugEnabled()` == FALSE.

  Note

  See Appendix K2 *Recommended External Debug Interface* for more information on these functions.
- Otherwise, halting is allowed.

For more information see:

- *Pseudocode description of Halting on debug events* on page H2-6710
- *Required debug authentication* on page H1-6702.

H2.2.2 Halting debug events

The Halting debug events are described in Chapter H3 *Halting Debug Events*.

When a Halting debug event is generated, it causes entry to Debug state if all of:

- Halting is allowed. See *Halting allowed and halting prohibited*.
- The Halting debug event is one of:
  - A Halt Instruction debug event and EDSCR.HDE == 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— A Software Access debug event and OSLSR_EL1.OSLK == 0, meaning that the OS Lock is unlocked.
— Neither a Halt Instruction debug event nor a Software Access debug event.

Note

— A Halt Instruction debug event is the only Halting debug event that relies on EDSCR.HDE == 1.
— Halting on Breakpoint and Watchpoint debug events is also controlled by EDSCR.HDE. See *Breakpoint and Watchpoint debug events*.
— EDSCR.HDE can be written by software when the OS Lock is locked. Privileged code can use MDCR_EL3.TDOSA and HDCR.TDOSA to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, the instruction that generated the Halting debug event is treated as UNDEFINED.
- If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.

In all other cases the Halting debug event is pended, see *Pending Halting debug events* on page H3-6765.

Summary of actions from debug events on page H2-6709 summarizes the possible outcome for each type of Debug event.

Note

Halting debug events never generate debug exceptions.

H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug is enabled, that is EDSCR.HDE == 1.
- Halting is allowed. See *Halting allowed and halting prohibited* on page H2-6705.
- The OS Lock is unlocked, that is OSLSR.OSLK == 0.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

MDSCR_EL1.MDE or DBGDSCRext.MDBGen is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

Note

EDSCR.HDE is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting debug mode in Non-secure state does not affect the Exception model in Secure state.

See Chapter D2 *AArch64 Self-hosted Debug*, Chapter G2 *AArch32 Self-hosted Debug*, and the Note in *Other debug exceptions*.

H2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The behavior of these events is unchanged when Halting debug mode is enabled, that is when EDSCR.HDE == 1. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.

H2.2.5 Debug state entry and debug event prioritization

The following are synchronous debug events:

- Breakpoint debug event.
- Watchpoint debug event.
- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous debug events are treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, if halting is allowed, the synchronous debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

Note

- Reset Catch and Exception Catch debug events might be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the reset or asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.
- The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events these are taken first.

If halting is prohibited then Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously. OS Unlock Catch debug events are always pended and taken asynchronously. See *Pending Halting debug events* on page H3-6765.

The architecture does not define when asynchronous debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED. See *Synchronization and Halting debug events* on page H3-6765.

The following list shows how the synchronous debug events are prioritized, with 1being the highest priority.

Note

The priority numbering is the same as the numbering for AArch64 synchronous exception priorities listed in *Synchronous exception types, routing and priorities* on page D1-2307, and in particular *Prioritization and recognition of interrupts* on page D1-2324. This numbering correlates with the equivalent AArch32 list in *Exception prioritization for exceptions taken to AArch32 state* on page G1-5504.

The priority for synchronous debug events is as follows:

1 Reset Catch debug event. See *Reset Catch debug events* on page H3-6763.

This debug event has a higher priority than the synchronous exceptions listed in *Synchronous exception types, routing and priorities* on page D1-2307.

2 Exception Catch debug event. See *Exception Catch debug event* on page H3-6757.

This debug event can be assigned one of two priorities. When it has a priority of 2, it has a higher priority than the synchronous exceptions listed in the Exception model. See *Exception Catch debug event* on page H3-6757.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

3	Halting Step debug event. See *Halting Step debug events* on page H3-6746. This debug event has a higher priority than the synchronous exceptions listed in the Exception model.
4	These events are not debug events.
5	Exception Catch debug event. See *Exception Catch debug event* on page H3-6757. This debug event can be assigned one of two priorities, 0 or 5. See *Exception Catch debug event* on page H3-6757.
6 - 7	These events are not debug events.
8	Breakpoint exception or debug event or Address Matching Vector Catch exception. See *Breakpoint exceptions* on page D2-2413, and *Vector Catch exceptions* on page G2-5667. These two debug events have the same priority.
9 - 10	These events are not debug events.
11	Halt Instruction debug event. See *Halt Instruction debug event* on page H3-6756.
12 - 24	These events are not debug events.
25	Software Access debug event. See *Software Access debug event* on page H3-6764.
24 - 27	These events are not debug events.
28	Watchpoint exception or debug event. See *Watchpoint exceptions* on page D2-2431 for exceptions taken from AArch64 state, or *Watchpoint exceptions* on page G2-5653 for exceptions taken from AArch32 state.
29	This event is not a debug event.

For Reset Catch debug events and Halting Step debug events the priorities listed in this section only apply when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pended.

For more information on the prioritization of exceptions see:

- *Synchronous exception types, routing and priorities* on page D1-2307.
- *Prioritization and recognition of interrupts* on page D1-2324.
- *Exception prioritization for exceptions taken to AArch32 state* on page G1-5504. This section covers synchronous and asynchronous exceptions.

Breakpoint debug events and Vector Catch exception

An Address Matching Vector Catch exception has the same priority as a Breakpoint debug event. See *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2308.

The prioritization of these events is unchanged even if the breakpoint generates entry to Debug state instead of a Breakpoint exception. This means that if a single instruction generates both an Address Matching Vector Catch exception and a Breakpoint debug event, there is a CONSTRAINED UNPREDICTABLE choice of:

- The PE entering Debug state due to the Breakpoint debug event.
- A Vector Catch exception.

This only applies if all of the following are true:

- Halting debug is enabled.
- Halting is allowed.
- The OS Lock is unlocked.

An Exception Trapping Vector Catch exception must be generated immediately following the exception that generated it. This means that it does not appear in the priority table.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.2.6 Imprecise entry to Debug state

Entry to Debug state is normally precise, meaning that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state.

A debugger can write a value of 1 to EDRCR.CBRRQ to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is OPTIONAL and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit if either:

- External debugging is not enabled, meaning `ExternalInvasiveDebugEnabled()` == FALSE.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled()` == FALSE, and either:
  - EL3 is not implemented and the implemented Security state is Secure state.
  - EL3 is implemented.

Example H2-1 shows how entry to Debug state can be forced.

Example H2-1 Forcing entry to Debug state

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to EDRCR.CBRRQ. The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

H2.2.7 Summary of actions from debug events

Table H2-1 on page H2-6710 shows the Software and Halting debug events. In Table H2-1 on page H2-6710 the columns have the following meaning:

Debug event type

This means the type of debug event where:

Other software Means one of:

- *Software Step exceptions* on page D2-2446.
- *Breakpoint Instruction exceptions* on page D2-2411.
- *Vector Catch exceptions* on page D2-2445 for AArch64 state or *Vector Catch exceptions* on page G2-5667 for AArch32 state.

Other Halting Means one of the following:

- *Halting Step debug events* on page H3-6746.
- *External Debug Request debug event* on page H3-6761.
- *Reset Catch debug events* on page H3-6763.
- *OS Unlock Catch debug event* on page H3-6762.

Other debug events are referred to explicitly.

Authentication

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of one of the following pseudocode functions:

In Secure state `ExternalSecureInvasiveDebugEnabled()`.

In Non-secure state `ExternalInvasiveDebugEnabled()`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DLK This indicates whether ARMv8.0-DoubleLock is implemented and locked, `DoubleLockStatus()` == TRUE.

OSLK This is the value of OSLSR.OSLK. It indicates whether the OS Lock is locked.

HDE This is the value of EDSCR.HDE. It indicates whether Halting debug is enabled.

The letter X in Table H2-1 indicates that the value can be either 0 or 1.

Table H2-1 Debug authentication for external debug

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other software	X	X	X	X	Handled by the Exception model
Breakpoint or Watchpoint debug event	X	TRUE	X	X	Handled by the Exception model (ignored)
	X	FALSE	1	X	Handled by the Exception model (ignored)
	FALSE	FALSE	0	X	Handled by the Exception model
	TRUE	FALSE	0	0	Handled by the Exception model
	TRUE	FALSE	0	1	Entry to Debug state
Halt Instruction debug event	FALSE	X	X	X	undefined
	TRUE	TRUE	X	X	undefined
	TRUE	FALSE	X	0	undefined
	TRUE	FALSE	X	1	Entry to Debug state
Exception Catch debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	X	X	Entry to Debug state
Software Access debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	1	X	Ignored
	TRUE	FALSE	0	X	Entry to Debug state
Other Halting	FALSE	X	X	X	Debug event is pended
	TRUE	TRUE	X	X	Debug event is pended
	TRUE	FALSE	X	X	Entry to Debug state

H2.2.8 Pseudocode description of Halting on debug events

The `Halted()`, `Restarting()`, `HaltingAllowed()`, and `HaltOnBreakpointOrWatchpoint()` functions are described in the Armv8 pseudocode.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.3 Entering Debug state

On entry to Debug state, the preferred restart address and PSTATE are saved in DLR and DSPSR. The PE remains in the mode and security state from which it entered Debug state.

If EDRCR.CBRRQ has a value of 0, entry to Debug state is precise. If EDRCR.CBRRQ has a value of 1, then imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the address of the access that generated the Watchpoint debug event is recorded in EDWAR.

For more information see:

- *Determining the memory location that caused a Watchpoint exception* on page D2-2439 for a debug event taken from AArch64 state.
- *Determining the memory location that caused a Watchpoint exception* on page G2-5660 for a debug event taken from AArch32 state.

Other than the effect on PSTATE and EDSCR, entry to Debug state is not a *Context synchronization event*. The effects of entry to Debug state on PSTATE and EDSCR are synchronized.

H2.3.1 Entering Debug state from AArch32 state

When entering Debug state from AArch32 state, the PE remains in AArch32 state. In AArch32 Debug state the PE executes T32 instructions, regardless of the value of PSTATE.T before entering Debug state.

To allow the debugger to determine the state of the PE, the current Execution state for all four Exception levels can be read from EDSCR.RW, and the current Exception level can be read from EDSCR.EL.

The current endianness state, PSTATE.E, is unchanged on entry to Debug state.

Note

- If EL1 is using AArch32 state, the current endianness state can differ from that indicated by SCTLR.EE.
- If EL2 is using AArch32 state, the current endianness state can differ from that indicated by HSCTLR.EE.
- On entry to Debug state from AArch32 state, PSTATE.SS is copied to DSPSR.SS, even though the PE remains in AArch32 state.

See also *Effect of entering Debug state on PSTATE* on page H2-6713.

H2.3.2 Effect of Debug state entry on DLR and DSPSR

DLR is set to the preferred restart address for the debug event, that depends on the event type. The value of PSTATE is saved in DSPSR.

For entry to Debug state from AArch32 state, the values saved in DSPSR.IT are always correct for the preferred restart address.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event. It is CONSTRAINED UNPREDICTABLE whether DSPSR_EL0.BTYPE is set to the value of PSTATE.BTYPE or 0 for synchronous debug events other than the following debug events:

- A Halting Step debug event.
- A Breakpoint debug event.
- A Halt Instruction debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception, as described in Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.
- For Halt Instruction debug events DLR is set to the address of the `HLT` instruction and DSPSR.IT is correct for the `HLT` instruction.
- For Software Access debug events, DLR is set to the address of the accessing instruction and DSPSR.IT is correct for this instruction.
- For Halting Step debug events taken synchronously, DLR and DSPSR are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and PSTATE for, the instruction after the one that was stepped.
- For Exception Catch debug events:
  - If the debug event is generated on taking an exception to a trapped Exception level, the DLR is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. The DSPSR records the value of PSTATE after taking the exception. The Exception Catch occurs after the SPSR and the Link register are set, and the debugger can use these registers to determine where in the application program the exception occurred.

    Note

    Depending on the target Exception level and Execution state for the exception, the Link register is one of ELR_EL1, ELR_EL2, ELR_EL3, ELR_hyp, or LR (R14).

  - If the debug event is generated on an exception return to a trapped Exception level, the DLR is set to the target address of the exception return and the DSPSR records the value of PSTATE after the exception return.
- Reset Catch debug events taken synchronously behave like Exception Catch debug events.
- For Reset Catch debug events and Exception Catch debug events generated on reset to a trapped Exception level, the DLR is set to is set to the reset address and the DSPSR records the reset value of PSTATE.
- For pending Halting debug events and External Debug Request debug events, DLR is set to the address of the first instruction that must be executed on exit from Debug state and DSPSR.IT is correct for this instruction. See *Pending Halting debug events* on page H3-6765.

Normally DLR is aligned according to the instruction set state indicated in DSPSR. However, a debug event might be taken at a point where the PC is not aligned.

H2.3.3 Effect of Debug state entry on System registers, the Event register, and Exclusives monitors

Entering Debug state has no effect on System registers other than DLR and DSPSR. In particular, ESRs, FARs, and FSRs are not updated on entering Debug state. SCR is unchanged, even when entering Debug state from EL3.

Entering Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors.

Note

Entry to Debug state might set the Event Register or clear the Exclusives monitors, or both. However, this is not a requirement, and debuggers must not rely on any implementation specific behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the System registers, the Event register, and Exclusives monitors.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.3.4 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on PSTATE is described in *Entering Debug state* on page H2-6711 and *Entering Debug state from AArch32 state* on page H2-6711.

On entry to Debug state after PSTATE is saved in DSPSR:

- PSTATE.IL is cleared to 0.
- PSTATE.TCO is set to 1.
- PSTATE.BTYPE is set to 0.
- PSTATE.{IT, T, SS, D, A, I, F, SSBS} are set to UNKNOWN values

PSTATE.{N, Z, C, V, Q, GE, E, M, nRW, EL, SP, PAN, UAO, DIT} are unchanged.

For more information see *PSTATE in Debug state* on page H2-6714.

H2.3.5 Entering Debug state during loads and stores

The PE can enter Debug state during instructions that perform a sequence of memory accesses, as opposed to a single single-copy atomic access, because of a Watchpoint debug event. The effect of entering Debug state on such an instruction is the same as taking a Data Abort exception during such an instruction.

In addition, when executing in AArch64 state, the PE can enter Debug state during instructions that perform a sequence of memory accesses because of an External Debug Request debug event. The effect of entering Debug state on such an instruction is the same as taking an interrupt exception during such an instruction.

This applies to all memory types.

H2.3.6 Entering Debug state and Software Step

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with DSPSR.SS set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with DSPSR.SS set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with DSPSR.SS set to 0. This is because PSTATE.SS is set to 0 by taking the exception.
- If the PE is reset, PSTATE.SS is reset to 0. If the following debug events are enabled, the PE enters Debug state with DSPSR.SS set to 0:
  - Reset Catch debug event at the reset Exception level.
  - Exception Catch debug event at the reset Exception level.
  - Halting Step debug event.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and DSPSR.SS is set to 0.

H2.3.7 Pseudocode description of entering Debug state

The `DebugHalt` constants are described in *shared/debug/halting/DebugHalt* on page J1-7503 in the Armv8 pseudocode. The `UpdateEDSCRFields()` and `Halt()` functions are described in Chapter J1 *Armv8 Pseudocode*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, EDITR. The Execution state of the PE determines which instruction set is executed:

- If the PE is in AArch64 state it executes A64 instructions.
- If the PE is in AArch32 state it executes T32 instructions:
  - For a 32-bit T32 instruction, EDITR[15:0] specifies the first halfword and EDITR[31:16] specifies the second halfword.
  - For a 16-bit T32 instruction, EDITR[15:0] contains the instruction and EDITR[31:16] is ignored. All 16-bit T32 instructions are UNPREDICTABLE in Debug state.

The PE does not execute A32 instructions in Debug state.

Some instructions are available only in Debug state. See *Debug state operations, DCPS, DRPS, MRS, MSR* on page H2-6731. In Non-debug state these instructions are UNDEFINED.

The following sections describe behavior in Debug state:

- *PSTATE in Debug state*.
- *Executing instructions in Debug state* on page H2-6715.
- *Decode tables* on page H2-6726.
- *Security in Debug state* on page H2-6730.
- *Privilege in Debug state* on page H2-6731.
- *Debug state operations, DCPS, DRPS, MRS, MSR* on page H2-6731.
- *Exceptions in Debug state* on page H2-6734.
- *Accessing registers in Debug state* on page H2-6736.
- *Accessing memory in Debug state* on page H2-6739.

This section specifies the CONSTRAINED UNPREDICTABLE behaviors that apply in Debug state, but see *Changing the value of EDECR.SS when not in Debug state* on page H3-6753 for a change in Non-debug state that causes CONSTRAINED UNPREDICTABLE behavior.

H2.4.1 PSTATE in Debug state

PSTATE.{N, Z, C, V, Q, GE, IT, T, SS, D, A, I, F, SSBS} are all ignored in Debug state:

- There are no conditional instructions in Debug state.
- In AArch32 state, the PE only executes T32 instructions and PSTATE.IT is ignored.
- Asynchronous exceptions and debug events are ignored.
- Software step is inactive.

Instructions executed in Debug state indirectly read PSTATE.{UAO, PAN, IL, E, M, nRW, EL, SP} as they would in Non-debug state.

Note

PSTATE.DIT is not guaranteed to have any effect in Debug state.

In Debug state:

- PSTATE.PAN is set to 1 by:
  - A DCPS instruction to EL1 using AArch64 if SCTLR_EL1.SPAN == 0.
  - A DCPS instruction to EL2 using AArch64 if SCTLR_EL2.SPAN == 0.
- PSTATE.UAO is set to 0 by a DCPS instruction to AArch64 state.
- PSTATE.TCO is set to 1 by a DCPS instruction to AArch64 state.
- PSTATE can also be changed by taking exceptions in Debug state, and by the execution of DCPS and DRPS instructions.

When in Debug state, if ARMv8.0-SSBS is implemented, then hardware is permitted to load or store speculatively, regardless of the value of PSTATE.SSBS.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions or T32 instructions, depending on the current Execution state.

Each instruction falls into one of the following groups:

- Debug state instructions. These are instructions that are changed in Debug state. See *A64 instructions that are changed in Debug state* and *T32 instructions that are changed in Debug state* on page H2-6721.
- Instructions that are unchanged in Debug state. See *A64 instructions that are unchanged in Debug state* and *T32 instructions that are unchanged in Debug state* on page H2-6721.
- Instructions that are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state. See *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-6718 and *T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-6723.

All T32 instructions are treated as unconditional, regardless of PSTATE.IT. See *PSTATE in Debug state* on page H2-6714.

If EDSCR.SDD == 1 then an instruction executed in Non-secure state cannot cause entry into Secure state. See *Security in Debug state* on page H2-6730

Executing A64 instructions in Debug state

The following sections describe the behavior of the A64 instructions in Debug state:

- *A64 instructions that are changed in Debug state*.
- *A64 instructions that are unchanged in Debug state*.
- *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-6718.

A64 instructions that are changed in Debug state

The following A64 instructions are defined in Debug state, but are undefined in Non-debug state:

- `DCPS`.

  Note

  `DCPS` can be UNDEFINED in certain conditions in Debug state. See *DCPS<n>* on page H2-6731.

- `DRPS`.
- `MRS` (DLR_EL0), `MRS` (DSPSR_EL0), `MSR` (DLR_EL0), `MSR` (DSPSR_EL0)

For more information see *Debug state operations, DCPS, DRPS, MRS, MSR* on page H2-6731.

A64 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state:

Any instruction that is UNDEFINED in Non-debug state

This list of instructions excludes:

- Any instruction listed in *A64 instructions that are changed in Debug state*.
- Any instruction listed in *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-6718 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

This list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes PSTATE access instructions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

These instructions are:

- `MRS <special_reg>`, `MSR <special_reg>`.

  Note

  This does not include NZCV, DAIF, DAIFSet, DAIFClr, SPSel, and CurrentEL.

- `MRS <system_reg>`, `MSR <system_reg>`.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `FMOV` (between a general-purpose register and a half-precision register).
- `FMOV` (between a general-purpose register and a single-precision register).
- `FMOV` (between a general-purpose register and a double-precision register).
- `FMOV` (between a general-purpose register and a SIMD element).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `INS` (from a general-purpose register to a SIMD element).
- `UMOV` (from a SIMD element to a general-purpose register).

Barriers

These instructions are:

- `DMB`.
- `DSB`.
- `ESB`, when the RAS Extension is implemented.
- `ISB`.
- `PSB`, when the Statistical Profiling Extension is implemented.
- `SB`, when ARMv8.0-SB is implemented.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Unscaled (9-bit signed) immediate offset.
  - Immediate (9-bit signed) post-indexed.
  - Immediate (9-bit signed) pre-indexed.
  - Unprivileged (9-bit signed).
- Not literal.
- One of the following types:
  - (Single) register.
  - Exclusive.
  - Exclusive pair.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive pair.
- 32-bit and 64-bit target register variants.

These instructions are:

- `LDR`, `LDRB`, `LDRH`, `LDRSB`, `LDRSH`, `LDRSW` (immediate, not literal).
- `LDUR`, `LDURB`, `LDURH`, `LDURSB`, `LDURSH`, `LDURSW` (immediate).
- `LDTR`, `LDTRB`, `LDTRH`, `LDTRSB`, `LDTRSH`, `LDTRSW` (immediate).
- `LDAR`, `LDARB`, `LDARH`, `LDXR`, `LDXRB`, `LDXRH`, `LDAXR`, `LDAXRB`, `LDAXRH`.
- `LDXP`, `LDAXP`.
- `STR`, `STRB`, `STRH` (immediate).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- STUR, STURB, STURH (immediate).
- STTR,STTRB, STTRH (immediate).
- STLR, STLRB, STLRH, STXR, STXRB, STXRH, STLXR, STLXRB, STLXRH.
- STXP, STLXP.
- LDLAR, LDLARB, LDLARH - Armv8.1 instructions.
- STLLR, STLLRBB, STLLRH - Armv8.1 instructions.
- CAS, CASB, CASH, CASP - Armv8.1 instructions.
- SWP, SWPB, SWPH - Armv8.1 instructions.
- LDADD, LDADDB, LDADDH - Armv8.1 instructions.
- LDCLR, LDCLB, LDCLRH - Armv8.1 instructions.
- LDEOR, LDEORB, LDEORH - Armv8.1 instructions.
- LDSET, LDSETB, LDSETH - Armv8.1 instructions.
- LDSMAX, LDSMAXB, LDSMAXH - Armv8.1 instructions.
- LDSMIN, LDSMINB, LDSMINH - Armv8.1 instructions.
- LDUMAX, LDUMAXB, LDUMAXH - Armv8.1 instructions.
- LDUMIN, LDUMINB, LDUMINH - Armv8.1 instructions.
- STADD, STADDB, STADDH - Armv8.1 instructions.
- STCLR, STCLB, STCLRH - Armv8.1 instructions.
- STEOR, STEORB, STEORH - Armv8.1 instructions.
- STSET, STSETB, STSETH - Armv8.1 instructions.
- STSMAX, STSMAXB, STSMAXH - Armv8.1 instructions.
- STSMIN, STSMINB, STSMINH - Armv8.1 instructions.
- STUMAX, STUMAXB, STUMAXH - Armv8.1 instructions.
- STUMIN, STUMINB, STUMINH - Armv8.1 instructions.
- LDAPR, LDAPRB, LDAPRH - Armv8.3 instructions.
- LDAPURH, LDAPURSH, LDAPUR, LDAPURSW, LDAPURSB, LDAPURB - Armv8.4 instructions.
- STLUR, STLURH, STLURB - Armv8.4 instructions.

Move immediate to general-purpose register

These instructions are:

- MOVZ, MOVN, MOVK (immediate).
- MOV (between a general-purpose register and the stack pointer).

System instructions, Send Event, NOP, and Clear Exclusive

In this context, the System instructions are the Cache maintenance instructions, TLB maintenance instructions, and the Address translation instructions.

These instructions are:

- IC.
- DC.
- TLBI.
- AT.
- SEV, SEVL.
- NOP.
- CLREX.

Memory Tagging Extension Instructions

When ARMv8.5-MemTag is implemented, Loads and stores in Debug state follow the same rules for Tag Checking as Loads and stores when not in Debug state. For more information see Chapter D6 *Armv8.5 Memory Tagging Extension*.

The following instructions are unchanged in Debug state:

- ADDG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>
- SUBG <Xd|SP>, <Xn|SP>, #<uimm6>, #<uimm4>

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- STG <Xt>, [<Xn|SP>{, #<simm>}], signed offset.
- STZG <Xt>, [<Xn|SP>{, #<simm>}], signed offset.
- ST2G <Xt>, [<Xn|SP>{, #<simm>}], signed offset.
- STZ2G <Xt>, [<Xn|SP>{, #<simm>}], signed offset.
- LDG <Xt>, [<Xn|SP>{, #<simm>}]
- LDGM <Xt>, [<Xn|SP>]
- STGM <Xt>, [<Xn|SP>]
- STZGM <Xt>, [<Xn|SP>]
- STGP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]

A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state

This subsection describes all instruction not listed in either:

- *A64 instructions that are changed in Debug state* on page H2-6715.
- *A64 instructions that are unchanged in Debug state* on page H2-6715.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR_EL0 and DSPSR_EL0 to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for A64 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed. An example of this is CCMP.

Exception-generating instructions

These instructions are:

- SVC.
- HVC.
- SMC.
- BRK.
- HLT.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- SVC behaves as DCPS1.
- HVC behaves as DCPS2.
- SMC behaves as DCPS3.
- They generate the exception that the instruction would generate in Non-debug state. The exception is taken as described in *Exceptions in Debug state* on page H2-6734

Note

SMC must not generate a Secure Monitor Call exception from Non-secure state if EDSCR.SDD is set to 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Instructions that explicitly write to the PC (branches)

These instructions are:

- `B`, `B.cond`, `BL`, `BLR`, `BR`, `CBZ`, `CBNZ`, `RET`, `TBZ`, `TBNZ`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Exception return and related instructions

These instructions are:

- `ERET`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state without branching. They set DSPSR_EL0 and DLR_EL0 to UNKNOWN values, and either:
  - — Execute the DRPS operation instead of performing an exception return, using UNKNOWN SPSR values.
  - — Not change the Exception level.

Instructions that request entry to a low-power state

These instructions are:

- `WFE`, `WFI`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See *Configurable instruction enables and disables, and trap controls* on page D1-2326.
- A `WFE` instruction clears the Event register if it is set.

Note

This means that these instructions must not suspend execution.

Instructions that read the PC

These instructions are:

- `LDR` (literal), `LDRSW` (literal).
- `ADR`, `ADRP`.
- `PRFM` (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state, using an UNKNOWN value for the PC operand.

Instructions that explicitly modify **PSTATE, other than** `DCPS` **and** `DRPS`

These instructions are:

- `ADDS`, `SUBS`, `ADCS`, `SBCS`, `ANDS`, `BICS`, `CCMN`, `CCMP`.
- `FCMP`, `FCMPE`, `FCCMP`, `FCCMPE`.
- `MSR DAIFSet` (immediate), `MSR DAIFClr` (immediate), `MSR SPSel` (immediate).
- `MSR NZCV` (register), `MSR DAIF` (register), `MSR SPSel` (register).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When ARMv8.1-PAN is implemented, `MSR PAN` (immediate) and `MSR PAN` (register).
- When ARMv8.2-UAO is implemented, `MSR UAO` (immediate) and `MSR UAO` (register).
- When ARMv8.4-CondM is implemented, `CFINV`, `RMIF`, `SETF8`, `SETF16`.
- When ARMv8.4-DIT is implemented, `MSR DIT`.
- When ARMv8.5-CondM is implemented, `AXFLAG` and `XAFLAG`.
- When ARMv8.5-MemTag is implemented, `MSR TCO`.
- When ARMv8.5-RNG is implemented, `MRS RNDR` and `MRS RNDRRS`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- `CSEL`, `CSINC`, `CSINV`, `CSNEG`, `CCMN`, `CCMP`, `FCSEL`, `FCCMP`, `FCCMPE`.
- `ADC`, `ADCS`,`SBC`, `SBCS`.
- `CFINV`.
- `MRS NZCV`, `MRS DAIF`, `MRS SPSel`, `MRS CurrentEL`.
- When ARMv8.1-PAN is implemented, `MRS PAN`.
- When ARMv8.2-UAO is implemented, `MRS UAO`.
- When ARMv8.4-CondM is implemented, `CFINV`.
- When ARMv8.4-DIT is implemented, `MRS DIT`.
- When ARMv8.5-MemTag is implemented `MRS TCO`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state:
  - For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the Condition flag.
  - For the `MRS` instruction, they return an UNKNOWN value.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They have the same behavior as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state.

Executing T32 instructions in Debug state

The following sections describe the behavior of the T32 instructions in Debug state:

- *T32 instructions that are changed in Debug state* on page H2-6721.
- *T32 instructions that are unchanged in Debug state* on page H2-6721.
- *T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-6723.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T32 instructions that are changed in Debug state

The following T32 instructions are defined in Debug state, but are undefined in Non-debug state:

- `DCPS`

  Note

  `DCPS` can be UNDEFINED in certain conditions in Debug state. See *DCPS<n> on page H2-6731*.

- `MRC p15,3,<Rt>,c4,c5,0` (DSPSR).
- `MCR p15,3,<Rt>,c4,c5,0` (DSPSR).
- `MRC p15,3,<Rt>,c4,c5,1` (DLR).
- `MCR p15,3,<Rt>,c4,c5,1` (DLR).

In addition, `ERET` executes the DRPS operation in Debug state.

For more information see *Debug state operations, DCPS, DRPS, MRS, MSR on page H2-6731*.

T32 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state. Any T32 instruction that uses the PC or APSR.{N, Z, C, V} as the source or destination register is not included in the list. Moreover, the list only includes the 32-bit T32 encodings.

Any instruction that is UNDEFINED in Non-debug state

The list of instructions:

- Excludes any instruction listed in *T32 instructions that are changed in Debug state*.
- Excludes any instruction listed in *T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-6723 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

The list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes APSR and CPSR access instructions.
- Excludes instructions for accessing banked registers for the current mode.

These instructions are:

- `MRS <banked_reg>, MSR <banked_reg>.`

  Note

  This does not apply to cases which are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state in the current mode.

- `MRC, MCR.`

  Note

  This includes all allocated System registers in the (`coproc==0b111x`) encoding space other than an `MRC` move to APSR_nzcv.

- `MRS SPSR, MSR SPSR.`
- `VMRS <vfp_system_reg>, VMSR <vfp_system_reg>.`

  Note

  This includes all allocated Advanced SIMD and floating-point System registers, other than an a `VMRS` move to APSR_nzcv.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `VMOV` (between a general-purpose register and a single-precision register).
- `VMOV` (between a general-purpose register and a doubleword floating-point register).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `VMOV` (between a general-purpose register and a scalar).

Barriers These instructions are:

- `DMB`.
- `DSB`.
- `ESB`, when the RAS Extension is implemented.
- `ISB`.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Immediate (8-bit or 12-bit) offset.
  - Immediate (8-bit) post-indexed.
  - Immediate (8-bit) pre-indexed.
  - Unprivileged (8-bit).
- Not literal.
- One of the following types:
  - (Single) register.
  - Dual.
  - Exclusive.
  - Exclusive doubleword.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive doubleword.

These instructions are:

- `LDR.W, LDRB.W, LDRH.W, LDRD, LDRSB.W, LDRSH.W` (immediate, not literal).
- `LDRT, LDRBT, LDRHT, LDRSBT, LDRSHT` (immediate).
- `LDREX, LDREXB, LDREXH, LDA, LDAB, LDAH, LDAEX, LDAEXB, LDAEXH`.
- `LDREXD, LDAEXD`.
- `STR.W, STRB.W, STRH.W, STRD` (immediate).
- `STRT, STRBT, STRHT` (immediate).
- `STREX, STREXB, STREXH, STL, STLB, STLH, STLEX, STLEXB, STLEXH`.
- `STREXD, STLEXD`.

Move to general-purpose register

These instructions are:

- `MOVW`, `MOVT` (immediate).

System instructions, Send Event, `NOP`, and Clear Exclusive

The System instructions are Cache maintenance instructions, TLB maintenance instructions, and Address translation instructions. These are encoded in the (`coproc==0b1111`) System register encoding space.

These instructions are:

- ICIALLU, ICIALLUIS, ICIMVAU.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- DCCIMVAC, DCCISW, DCCMVAC, DCCMVAU, DCCSW, DCIMVAC, DCISW.
- TLBIALL, TLBIALLH, TLBIALLHIS, TLBIALLIS, TLBIALLNSNH, TLBIALLNSNHIS, TLBIASID, TLBIASIDIS, TLBIIPAS2, TLBIIPAS2IS, TLBIIPAS2L, TLBIIPAS2LIS, TLBIMVA, TLBIMVAA, TLBIMVAAIS, TLBIMVAAL, TLBIMVAALIS, TLBIMVAH, TLBIMVAHIS, TLBIMVAIS, TLBIMVAL, TLBIMVALH, TLBIMVALHIS, TLBIMVALIS.
- ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, ATS12NSOUW, ATS1CPR, ATS1CPW. ATS1CUR, ATS1CUW, ATS1HR, ATS1HW.
- BPIALL, BPIALLIS, BPIMVA.
- `SEV.W`, `SEVL.W`.
- `NOP.W`.
- `CLREX`.

T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state

This subsection describes all instruction not listed in either:

- *T32 instructions that are changed in Debug state* on page H2-6721.
- *T32 instructions that are unchanged in Debug state* on page H2-6721.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction generates an Undefined Instruction exception.
- The instruction executes as a `NOP`.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR and DSPSR to unknown values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for T32 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed.

Exception-generating instructions

These instructions are:

- `SVC`.
- `HVC`.
- `SMC`.
- `UDF`.
- `BKPT`.
- `HLT`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- `SVC` behaves as `DCPS1`.
- `HVC` behaves as `DCPS2`.
- `SMC` behaves as `DCPS3`.
- They generate the exception the instruction would generate in Non-debug state. The exception is taken as described in *Exceptions in Debug state* on page H2-6734

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

SMC must not generate a Secure Monitor Call exception from Non-secure state if EDSCR.SDD is set to 1.

Instructions that explicitly write to the PC (branches)

These instructions are:

- B, B (conditional), CBZ, CBNZ BL.
- BX, BLX (register or immediate).
- BXJ, TBB, TBH.
- MOV pc and related instructions.
- LDR pc, LDM (with a register list includes the PC), POP (with a register list that includes the PC).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set DSPSR and DLR to UNKNOWN values.

Exception return and related instructions, other than ERET

These instructions are:

- SRS, RFE, SUBS pc, 1r, and related instructions.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching, setting DLR and DSPSR to UNKNOWN values, and either:
  - Execute the DRPS operation instead of performing an exception return, using UNKNOWN SPSR values.
  - Not changing Exception level or PE mode.

Instructions that request entry to a low-power state

These instructions are:

- WFE, WFI.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See *Configurable instruction enables and disables, and trap controls* on page G1-5576.
- A WFE instruction is permitted to clear the Event register if it is set.

Note

This means that these instructions must not suspend execution.

Instructions that read the PC

These instructions are:

- LDR (literal), LDRB (literal), LDRH (literal), LDRSB (literal), LDRSH (literal).
- ADR, ADRL, ADRH.
- PLD (literal), PLI (literal).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state using an UNKNOWN value for the PC operand.

Instructions that explicitly modify **PSTATE, other than `DCPS` and `ERET`**

These instructions are:

- `CMP, TST, TEQ, CMN.`
- `<opc>S`.
- `MRC p14,0,APSR_nzcv,c0,c1,0` (accessing DBGDSCRint).
- `CPS, SETEND, IT`.
- `MSR CPSR` (immediate), `MSR CPSR` (register), `MSR APSR` (immediate), `MSR APSR` (register).
- `VMRS APSR_nzcv,FPSCR`.
- `QADD, QDADD, QSUB, QDSUB`.
- SMLABB. SMLABT, SMLATB, SMLATT, SMLAD, SMLAWB, SMLAWT, SMLSD, SMUAD.
- `SSAT, SSAT16, USAT, USAT16`.
- SADD, SADD8, SADD16, SASX, SSAX, SSUB, SSUB8, SSUB16.
- UADD, UADD8, UADD16, UASX, USAX, USAUB, USUN8, USUB16.
- When ARMv8.1-PAN is implemented, `SETPAN`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- `SEL`, `VSEL`.
- `ADC`, `SBC`, all instructions with an `RRX` shift.
- `MRS CPSR.`

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state:
  - For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the Condition flag.
  - For the `MRS` instruction, they return an UNKNOWN value

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They have the same behavior as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are CONSTRAINED UNPREDICTABLE in Debug state. This includes some T32 instructions that specify R15 as a destination or source register.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors* describes the CONSTRAINED UNPREDICTABLE behavior for these instructions. In Debug state these CONSTRAINED UNPREDICTABLE choices are further restricted:

- Instructions that specify R15 as a destination register:
  - Are not permitted to branch, because the architecture does not define a branch operation in Debug state.
  - Might set DLR and DSPSR to UNKNOWN values.
  - Might have any of the other permitted behaviors.
- Instructions that specify R15 as a source operand:
  - Cannot use PC + offset, because there is no architecturally-defined PC in Debug state.
  - Might have any of the other permitted behaviors, including using an UNKNOWN value.

H2.4.3 Decode tables

The syntax in the tables is defined as follows:

1 The bit has a fixed value of 1.

0 The bit has a fixed value of 0.

!= The field has any value other than the value or values specified. The field might be an encoding field in the instruction whose value is supplied by the debugger.

Note

The instruction encodings in Chapter C6 *A64 Base Instruction Descriptions* and Chapter F5 *T32 and A32 Base Instruction Set Instruction Descriptions* might show these bits as (0) or (1). A debugger must set these bits to 0 or 1, as appropriate.

Any other value indicates an encoding field in the instruction whose value is supplied by the debugger. Some values might be reserved or undefined, in which case the instruction is UNDEFINED or CONSTRAINED UNPREDICTABLE in Debug state, as it is in Non-debug state.

For more information about the instruction encodings, see:

- Chapter C6 *A64 Base Instruction Descriptions*.
- Chapter F5 *T32 and A32 Base Instruction Set Instruction Descriptions*.

For information about the syntax used in Table H2-2, Table H2-3 on page H2-6727, Table H2-4 on page H2-6727, and Table H2-5 on page H2-6728, see:

- *Common syntax terms* on page C1-171.
- *Assembler symbols* on page F2-3905.

Table H2-2 shows the A64 instructions that are modified in Debug state. For details of how these are packed in the EDITR see the register description.

Table H2-2 Modified A64 instructions in Debug state

H2.4.4 Security in Debug state

If EL3 is implemented or the implemented Security state is Secure state, security in Debug state is governed by the Secure debug disabled flag, EDSCR.SDD.

On entry to Debug state

If entering in Secure state, EDSCR.SDD is set to 0. Otherwise EDSCR.SDD is set to the inverse of `ExternalSecureInvasiveDebugEnabled()`. That is:

- If `ExternalSecureInvasiveDebugEnabled()` == TRUE, EDSCR.SDD is set to 0.
- If `ExternalSecureInvasiveDebugEnabled()` == FALSE, EDSCR.SDD is set to 1.

Note

Normally, if `ExternalSecureInvasiveDebugEnabled()` == FALSE then halting is prohibited and it is not possible to enter Debug state from Secure state. However, because changes to the authentication signals require a *Context synchronization event* to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

In Debug state

The value of EDSCR.SDD does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

Note

- DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID} are not frozen in Debug state.
- If EDSCR.SDD set to 1 in Debug state, then there is no means to enter Secure state from Non-secure state. In this case it is impossible for the PE to be in Secure state. This is a general principle of behavior in Debug state.

In Non-debug state

EDSCR.SDD returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a *Context synchronization event* is required to guarantee their effect.

Note

- In Non-debug state, EDSCR.SDD is unaffected by the Security state of the PE.
- A *Context synchronization event* is also required to guarantee that changes in the authentication signals are visible in DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID}.

If EL3 is not implemented and the implemented Security state is Non-Secure state, EDSCR.SDD is RES1.

H2.4.5 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute *Debug state operations, DCPS, DRPS, MRS, MSR*.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be undefined or trapped in Non-debug state. These instruction are:

- The `MRS` and `MSR` instructions that access DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 in AArch64 state.
- The `MRC` and `MCR` instructions that access DBGDTRTXint and DBGDTRRXint in AArch32 state.

All other instructions operate with the privilege determined by the current Exception level and security state. This applies to all Special-purpose and System registers accesses, memory accesses, and undefined instructions, and includes generating exceptions when the System registers trap or disable an instruction.

H2.4.6 Debug state operations, DCPS, DRPS, MRS, MSR

Armv8 defines operations to change between Exception levels in Debug state. These operations can also change the mode at the current Exception level.

DCPS<n>

Executing a `DCPS<n>` instruction in Debug state moves the PE to a higher Exception level or to a specific mode at the current Exception level.

If the `DCPS<n>` instruction is executed in AArch32 state and the target Exception level is using AArch64:

- The current instruction set switches from T32 to A64.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for system calls in Non-debug state. See *Execution state* on page D1-2271.

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE might change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- In AArch64 state the current endianness is determined by the value of SCTLR_ELx.EE for the target Exception level.
- In AArch32 state the current endianness is determined by the value of SCTLR.EE or HSCTLR.EE for the target Exception level.

The `DCPS<n>` instructions are:

In AArch64 state

- `DCPS1`
- `DCPS2`
- `DCPS3`

In AArch32 state, in the T32 instruction set only

- `T1 variant`
- `T1 variant`
- `T1 variant`

The `DCPS` instructions are undefined in Non-debug state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table H2-6 shows the target of the instruction. In Table H2-6 the entries have the following meaning:

EL1h/Svc This means that the target is:
- EL1h if EL1 is using AArch64.
- EL1 and Supervisor mode if EL1 is using AArch32.

EL2h/Hyp This means that the target is:
- EL2h if EL2 is using AArch64.
- EL2 and Hyp mode if EL2 is using AArch32.

EL3h/Monitor This means that the target is:
- EL3h if EL3 is using AArch64.
- EL3 and Monitor mode if EL3 is using AArch32.

Svc Secure Supervisor mode, in EL3 using AArch32.

Monitor Secure Monitor mode, in EL3 using AArch32.

Table H2-6 Target for DCPS instructions in Debug state

Instruction	Target when DCPS instruction executed at stated Exception level:				
	EL0	EL1	EL2	EL3 (AArch64)	EL3 (AArch32)
DCPS1	EL1h/Svc	EL1h/Svc	EL2h/Hyp	EL3h	Svc, clears SCR.NS to 0
DCPS2	EL2h/Hyp	EL2h/Hyp	EL2h/Hyp	EL3h	UNDEFINED
DCPS3	EL3h/Monitor	EL3h/Monitor	EL3h/Monitor	EL3h	Monitor, clears SCR.NS to 0

In AArch32 Monitor mode, DCPS1 and DCPS3 clear SCR.NS to 0.

Note

In AArch64 state, at EL3, DCPS<n> does not change SCR_EL3.NS.

However:

- DCPS1 is undefined at EL0 if either:
  - EL2 is implemented and enabled in the current Security state, and is using AArch64 and HCR_EL2.TGE == 1.
  - In Non-secure state, EL2 is implemented and using AArch32 and HCR.TGE == 1.
- DCPS2 is undefined at all Exception levels if EL2 is not implemented.
- DCPS2 is undefined at the following Exception levels if EL2 is implemented:
  - At EL0 and EL1 in Secure state if EL2 is disabled in the current Security state.
  - At EL3 if EL3 is using AArch32.
- DCPS3 is undefined at all Exception levels if either:
  - EDSCR.SDD == 1.
  - EL3 is not implemented.

Note

The references to DCPS1, DCPS2, and DCPS3 in this section link to the descriptions of the instructions in the A64 instruction set. The DCPS<n> instructions are also defined in the T32 instruction set, see DCPS1, DCPS2, DCPS3. These instructions are not defined in the A32 instruction set, because A32 instructions cannot be executed in Debug state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On executing a DCPS instruction:

- If the target Exception level is using AArch64:
  - ELR_ELx of the target Exception level becomes UNKNOWN.
  - SPSR_ELx of the target Exception level becomes UNKNOWN.
  - ESR_ELx of the target Exception level becomes UNKNOWN.
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32 DLR and DSPSR become UNKNOWN and:
  - If the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.
  - If the target Exception level is EL2, then ELR_hyp, SPSR_hyp, and HSR become UNKNOWN.

If the target Exception level is using AArch32, and the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.

If ARMv8.0-SSBS is implemented, the DCPS<n> instruction leaves the PSTATE.SSBS bit UNKNOWN.

The DCPSInstruction() function is described in Chapter J1 *Armv8 Pseudocode*.

DRPS

Executing the DRPS operation in Debug state moves the PE to a lower Exception level, or to another PE mode at the current Exception level, by copying the current SPSR to PSTATE.

If DRPS is executed in AArch64 state and the target Exception level is using AArch32:

- The current instruction set switches from A64 to T32.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for exception returns in Non-debug state. See *Execution state* on page D1-2271.

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE might change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- If targeting an Exception level using AArch64, current endianness is set according to SCTLR_ELx.EE, or SCTLR_EL1.E0E for the target Exception level.
- If targeting an Exception level using AArch32, current endianness is set by SPSR.E as appropriate.

The DRPS instructions are:

In AArch64 state

- DRPS

In AArch32 state, in the T32 instruction set only

- ERET

If the SPSR specifies an illegal exception return, then PSTATE.{M, nRW, EL, SP} are unchanged and PSTATE.IL is set to 1. For further information on illegal exception returns, see *Illegal return events from AArch64 state* on page D1-2304.

PSTATE.{N, Z, C, V, Q, GE, IT, T, SS, D, A, I, F} are ignored in Debug state. This means that the effect of the DRPS operation on these fields is to set them to an UNKNOWN value that might be the value from the SPSR. For more information see *PSTATE in Debug state* on page H2-6714.

All other PSTATE fields are copied from SPSR.

DRPS is undefined at EL0 and in Non-debug state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Unlike an exception return, the DRPS operation has no architecturally-defined effect on the Event Register and Exclusives monitors. DRPS might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

On executing a DRPS instruction:

- If the target Exception level is using AArch64:
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32:
  - DLR and DSPSR become UNKNOWN.

If ARMv8.0-SSBS is implemented, the DRPS instruction leaves the PSTATE.SSBS bit UNKNOWN.

The DRPSInstruction() function is described in Chapter J1 *Armv8 Pseudocode*.

MRS and MSR

The other Debug state instructions are used to read or write DLR_EL0 and DSPSR_EL0.

These instructions are:

In AArch64 state

- MRS
- MSR (register)

In AArch32 state

- MRC
- MCR

```
MRS <Xt>, DLR_EL0      ; Copy DLR_EL0 to <Xt>
MRS <Xt>, DSPSR_EL0    ; Copy DSPSR_EL0 to <Xt>
MSR DLR_EL0, <Xt>      ; Copy <Xt> to DLR_EL0
MSR DSPSR_EL0, <Xt>    ; Copy <Xt> to DSPSR_EL0
```

These instructions can be executed at any Exception level when in Debug state, including EL0. They are undefined in Non-debug state.

H2.4.7 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- *Generating exceptions when in Debug state*.
- *Taking exceptions when in Debug state* on page H2-6735.
- *Reset in Debug state* on page H2-6736.

Generating exceptions when in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
  - The pending interrupt remains visible in ISR.
- Debug exceptions and debug events are ignored.
- SCR.EA is treated as if it were set to 0, regardless of its actual state, other than for the purpose of reading the bit.
- Any attempt to execute an instruction bit pattern that is an allocated instruction at the current Exception level, but is listed in *Executing instructions in Debug state* on page H2-6715 as undefined in Debug state, generates an exception, that is taken to the current Exception level, or to EL1 if executing at EL0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If the exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.

- Instructions executed at EL2, EL1 and EL0 that are configured by EL3 control registers to trap to EL3:
  - When the value of EDSCR.SDD is 0, generate the appropriate trap exception that is taken to EL3.
  - When the value of EDSCR.SDD is 1, are treated as UNDEFINED and generate an exception that is taken to the current Exception level, or to EL1 if the instruction is executed at EL0. If the exception is taken to an Exception level that is using AArch32 it is taken as an Undefined Instruction exception.

    If the exception is taken to an Exception level using AArch64 or to AArch32 Hyp mode, then it is reported with an EC value of `0x00`.

  Otherwise configurable traps, enables, and disables for instructions are unaffected by Debug state, and executing an affected instruction generates the appropriate exception.

Otherwise, synchronous exceptions, including Data Aborts, are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

Note

If EDSCR.SDD == 1 then an exception from Non-secure state is never taken to Secure state. See *Security in Debug state* on page H2-6730.

Taking exceptions when in Debug state

When the PE is in Debug state, all exceptions are synchronous. When an exception is generated, it is taken to Debug state. This means that:

- The target Exception level is as defined for the exception in Non-debug state.
- If the target Exception level is using AArch32 then the target PE mode is as defined for the exception in Non-debug state.
- The exception syndrome is reported as defined for the exception in Non-debug state, except for the case described in *Data Aborts in Memory access mode* on page H4-6774 for which the reporting requirements are relaxed.

  The exception syndrome is reported using the syndrome register or registers for the target Exception level. In AArch64 state, these are ESR_ELx, and FAR_ELx. In AArch32 state, these are DFSR, DFAR, HSR, HDFAR, and HPFAR. For example:
  - If a Data Abort exception is taken to Abort mode at EL1 or EL3 and the exception is taken from AArch32 state and using the Short-descriptor translation table format, the DFSR reports the exception using the Short-descriptor format fault encoding. For exceptions other than Data Abort exceptions taken to Abort mode, DFSR is not updated.
  - If an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

  The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.

  Note

  Generally, the AArch32 Fault Address Registers (FARs) and Fault Status Registers (FSRs) are not described as *syndrome registers*, although the term is appropriate to their function.
- The PE remains in Debug state and changes to the target mode.
- If EL3 is using AArch32 and the exception is taken from Monitor mode, SCR.NS is cleared to 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the exception is taken to an Exception level using AArch32, the PE continues to execute T32 instructions, regardless of the TE bit in the System register for the target Exception level.
- The endianness switches to that indicated by the EE bit of the System register for the target Exception level.
- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
- If the target Exception level is using AArch64, ELR_ELx for the target Exception level becomes unknown.
- If the target Exception level is EL2 using AArch32, ELR_hyp becomes unknown.
- If the target Exception level is EL1 or EL3 using AArch32, LR_<mode> for the target mode becomes unknown.
- DLR and DSPSR become UNKNOWN.
- The cumulative error flag, EDSCR.ERR, is set to 1. See *Cumulative error flag* on page H4-6778.
- PSTATE.IL is cleared to 0.
- PSTATE.{IT, T, SS, D, A, I, F} are set to UNKNOWN values, and PSTATE.{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information see *PSTATE in Debug state* on page H2-6714.

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

Pseudocode description of taking exceptions in Debug state

The pseudocode function `AArch64.TakeException()` shows the behavior when the PE takes an exception to an Exception level using AArch64 in Non-debug state. In Debug state, this is replaced with the function `AArch64.TakeExceptionInDebugState()`.

The pseudocode functions `AArch32.EnterMode()`, `AArch32.EnterHypMode()`, and `AArch32.EnterMonitorMode()` show the behavior when the PE takes an exception to an Exception level using AArch32 in Non-debug state. In Debug state:

- `AArch32.EnterMode()` is replaced with the function `AArch32.EnterModeInDebugState()`.
- `AArch32.EnterHypMode()` is replaced with the function `AArch32.EnterHypModeInDebugState()`.
- `AArch32.EnterMonitorMode()` is replaced with `AArch32.EnterMonitorModeInDebugState()`.

Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, EDSCR.STATUS == `0b000010` and writes to EDITR are ignored.

Note

If EDECR.RCE == 1 or CTIDEVCTL.RCE ==1, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and re-enters Debug state. See *Reset Catch debug events* on page H3-6763. All PE registers have taken their reset values, which might be UNKNOWN.

H2.4.8 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

General-purpose register access, other than AArch64 state SP access

A single general-purpose register can be read by issuing an `MSR` instruction through the ITR to write DBGDTR_EL0 in AArch64 state, or an `MCR` instruction through the ITR to write DBGDTRTXint in AArch32 state. The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

Figure H2-1 shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

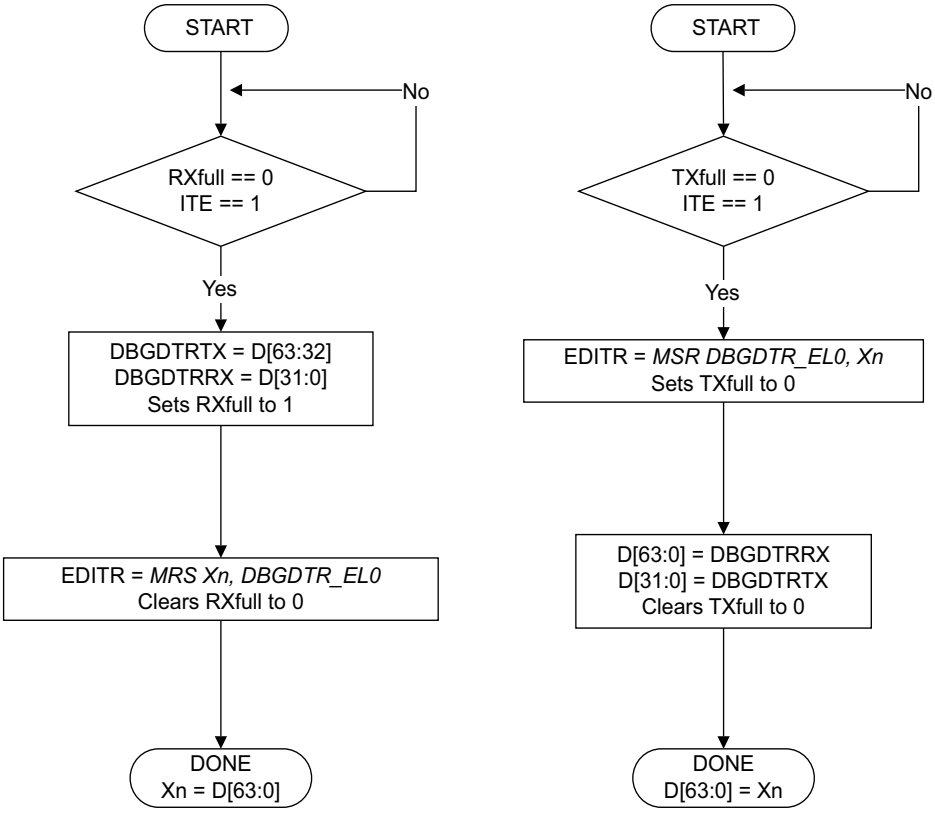

Figure H2-1 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state

Figure H2-2 on page H2-6738 shows the reading and writing of general-purpose registers in Debug state in AArch32 state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

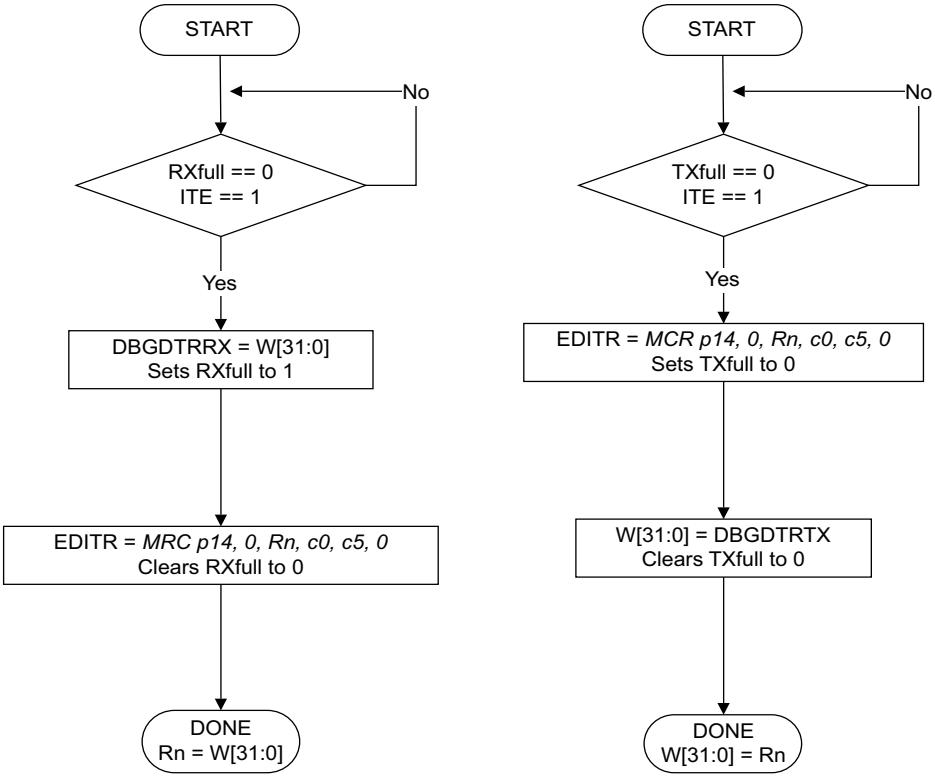

Figure H2-2 Reading and writing general-purpose registers in Debug state in AArch32 state

SIMD and floating-point register, System register, and AArch64 state SP accesses

To read a SIMD and floating-point register or a System register, the debugger must first copy the value into a general-purpose register using:

- An `FMOV` instruction in AArch64 state or a `VMOV` instruction in AArch32 state for floating-point transfers to SIMD and FP registers.
- A `UMOV` instruction in AArch64 state or a `VMOV` instruction in AArch32 state for SIMD transfers to SIMD and FP registers.
- An `MRS` instruction in AArch64 state or an `MRC` instruction in AArch32 state for System registers.
- A `MOV Xd,SP` instruction for the SP register in AArch64 state.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

PC and PSTATE access

The debugger reads the program counter and PSTATE of the process being debugged through the DLR_EL0 and DSPSR_EL0 System registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are UNDEFINED in Debug state.
- On taking an exception, ELR_ELx and SPSR_ELx at the target Exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE.{IL, E, M, nRW, EL, SP} are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- *PSTATE in Debug state* on page H2-6714.
- *Executing instructions in Debug state* on page H2-6715.
- *Exceptions in Debug state* on page H2-6734.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.4.9 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU, including address translation, tagged address handling, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.

Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. *Executing instructions in Debug state* on page H2-6715 lists the memory access instructions that are supported in Debug state.

Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See *DCC and ITR access modes* on page H4-6772.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If EDSCR.ITE == 0 the behavior of any instruction issued through the ITR in Normal access mode or an operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state after the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Note

- Implementations can set EDSCR.ITE to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and EDSCR.ITE == 1, then the PE must complete these instructions in Debug state before executing the restart sequence. EDSCR.ITE == 0 indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through EDITR that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the EDSCR.{TXfull, RXfull} flags.

On exiting Debug state, the PE sets the program counter to the address in DLR, where:

- If exiting to AArch32 state:
  - Bits[31:1] of the PC are set to the value of bits[31:1] of DLR.
  - Bit[0] of the PC is set to a CONSTRAINED UNPREDICTABLE choice of 0 or the value of bit[0] in DLR.
- If exiting to AArch64 state:
  - Bits[63:56] of DLR_EL0 might be ignored as part of tagged address handling. See *Address tagging in AArch64 state* on page D5-2506.
  - Otherwise the PC is set from DLR_EL0.

Note

Bits[63:32] of DLR_EL0 are ignored when exiting to AArch32 state.

Exit from Debug state can give rise to a PC alignment fault exception when the program counter is used. Unlike an exception return, this might also happen when returning to AArch32 state. For more information, see *PC alignment checking* on page D1-2287.

On exiting Debug state, PSTATE is set from DSPSR in the same way that an exception return sets PSTATE from SPSR_ELx:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on PSTATE and the PC is the same as for any other illegal exception return. See *Exception return* on page D1-2303 and *Exception return to an Exception level using AArch32* on page G1-5523.
- The checks on the PSTATE.IT bits that apply to exiting Debug state into AArch32 state are the same as those that apply to an exception return. See Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.
- PSTATE.SS is copied from DSPSR.SS if all of the following hold:
  - MDSCR_EL1.SS == 1.
  - The debug target Exception level is using AArch64.
  - Software step exceptions from the restart Exception level are enabled.

  Otherwise PSTATE.SS is set to 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Unlike a return using ERET, PSTATE.SS must be restored from DSPSR.SS because otherwise it is UNKNOWN.

However, if OSDLR.DLK == 1 and DBGPRCR.CORENPDRQ == 0, meaning ARMv8.0-DoubleLock is implemented and locked in Non-debug state and therefore Software Step exceptions are disabled, but otherwise Software Step exceptions would be enabled from the restart Exception level, it is CONSTRAINED UNPREDICTABLE whether PSTATE.SS is copied from DSPSR.SS.

- If ARMv8.0-SSBS is implemented, on exit from Debug state to AArch64 state, DSPSR_EL0.SSBS is copied to PSTATE.SSBS.
- If ARMv8.0-SSBS is implemented, on exit from Debug state to AArch32 state, DSPSR.SSBS is copied to CPSR.SSBS.
- If ARMv8.1-PAN is implemented, DSPSR_EL0.PAN is copied to PSTATE.PAN.
- If ARMv8.2-UAO is implemented, DSPSR_EL0.UAO is copied to PSTATE.UAO.
- If ARMv8.4-DIT is implemented, on exit from Debug state to AArch64 state, DSPSR_EL0.DIT is copied to PSTATE.DIT.
- If ARMv8.4-DIT is implemented, on exit from Debug state to AArch32 state, DSPSR.DIT is copied to CPSR.DIT.
- If ARMv8.5-MemTag is implemented, on exit from Debug state to AArch64 state, DSPSR_EL0.TCO is copied to PSTATE.TCO. On exit from Debug state to AArch32 state, PSTATE.TCO is not updated.
- If ARMv8.5-BTI is implemented, DSPSR_EL0.BTYPE is copied to PSTATE.BTYPE.

Note

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, PSTATE.{D, A, I, F} is updated regardless of the value of SCTLR_EL1.UMA.
- Exit from Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors. An exit from Debug state might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

The `ExitDebugState()` function is described in Chapter J1 *Armv8 Pseudocode*.

Chapter H3
Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

- *Introduction to Halting debug events* on page H3-6744.
- *Halting Step debug events* on page H3-6746.
- *Halt Instruction debug event* on page H3-6756.
- *Exception Catch debug event* on page H3-6757.
- *External Debug Request debug event* on page H3-6761.
- *OS Unlock Catch debug event* on page H3-6762.
- *Reset Catch debug events* on page H3-6763.
- *Software Access debug event* on page H3-6764.
- *Synchronization and Halting debug events* on page H3-6765.

Note

Table K14-1 on page K14-7810 disambiguates the general register references used in this chapter.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available in Armv8:

- *Halting Step debug events* on page H3-6746.
- *Halt Instruction debug event* on page H3-6756.
- *Exception Catch debug event* on page H3-6757.
- *External Debug Request debug event* on page H3-6761.
- *OS Unlock Catch debug event* on page H3-6762.
- *Reset Catch debug events* on page H3-6763.
- *Software Access debug event* on page H3-6764.

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See *Breakpoint and Watchpoint debug events* on page H2-6706. Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see Chapter H2 *Debug State*. For a definition of halting allowed, see *Halting allowed and halting prohibited* on page H2-6705.

Debug state entry and debug event prioritization on page H2-6707 describes the behavior when multiple debug events are generated by an instruction.

See also *Synchronization and Halting debug events* on page H3-6765.

Table H3-1 shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

Table H3-1 Summary of debug events and possible outcomes

Debug event type	PE behavior when halting is:	
	Allowed	Prohibited
Breakpoint and Watchpoint debug events on page H2-6706	Halt	See Table D2-1 on page D2-2400 and Table G2-1 on page G2-5615
Halt Instruction debug event on page H3-6756	Halt	UNDEFINED
Software Access debug event on page H3-6764	Halt	Ignored
Exception Catch debug event on page H3-6757	Halt	Ignored
Halting Step debug events on page H3-6746	Halt	Pended
External Debug Request debug event on page H3-6761	Halt	Pended
Reset Catch debug events on page H3-6763	Halt	Pended
OS Unlock Catch debug event on page H3-6762	Pended	Pended

Table H3-2 shows where the pseudocode for each Halting debug event type is located.

Table H3-2 Pseudocode description of Halting debug events

Halting debug event type	Pseudocode
Halt Instruction debug event on page H3-6756	*HLT* on page C6-908 for AArch64 and *HLT* on page F5-4199 for AArch32

H3.2 Halting Step debug events

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- *Overview of a Halting Step debug event*.
- *The Halting Step state machine*.
- *Using Halting Step* on page H3-6749.
- *Detailed Halting Step state machine behavior* on page H3-6749.
- *Synchronization and the Halting Step state machine* on page H3-6752.
- *Stepping T32 IT instructions* on page H3-6754.
- *Disabling interrupts while stepping* on page H3-6754.
- *Syndrome information on Halting Step* on page H3-6754.
- *Pseudocode description of Halting Step debug events* on page H3-6755.

The architecture describes the behavior as a simple Halting Step state machine. See *The Halting Step state machine*.

H3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in Figure H3-1 on page H3-6748. A Halting Step debug event executes a single instruction and then returns control to the debugger. When the debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, EDECR.SS and EDESR.SS.

Note

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

H3.2.2 The Halting Step state machine

The state machine states are:

Inactive Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:

- Halting Step is disabled. That is, EDECR.SS is set to 0 and EDESR.SS is set to 0.
- Halting is prohibited. See *Halting the PE on debug events* on page H2-6705. In this state, if EDECR.SS is set to 1 then a Halting Step debug event is pending.

In Figure H3-1 on page H3-6748 this state is shown in red.

Active-not-pending

Halting Step is enabled and active. This is the state in which the PE steps an instruction. EDECR.SS == 1 and EDESR.SS == 0. Software must not set EDECR.SS to 1 unless the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE, as described in *Changing the value of EDECR.SS when not in Debug state* on page H3-6753.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In Figure H3-1 on page H3-6748 this state is shown in green.

Active-pending

Halting Step is enabled and active. The step has completed, and the PE enters Debug state. EDESR.SS == 1.

In Figure H3-1 on page H3-6748 this state is shown in green.

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on EDESR.SS. *Halting Step state machine states* on page H3-6749 shows this.

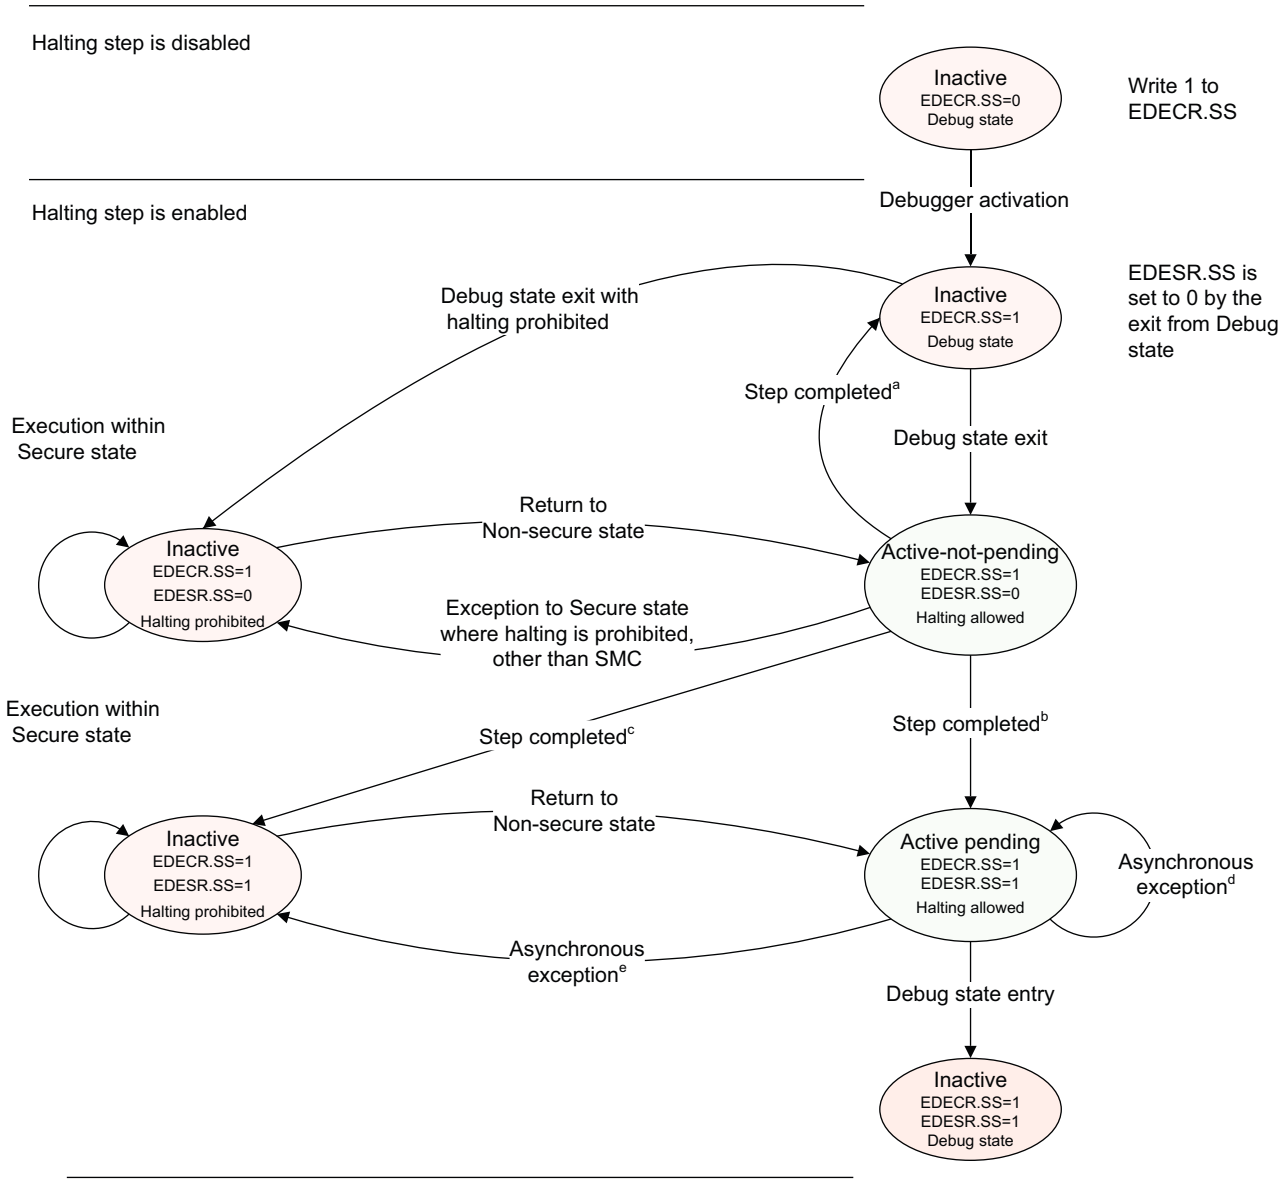
In the simple sequential execution of the program the PE executes the Halting Step state machine, as follows:

1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

Figure H3-1 on page H3-6748 shows a Halting Step state machine.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



a. Step completed occurs when:
   - A debug event, other than a Halting Step debug event, causes entry into Debug state.

b. Step completed occurs when:
   - An instruction is executed without taking an exception.
   - An exception is taken to a state where halting is allowed.
   - A reset.

c. Step completed occurs when:
   - An SMC exception is taken to Secure state where halting is prohibited.

d. An asynchronous exception taken to a state where halting is allowed.

e. An asynchronous exception taken to Secure state where halting is prohibited.

Figure H3-1 Halting Step state machine

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Figure H3-1 on page H3-6748 only describes state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as EDECR and OSDLR and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior. See *Synchronization and the Halting Step state machine* on page H3-6752.

The following bits control the state machine, as shown in Table H3-3:

- EDECR.SS. This is the Halting Step enable bit.
- EDESR.SS. This is the Halting Step debug event pending bit.

Table H3-3 shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

Table H3-3 Halting Step state machine states

Halting	EDECR.SS	EDESR.SS	Halting Step state
Prohibited	X	X	Inactive (Halting Step debug even not pending)
Prohibited	X	1	Inactive (Halting Step debug event pending).
Allowed	0	0	Inactive
Allowed	1	0	Active-not-pending
Allowed	X	1	Active-pending

H3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets EDECR.SS to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with DLR set to the address of the instruction being stepped. The PE clears EDESR.SS to 0 and the Halting Step state machine enter the active-not-pending state.
3. The PE executes the instruction being stepped.

   If an exception is taken to a state where halting is prohibited, then EDESR.SS is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

Note

- If ARMv8.3-DoPD is not implemented, EDECR.SS value is in the Debug power domain, meaning that the state machine is maintained over a powerdown of the Core power domain.
- If ARMv8.3-DoPD is implemented, the values of EDECR.SS and EDESR.SS are set to 0 on a Cold reset, and, if the PE was stepping an instruction, EDESR.SS is effectively UNKNOWN after a Warm reset. A debugger must use a Reset Catch debug event to step over a powerdown state.
- A debugger must only change the value of EDECR.SS when the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE as described in *Changing the value of EDECR.SS when not in Debug state* on page H3-6753.

H3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

- *Entering the active-not-pending state* on page H3-6750.
- *PE behavior in the active-not-pending state* on page H3-6750.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- *Entering the active-pending state* on page H3-6751.
- *PE behavior in the active-pending state* on page H3-6752
- *PE behavior in the inactive state when in Non-debug state* on page H3-6752.
- *PE behavior in Debug state* on page H3-6752.

Entering the active-not-pending state

The PE enters the active-not-pending state:

- By exiting Debug state with EDECR.SS == 1.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with EDECR.SS == 1 and EDESR.SS == 0.
- As described in *Synchronization and the Halting Step state machine* on page H3-6752.

PE behavior in the active-not-pending state

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
  - Completes it without generating a synchronous exception.
  - Generates a synchronous exception.
  - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

If no exception or debug event is generated

If no exception or debug event is generated the PE sets EDESR.SS to 1. This means that the Halting Step state machine advances to the active-pending state.

If an exception or debug event is generated

The PE sets EDESR.SS according to all of the following:

- The type of exception.
- The target Exception level of the exception.
- If the exception is taken to Secure state, whether halting is prohibited in Secure state.
  - This is determined by the result of ExternalSecureInvasiveDebugEnabled().

If an exception or debug event is generated, the PE sets EDESR.SS to 1 if one of the following applies:

- A synchronous exception is generated by the instruction and one of the following applies:
  - The exception is taken to EL1 or EL2.
  - The exception is taken to EL3, it is not an SMC exception, and `ExternalSecureInvasiveDebugEnabled()` == TRUE.
  - The exception is an SMC exception.
- An asynchronous exception is generated before executing an instruction and this is either:
  - Taken to EL1 or EL2.
  - Taken to EL3 and `ExternalSecureInvasiveDebugEnabled()` == TRUE.
- A PE reset occurs.

Otherwise EDESR.SS is unchanged. This happens when:

- No instruction is executed because either:
  - An asynchronous exception is taken to EL3 and `ExternalSecureInvasiveDebugEnabled()` == FALSE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - An asynchronous debug event causes entry to Debug state.

- An instruction is executed and either:
  - Generates a synchronous exception other than an SMC exception which is taken to EL3, and `ExternalSecureInvasiveDebugEnabled()` == FALSE.
  - Generates a synchronous debug event and causes entry to Debug state.

It is UNPREDICTABLE whether EDESR.SS is set to 1 or unchanged when an SError interrupt is taken to EL3 without executing the instruction, and `ExternalSecureInvasiveDebugEnabled()` == FALSE.

If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise the Halting Step state machine advances to the active-pending state.

Note

The underlying criteria for the value of EDESR.SS on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

Table H3-4 shows the behavior of the active-not-pending state. The letter X indicates that `ExternalSecureInvasiveDebugEnabled()` can be either TRUE or FALSE.

Table H3-4 Summary of active-not-pending state behavior

Event	Target Exception level	`ExternalSecureInvasiveDebugEnabled()`	Value written to EDESR.SS
No exception or debug event	Not applicable	X	1
SMC exception	EL3	X	1
Reset	Highest	X	1
Exception, other than SMC exception	EL1	X	1
	EL2	X	1
	EL3	TRUE	1
		FALSE	Unchanged
Debug event	Debug state	X	Unchanged

Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
  - Executing an instruction without taking an exception.
  - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when EDESR.SS == 1.

  Note

  That is, an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A reset when the value of EDECR.SS == 1, regardless of the state the PE was in before the reset occurred.
- From the active-pending state by taking an asynchronous exception to a state where halting is allowed.
- Following the description in *Synchronization and the Halting Step state machine*.

PE behavior in the active-pending state

When the PE is in the active-pending state, it enters Debug state before executing an instruction.

The entry into Debug state has higher priority than all other types of synchronous debug event and synchronous exception. However, the architecture does not define the prioritization of this Debug state entry with respect to any unmasked pending asynchronous exception. If an asynchronous exception is prioritized over the entry to Debug state, then EDESR.SS is unchanged.

For more information on the prioritization of debug events, see *Debug state entry and debug event prioritization* on page H2-6707.

PE behavior in the inactive state when in Non-debug state

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which in some situations is a *Context synchronization event*.

See also *Synchronization and the Halting Step state machine*.

PE behavior in Debug state

Halting Step is inactive in Debug state because halting is prohibited, see *Halting allowed and halting prohibited* on page H2-6705.

Entry to Debug state does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. If EDECR.SS == 1, Halting Step enters the active-not-pending state.

Note

This means that EDESR.SS is never cleared to 0 by the execution of an instruction in Debug state, or by taking an exception when in Debug state as described in *PE behavior in the active-not-pending state* on page H3-6750, because the Halting Step state machine is not in the active-not-pending state. EDESR.SS can be cleared by a write to EDESR, see the register description.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then Halting Step immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

H3.2.5 Synchronization and the Halting Step state machine

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
  - The security state changes without an exception return. See *State and mode changes without explicit context synchronization events* on page G2-5674.
  - The external authentication interface changes.
  - ARMv8.0-DoubleLock is implemented and the status, `DoubleLockStatus()`, changes.
- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Behavior is CONSTRAINED UNPREDICTABLE if the value of EDECR.SS is changed when the PE is in Non-debug state, see *Changing the value of EDECR.SS when not in Debug state*.

- A write to EDESR when the PE is in Non-debug state clears EDESR.SS to 0.

These operations are guaranteed to take effect only after a *Context synchronization event*. If the instruction being stepped generates a *Context synchronization event*, then the PE might use the old or new state.

The PE must perform the required behavior of the new state before or immediately following the next *Context synchronization event*, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next *Context synchronization event*. This is illustrated in Example H3-1 and Example H3-2.

Example H3-1 Synchronization requirements 1

EDECR.SS is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to Secure state. `ExternalSecureInvasiveDebugEnabled()` == FALSE, meaning that halting is prohibited in Secure state. The PE does not step any instructions but executes the software in Secure state as normal. EDESR.SS remains set to 0. If `ExternalSecureInvasiveDebugEnabled()` subsequently becomes TRUE, meaning that halting is now allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next *Context synchronization event*, but it is not required to do so immediately.

Example H3-2 Synchronization requirements 2

EDECR.SS is set to 1 in Debug state. On exit from Debug the PE executes an `MSR` instruction that sets OSDLR_EL1.DLK to 1 and `DoubleLockStatus()` becomes TRUE. This change requires a *Context synchronization event* to guarantee its effect, meaning it is CONSTRAINED UNPREDICTABLE whether:

- Halting is allowed:
  - The PE enters Debug state on the next instruction.
- Halting is prohibited:
  - The PE does not enter Debug state.

The value in EDESR.SS depends on whether halting was allowed or prohibited when the write to OSDLR_EL1.DLK completed, and so it might be 0 or 1. If a second `MSR` instruction clears OSDLR_EL1.DLK to 0, the PE must perform the required behavior of the state indicated by EDESR.SS before or immediately following the next *Context synchronization event*, but it is not required to do so immediately.

See also *Synchronization and Halting debug events* on page H3-6765.

Changing the value of EDECR.SS when not in Debug state

If software changes the value of EDECR.SS when the PE is not in Debug state then behavior is CONSTRAINED UNPREDICTABLE, and one or more of the following behaviors occurs:

- The value of EDECR.SS becomes UNKNOWN.
- The state of the Halting Step state machine becomes UNKNOWN.
- On a reset of the PE, the value of EDECR.SS and the state of the Halting Step state machine are UNKNOWN.

Non-Confidential

H3.2.6 Stepping T32 `IT` instructions

In an implementation that supports the ITD control, the architecture permits a combination of one T32 `IT` instruction and another 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers such a pair of instructions to be one instruction.
- The PE considers such a pair of instructions be two instructions.

It is IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD bit. For example:

- The debug logic might consider such a pair of instructions as one instruction, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as two instructions, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as one instruction when the value of the applicable ITD field is 1, and as two instructions when the value of the ITD field is 0.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

HSCTLR.ITD

Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD

Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD

Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

H3.2.7 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting EDSCR.INTdis, to allow the code being debugged to make forward progress.

H3.2.8 Syndrome information on Halting Step

Three EDSCR.STATUS encodings record different scenarios for entering Debug state on a Halting Step debug event:

Halting Step, normal

An instruction other than a Load-Exclusive instruction was stepped.

Halting Step, exclusive

A Load-Exclusive instruction was stepped.

Halting Step, no syndrome

The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, EDSCR.STATUS is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code check, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, EDSCR.STATUS is set to Halting Step, no syndrome. This happens when:

- The PE enters directly into the active-pending state on an exception return to Non-secure state from EL3 when Halting is prohibited in Secure state.
- The active-pending state is entered for other reasons. See *Synchronization and the Halting Step state machine on page H3-6752*

In addition, EDSCR.STATUS is CONSTRAINED UNPREDICTABLE when:

- The instruction being stepped generated a Halting Step debug event before the instruction was executed.

  In this case EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of:

  — Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.

  — Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.
- The instruction that was stepped was an Exception Return instruction or an `ISB`. As these instructions are not in the Load-Exclusive instructions, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.
- The PE enters directly into the active-pending state on reset because EDECR.SS is set to 1. EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.

In all cases, if EDSCR.STATUS is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting EDSCR.STATUS to Halting Step, normal or Halting Step, exclusive.

Note

In an implementation that always sets EDSCR.STATUS to Halting Step, no syndrome is not compliant.

H3.2.9 Pseudocode description of Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- `RunHaltingStep()`. This is called after an instruction has executed and any exception generated by the instruction is taken. It is also called after taking a reset before executing any instructions. That is, reset is treated like an asynchronous exception, even if EDECR.RCE == 1 or CTIDEVCTL.RCE == 1. `RunHaltingStep()` affects the next instruction.
- `CheckHaltingStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when EDSCR.HDE == 1, halting is allowed, and the PE executes the Halt instruction, HLT.

The pseudocode for Halt Instruction debug events is described in *HLT* on page C6-908 for A64 and *HLT* on page F5-4199 for A32 and T32.

HLT never generates a debug exception. It is treated as UNDEFINED if EDSCR.HDE == 0, or if halting is prohibited.

Note

A debugger can replace a program instruction with a Halt instruction to generate a Halt Instruction debug event. Debuggers that use the HLT instruction must be aware of the Armv8-A rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an HLT instruction when these same instructions are being executed by a different thread of execution. See *Concurrent modification and execution of instructions* on page B2-112.

The T32 HLT instruction is unconditionally executed inside an IT block, even when it is treated as undefined. The A32 HLT instruction is CONSTRAINED UNPREDICTABLE if the Condition code field is not 0b1110, with the set of behaviors the same as for BKPT. See Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Note

The HLT instruction is part of the external debug solution for Armv8-A. As such, the presence of the HLT instruction is not indicated in the ID registers. In particular, the AArch32 System register ID_ISAR0. Debug does not indicate the presence of the HLT instruction.

H3.3.1 HLT instructions as the first instruction in a T32 IT block

In an implementation that supports the ITD control, the architecture permits a combination of one T32 IT instruction and certain other 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

The T32 HLT instruction cannot be combined with an IT instruction in this way. In an implementation that supports the ITD control, if the first instruction in an IT block is an HLT instruction, then the behavior of the instruction depends on the value of the applicable ITD field:

- If the value of the ITD field is 1, then the combination is treated as undefined and an Undefined Instruction exception is generated either by the IT instruction or by the HLT instruction.
- If the value of the ITD field is 0, then the HLT instruction unconditionally executed.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

To set an Halt Instruction debug event on the first instruction of an IT block, debuggers must replace the IT instruction with an HLT instruction to ensure consistent behavior.

The ITD control fields are:

HSCTLR.ITD
Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD
Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD
Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

Note

An HLT instruction is always unconditional, even within an IT block.

Non-Confidential

H3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, EDECCR, is set to 1 on all entries to a given Exception level. This means:
  - Exceptions taken to the Exception level.
  - Exception returns to the Exception level.
- Are taken synchronously, after entry to the Exception level.
- Ignore the Execution state of the target Exception level.
- Are ignored if halting is prohibited.

From Armv8.2 the definition is extended to include generation of Exception Catch debug events on reset entry, see *Exception Catch debug events from Armv8.2* on page H3-6759.

The EDECCR contains two sets of fields:

- One set for Non-secure state.
- One set for Secure state.

Each set of fields control generation of Exception Catch debug events:

- On exception entry and, from Armv8.2, on reset entry.
- On exception return.

Each field within each set contains one bit for each Exception level in that state. Bits corresponding to Exception levels that are not implemented are RES0. For more information see the EDECCR description.

Note

- EDECCR does not replace DBGVCR:
  - DBGVCR is retained in AArch32 state for backwards compatibility.
  - DBGVCR is ignored in AArch64 state and never generates entries to Debug state.
  - DBGVCR cannot be accessed by the external debug interface.
- EDECCR is only visible as OSECCR_EL1 by System register instructions in AArch64 state, and as DBGOSECCR by System register access instructions in AArch32 state, when the OS Lock is locked to allow software to save and restore it over a powerdown.
- Exception Catch debug events are not disabled when the OS Lock is locked.

For an Exception Catch debug event generated after taking an exception to a trapped Exception level:

- The PE must not fetch instructions from the vector address before entering Debug state, if address translation is disabled in the translation regime at the target Exception level.
- On entering Debug state:
  - The current Exception level is the target Exception level of the exception.
  - The ELR, SPSR, ESR, and other syndrome registers contain information about the exception.
  - DLR contains the exception vector address or, from Armv8.2, the reset address.

H3.4.1 Prioritization of Exception Catch debug events

The following rules define the prioritization of Exception Catch debug events:

- It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than each of Software Step exceptions and Halting Step debug events.
- Exception Catch debug events are higher priority than all synchronous exceptions other than Software Step exceptions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Exception Catch debug events are lower priority than Reset Catch debug events.

Note

As described in *Synchronous exception prioritization for exceptions taken to AArch64 state* on page D1-2308, an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See *Vector Catch exceptions* on page D2-2445 or *Vector Catch exceptions* on page G2-5667.

A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

See also *Debug state entry and debug event prioritization* on page H2-6707.

From Armv8.2, when an Exception Catch debug event is generated on exception entry, the PE must enter Debug state as part of the exception entry:

- After the exception entry has updated the program counter, PSTATE and syndrome registers for the exception.
- Before the first instruction at the handler is executed.
- Before any asynchronous or lower priority synchronous exception or debug event is taken at the first instruction in the exception handler.

From Armv8.2, when an Exception Catch debug event is generated on exception return, the PE must enter Debug state:

- After the exception return has updated the program counter and PSTATE.
- Before the execution of the first instruction at the return address is completed.

Note

From Armv8.2, there is no prioritization between asynchronous exceptions, asynchronous debug events, and an Exception Catch debug event generated on an exception return.

H3.4.2 CONSTRAINED UNPREDICTABLE generation of Exception Catch debug events

When ARMv8.2-Debug is not implemented, the PE is executing code at a given Exception level, and the corresponding EDECCR bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

Note

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in *Detailed Halting Step state machine behavior* on page H3-6749.

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an `ISB` operation executed at the Exception level.

Examples of this are:

- If the debugger writes to EDECCR so that the current Exception level is trapped.
- If the OS restore code writes to OSECCR so that the current Exception level is trapped.
- If the code executing in AArch32 state changes the Exception level or security state other than by an exception return, and the target Exception level is trapped. See *State and mode changes without explicit context synchronization events* on page G2-5674.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When ARMv8.2-Debug is implemented, there are no CONSTRAINED UNPREDICTABLE cases that are permitted to generate Exception Catch debug events.

H3.4.3 Exception Catch debug events from Armv8.2

From Armv8.2, the definition of Exception Catch debug events is extended so that Exception Catch debug events can be generated from:

- Exception entry.
- Reset entry.
- Exception return.

It is IMPLEMENTATION DEFINED whether a reset into an Exception level generates an Exception Catch debug event.

Exception catch debug events are taken synchronously, after the exception or reset entry or the exception return has been processed by the PE.

For exception returns, the final Exception level of the exception return determines whether an Exception Catch debug event is generated. On an illegal exception return an Exception Catch debug event is generated only if EDECCR is programmed to generate an Exception Catch debug event for an exception return to the current Exception level.

The NSR and SR fields in EDECCR determine whether Exception Catch debug events can be generated from reset entry. Table H3-5 shows how exception entry and exception return Exception Catch debug events are enabled by a combination of the fields NSR, SR, NSE and SE in EDECCR.

Table H3-5 Summary of Exception Catch debug event control

(N)SR<n>	(N)SE<n>	Behavior on exception return to ELn	Behavior on exception taken to ELn
0	0	No action.	No action.
0	1	Halt if allowed.	Halt if allowed.
1	0	Halt if allowed.	No action.
1	1	No action.	Halt if allowed.

H3.4.4 Examples of Exception Catch debug events

If EDECCR == `0x20`, meaning that the Exception Catch debug event is enabled for Non-secure EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to Non-secure EL1.
- An exception return from EL2 to Non-secure EL1.
- An exception return from EL3 to Non-secure EL1.

For example, on taking a Data Abort exception from Non-secure EL0 to Non-secure EL1, using AArch64:

- ELR_EL1 and SPSR_EL1 are written with the preferred return address and PE state for a return to EL0.
- ESR_EL1 and FAR_EL1 are written with the syndrome information for the exception.
- DLR_EL0 is set to VBAR_EL1 + `0x400`, the synchronous exception vector.
- DSPSR_EL0 is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from EL0 to EL2, if enabled in the current Security state, or EL3.
- An exception return from EL2, if enabled in the current Security state, to EL0.
- An exception taken from Secure EL0 to Secure EL1.
- An exception return from EL3 to Secure EL1.

H3.4.5 Pseudocode description of Exception Catch debug events

The pseudocode function `CheckExceptionCatch()` is described in Chapter J1 *Armv8 Pseudocode*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H3.5 External Debug Request debug event

External Debug Request debug events are asynchronous debug events.

An External Debug Request debug event is generated when signaled by the embedded cross-trigger. See Chapter H5 *The Embedded Cross-Trigger Interface*.

Note

Armv8-A requires the implementation of an embedded cross-trigger.

An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

H3.5.1 Synchronization and External Debug Request debug events

An External Debug Request debug event that is asserted before a *Context synchronization event* is taken and the PE enters Debug state before the first instruction following the *Context synchronization event* completes its execution, provided that halting is allowed after completion of the *Context synchronization event*.

An External Debug Request debug event that is being asserted when the PE comes out of reset is taken, and the PE enters Debug state before the first instruction after the reset completes its execution, provided that halting is allowed when the PE exits reset state.

If the first instruction after the *Context synchronization event* or after coming out of reset generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

Otherwise, when halting is allowed, External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface.

Note

These rules are based on the rules that apply when taking asynchronous exceptions. See *Asynchronous exception types, routing, masking and priorities* on page D1-2316.

If an unmasked External Debug Request debug event was pending but is changed to not pending before it is taken, then the architecture permits the External Debug Request debug event to be taken, but does not require this to happen. If the External Debug Request debug event is taken then it must be taken before the first *Context synchronization event* after the External Debug Request debug event was changed to not pending.

Example H3-3 shows an example of the synchronization requirements.

Example H3-3 Synchronization requirements

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if **DBGEN** or **SPIDEN** or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

H3.5.2 Pseudocode description of External Debug Request debug events

The `ExternalDebugRequest()` function is described in Chapter J1 *Armv8 Pseudocode*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

H3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when enabled and the state of the OS Lock changes from locked to unlocked. When ARMv8.3-DoPD is implemented, CTIDEVCTL.OSUCE enables an OS Unlock Catch debug event, otherwise EDECR.OSUCE enables an OS Unlock Catch debug event.

When the OS Lock is unlocked, the PE sets EDESR.OSUC to 1 if the OS Unlock Catch debug event is enabled, and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. However, this is an indirect write to EDESR.OSUC, meaning the OS Unlock Catch debug event is not guaranteed to be taken before a subsequent Context synchronization event. If the PE enters Debug state or the OS Unlock Catch debug event is disabled before EDESR.OSUC becomes set to 1, then EDESR.OSUC might not be set.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also *Synchronization and Halting debug events* on page H3-6765.

EDESR.OSUC is cleared to 0 on a Warm reset and on exiting Debug state.

H3.6.1 Using the OS Unlock Catch debug event

If the debugger attempts to access a debug register when the Core power down domain is completely off or in a low-power state in which the Core power domain registers cannot be accessed, and that access returns an error, then the debugger must retry the access. However, if the Core power domain is regularly powered down, this can lead to unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in *Debug OS Save and Restore sequences* on page H6-6813, then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

H3.6.2 Pseudocode description of OS Unlock Catch debug event

The `CheckOSUnlockCatch()` function is called when the OS Lock is unlocked.

The `CheckPendingOSUnlockCatch()` function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H3.7 Reset Catch debug events

A Reset Catch debug event is generated when enabled, and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting EDESR.RC to 1. When ARMv8.3-DoPD is implemented, CTIDEVCTL.RCE enables a Reset Catch debug event, otherwise EDECR.RCE enables a Reset Catch debug event

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, DLR has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See *Synchronization and Halting debug events* on page H3-6765 for more information.

This means that EDESR.RC is set to the value of EDECR.RCE or CTIDEVCTL.RCE on a Warm reset. EDESR.RC is cleared to 0 on exiting Debug state.

H3.7.1 Pseudocode description of Reset Catch debug event

The `CheckResetCatch()` function is called after reset before executing any instruction.

The `CheckPendingResetCatch()` function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

Non-Confidential

H3.8 Software Access debug event

When the value of EDSCR.TDA is 1, software access to the following AArch64 and AArch32 debug System registers generate a Software Access debug event:

- The Breakpoint Value Registers, DBGBVR.
- The Breakpoint Control Registers, DBGBCR.
- The Watchpoint Value Registers, DBGWVR.
- The Watchpoint Control Registers, DBGWCR.

However, EDSCR.TDA is ignored if any of the following applies:

- The value of OSLSR.OSLK == 1, meaning that the OS Lock is locked.
- Halting is prohibited. See *Halting allowed and halting prohibited* on page H2-6705.
- The register access generates an exception.

Note

- The only accesses to the specified registers that generate a Software Access debug event are:
  - Accesses to System registers in AArch64 state.
  - Accesses to System registers in the (`coproc==0b1110`) encoding space in AArch32 state.
- Accesses by a PE using the external debug interface never generate a Software Access debug event.

H3.8.1 Pseudocode description of Software Access debug event

The `CheckSoftwareAccessToDebugRegisters()` function is described in Chapter J1 *Armv8 Pseudocode*.

H3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.
- The state of the external authentication interface.

For some registers, all read and write accesses that update the register occur in program order, without any additional synchronization, but others require an explicit *Context synchronization event*. For more information on the synchronization of register updates see:

- *Synchronization requirements for AArch64 System registers* on page D13-2819.
- *Synchronization of changes to the external debug registers* on page H8-6828.
- *State and mode changes without explicit context synchronization events* on page G2-5674.

Changes to the external authentication interface do not require explicit synchronization to affect External Debug Request debug events. See *Synchronization and External Debug Request debug events* on page H3-6761.

For changes that require explicit synchronization, it is CONSTRAINED UNPREDICTABLE whether instructions between the change and the *Context synchronization event* observe the old state or the new state.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a *Context synchronization event* before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Breakpoint and Watchpoint debug events. See *Synchronization and debug exceptions* on page D2-2459 for exceptions taken from AArch64 state, or *Synchronization and debug exceptions* on page G2-5674 for exceptions taken from AArch32 state.
- The generation of all Halting debug events by instructions.
- Taking a pending Halting debug event or other asynchronous Debug event. See:
  - *Pending Halting debug events*.
  - *Synchronization and External Debug Request debug events* on page H3-6761.
- The behavior of the Halting Step state machine. See *Synchronization and the Halting Step state machine* on page H3-6752.

H3.9.1 Pending Halting debug events

A Halting debug event might be pending:

1. If Halting Step of an instruction sets EDESR.SS is set to 1, and halting is prohibited following the step, then the Halting Step state machine is inactive but a Halting Step debug event is pending.
2. If a Reset Catch debug event sets EDESR.RC to 1, and halting is prohibited following reset, then a Reset Catch debug event is pending.
3. If an OS Unlock Catch debug event sets EDESR.OSUC to 1, then an OS Unlock Catch debug event is pending.

Pending Halting debug events are taken asynchronously when halting is allowed.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to EDESR.

Any Halting debug event that is observed as pending in the EDESR before a *Context synchronization event* is taken and the PE enters Debug state before the first instruction following the *Context synchronization event* completes its execution. This is only possible if halting is allowed after completion of the *Context synchronization event*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the first instruction after the *Context synchronization event* generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless both:

- A Halting Step debug event is pending. EDESR.SS == 1.
- The *Context synchronization event* is an exception return from a state where halting is prohibited to a state where halting is allowed.

  Note

  This applies to an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.

In this case the order in which the debug events are handled is specified to avoid a double-step. See *Entering the active-pending state* on page H3-6751.

If an asynchronous exception is also pending after the *Context synchronization event* then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

Note

These rules are based on the rules that apply to taking asynchronous exceptions. See *Asynchronous exception types, routing, masking and priorities* on page D1-2316.

Chapter H4
The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the *Debug Communications Channel* (DCC) and the *Instruction Transfer Register* (ITR), and associated control flags. It contains the following sections:

- *Introduction* on page H4-6768.
- *DCC and ITR registers* on page H4-6769.
- *DCC and ITR access modes* on page H4-6772.
- *Flow control of the DCC and ITR registers* on page H4-6776.
- *Synchronization of DCC and ITR accesses* on page H4-6780.
- *Interrupt-driven use of the DCC* on page H4-6786.
- *Pseudocode description of the operation of the DCC and ITR registers* on page H4-6787.

Note

Where necessary Table K14-1 on page K14-7810 disambiguates the general register references used in this chapter.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H4.1 Introduction

The *Debug Communications Channe*l, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

- An external debugger, described as the *debug host*.
- The debug implementation on the PE, described as the *debug target*.

The DCC can be used:

- As a 32-bit full-duplex channel.
- As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H4.2 DCC and ITR registers

The DCC comprises *data transfer registers*, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, EDITR, and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
  - The write-only DBGDTRTX_EL0 register to transmit data.
  - The read-only DBGDTRRX_EL0 register to receive data.
- A single 64-bit read/write register, DBGDTR_EL0, for 64-bit half-duplex operation.
- The read/write OSDTRTX_EL1 and OSDTRRX_EL1 registers for save and restore.

In AArch32 state, software can only access the data transfer registers as:

- A receive and transmit pair, for 32-bit full duplex operation:
  - The write-only DBGDTRTXint register to transmit data.
  - The read-only DBGDTRRXint register to receive data.
- The read/write DBGDTRTXext and DBGDTRRXext registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, DBGDTRRX_EL0 and DBGDTRTX_EL0. Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are EDSCR.{RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the Debug system registers in DCCSR.
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in DSCR.
- The flow-control flags are accessible from the external debug interface in EDSCR.

Figure H4-1 on page H4-6770 shows the System register and external debug interface views of the EDSCR and DTR registers in both AArch64 state and AArch32 state. These figures do not include the save and restore views.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

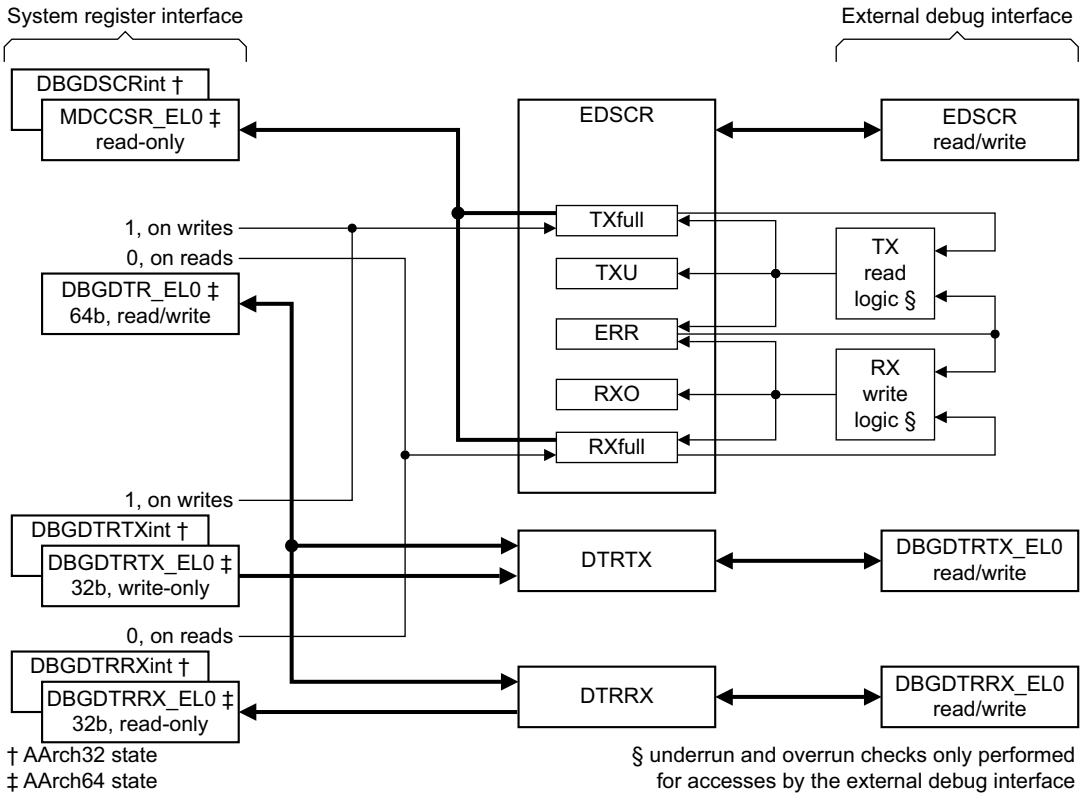

Figure H4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode

EDITR and the ITR flow-control flags, EDSCR.{ITE, ITO} are accessible only by the external debug interface:

- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

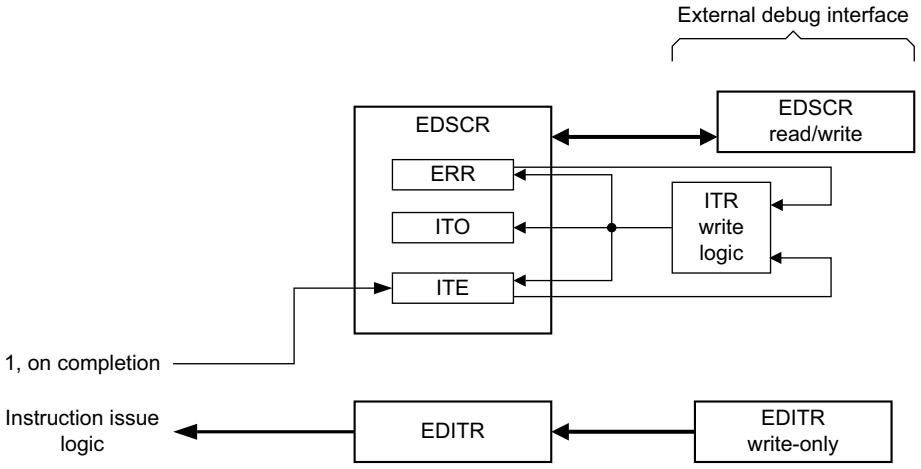

Figure H4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.

To save and restore the DCC registers for an external debugger over powerdown, software uses:

- The MDSCR_EL1, OSDTRTX_EL1, and OSDTRRX_EL1 registers in AArch64 state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The DBGDSCRext, DBGDTRTXext, and DBGDTRRXext registers in AArch32 state.

Note

There is no save and restore mechanism for the ITR registers as the ITR is only used in Debug state.

H4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

DCC and ITR access mode, links to description	Applies when:
Normal access mode	EDSCR.MA == 0 or the PE is in Non-debug state
Memory access mode on page H4-6773	EDSCR.MA == 1 and the PE is in Debug state

H4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

For accesses by software:

- Direct writes to DBGDTRTX update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from DBGDTRRX return the value in DTRRX and indirectly write 0 to RXfull.
- In AArch64 state, direct writes to DBGDTR_EL0 update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
  - DTRTX is set from bits[31:0] of the transfer register.
  - DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from DBGDTR_EL0 return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
  - Bits[31:0] of the transfer register are set from DTRRX.
  - Bits[63:32] of the transfer register are set from DTRTX.

Note

For DBGDTR_EL0, the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using DCCSR.

For accesses by the external debug interface:

- Writes to EDITR trigger the instruction to be executed if the PE is in Debug state:
  - If the PE is in AArch64 state, this is an A64 instruction.
  - If the PE is in AArch32 state, this is a T32 instruction. The T32 instruction is a pair of halfwords where the first halfword is taken from the lower 16-bits, and the second halfword is taken from the upper 16-bits.
- Reads of DBGDTRTX_EL0 return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to DBGDTRTX_EL0 update the value in DTRTX and do not change TXfull.
- Reads of DBGDTRRX_EL0 return the value in DTRRX and do not change RXfull.
- Writes to DBGDTRRX_EL0 update the value in DTRRX and indirectly write 1 to RXfull.

TXfull and RXfull are visible to the external debug interface in EDSCR.

The PE detects overrun and underrun by the external debug interface, and records errors in EDSCR.{TXU, RXO, ITO, ERR}. See *Flow control of the DCC and ITR registers* on page H4-6776.

See also *Synchronization of DCC and ITR accesses* on page H4-6780.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H4.3.2 Memory access mode

When the PE is in Debug state, *Memory access mode* can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can only be enabled in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- External reads from DBGDTRTX_EL0 cause:
  1. The existing value in DTRTX to be returned. This clears EDSCR.TXfull to 0.
  2. The equivalent of `LDR W1,[X0],#4`, if in AArch64 state, or `LDR R1,[R0],#4`, if in AArch32 state, to be executed.
  3. The equivalent of the `MSR DBGDTRTX_EL0,X1` instruction, if in AArch64 state, or the `MCR p14,0,R1,c0,c5,0` instruction, if in AArch32 state, to be executed.
  4. EDSCR.{TXfull, ITE} to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.
- External writes to DBGDTRRX_EL0 cause:
  1. The value in DTRRX to be updated. This sets EDSCR.RXfull to 1.
  2. The equivalent of the instruction `MRS X1,DBGDTRRX_EL0`, if in AArch64 state, or `MRC p14,0,R1,c0,c5,0` if in AArch32 state, to be executed.
  3. The equivalent of the instruction `STR W1,[X0],#4`, if in AArch64 state, or `STR R1,[R0],#4`, if in AArch32 state, to be executed.
  4. EDSCR.{RXfull, ITE} to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.
- External reads from DBGDTRRX_EL0 return the last value written to DTRRX.
- External writes to EDITR generate an overrun error.

During these accesses, EDSCR.{TXfull, RXfull, ITE} are used for flow control.

Note

An overrun or underrun might result in EDSCR.ERR being set to 1 asynchronously to the sequence of operations that are outlined in this section. As this is timing-dependent, it is UNPREDICTABLE when the EDSCR.ERR flag affects the instructions and therefore whether neither instruction, only the first instruction, or both instructions are executed. If the second instruction is executed, then the first instruction must have been executed. However, in each case X1 or R1 is set to an UNKNOWN value. This means that:

- In both cases, if the memory access instruction is not executed, then the base register X0 or R0 is not updated, meaning the debugger can determine the last accessed location.
- In the list describing External reads from DBGDTRTX_EL0, DTRTX and EDSCR.TXfull get set to UNKNOWN values. If the load was executed, then the value that was read by the PE is lost. This means the operation might need to be repeated by the debugger, and it is not advisable to use Memory access mode to read from read-sensitive locations using the underrun and overrun detection for flow control.
- In the list describing External writes to DBGDTRRX_EL0, EDSCR.RXfull is set to an UNKNOWN value.

A Data Abort from the memory access can also set EDSCR.ERR to 1. See *Data Aborts in Memory access mode* on page H4-6774.

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to DBGDTRRX_EL0, in AArch64 state, RXfull might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and re-order instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing *External reads from DBGDTRTX_EL0* on page H4-6773:
  - The `MSR` equivalent operation at step 3 of the sequence reads the value loaded by step 2.
  - If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the `MSR` equivalent operation at the previous iteration of step 3.
- In the list describing *External writes to DBGDTRRX_EL0* on page H4-6773:
  - The `MRS` equivalent operation at step 2 of the sequence returns the value written at step 1.
  - The `STR` equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun.

See *Flow control of the DCC and ITR registers* on page H4-6776 for more information on overrun and underrun.

Ordering, access sizes and effect on Exclusives monitors

For the purposes of memory ordering, access sizes, and effect on the Exclusives monitor, accesses in Memory access mode are consistent with Load/Store word instructions executed by the PE.

The simple sequential access model of Memory-access mode, as stated in *Memory access mode* on page H4-6773, must also be ordered with respect to instructions executed as a result of explicit writes to EDITR in Normal mode both before and after accesses to the DTR registers in Memory-access mode.

Data Aborts in Memory access mode

If a memory access generates a Data Abort, then:

- The Data Abort exception is taken. See *Exceptions in Debug state* on page H2-6734:
  - This means EDSCR.ERR is set to 1, see *Cumulative error flag* on page H4-6778.
  - If the Data Abort occurs on stage 2 of an address translation, then the values returned in the ISV field and in bits[23:14] of the ISS are UNKNOWN.

    If this Data Abort is taken to EL2 using AArch64, the ISS is returned by ESR_EL2. *ISS encoding for an exception from a Data Abort* on page D13-2943 describes the usual encoding of this ISS.

    If EL2 is using AArch32 and this Data Abort is taken to Hyp mode, the ISS is returned by HSR. *ISS encoding for an exception from a Data Abort* on page G8-6099 describes the usual encoding of this ISS.
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- EDSCR.TXfull, for a load, or EDSCR.RXfull, for a store, is set to an UNKNOWN value.
- DTRTX, for a load, or DTRRX, for a store, is set to an UNKNOWN value.
- EDSCR.ITE is set to 1.

Illegal Execution state exception

If PSTATE.IL is set to 1 when EDSCR.MA == 1, then on an external write access to DBGDTRRX_EL0 or an external read from DBGDTRTX_EL0, it is CONSTRAINED UNPREDICTABLE whether the PE:

- Takes an Illegal Execution state exception without performing any operations. In this case:
  - EDSCR.ERR is set to 1, see *Cumulative error flag* on page H4-6778.
  - Register R0 is unchanged.
  - Register R1 is set to an UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - EDSCR.TXfull or EDSCR.RXfull, as applicable, is set to an UNKNOWN value.
  - DTRTX or DTRRX, as applicable, is set an UNKNOWN value.
  - EDSCR.ITE is set to 1.

  See also *Exceptions in Debug state* on page H2-6734.
- Ignores PSTATE.IL.

Note

The typical usage model for Memory access mode involves executing instructions in Normal access mode to set up X0 before setting EDSCR.MA to 1. These instructions generate an Illegal state exception if PSTATE.IL is set to 1.

Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
  2. The PE makes a memory access to `Align(X[0],4)` in AArch64 state, or `Align(R[0],4)` in AArch32 state.
  3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
  4. The PE does nothing.
- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.
- For external writes to DBGDTRRX_EL0, if the PE writes to memory, an UNKNOWN value is written.
- For external reads of DBGDTRTX_EL0 an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a DBGDTRTX_EL0 read can trigger a TX underrun, and a DBGDTRTX_EL0 write can trigger an RX overrun.

H4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in EDSCR by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see *Register access permissions for memory-mapped accesses* on page H8-6832.

H4.4 Flow control of the DCC and ITR registers

- *Ready flags*.
- *Buffering writes to EDITR*.
- *Overrun and underrun flags*.
- *Cumulative error flag* on page H4-6778.

H4.4.1 Ready flags

In Normal access mode:

- For the DTR registers there are two ready flags:
  - EDSCR.RXfull == 1 indicates that DBGDTRRX_EL0 contains a valid value that has been written by the external debugger and not yet read by software running on the target.
  - EDSCR.TXfull == 1 indicates that DBGDTRTX_EL0 contains a valid value that has been written by software running on the target and not yet read by an external debugger.
- For the ITR register there is a single ready flag:
  - EDSCR.ITE == 1 indicates that the PE is ready to accept an instruction to the ITR.

    Note

    The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if EDSCR.ERR is set, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- EDSCR.{RXfull, ITE} == {0,1} indicates that DBGDTRRX_EL0 is empty and the PE is ready to accept a word external write to DBGDTRRX_EL0.
- EDSCR.{TXfull, ITE} == {1,1} indicates that DBGDTRTX_EL0 is full and the PE is ready to accept a word external read from DBGDTRTX_EL0.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in *Overrun and underrun flags*.

EDSCR.{ITE, RXfull, TXfull} shows the status of the ITR and DCC registers. It ignores the question of whether a read or write cannot be accepted because, for example, EDSCR.ERR is set or the OPTIONAL Software Lock is locked for memory-mapped accesses (EDLSR.SLK == 1).

H4.4.2 Buffering writes to EDITR

The architecture permits a processor to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, provided that:

- Those instructions are discarded if EDSCR.ERR is set to 1, either by an underrun or an overrun, or by any other error conditions described in this architecture, such as an instruction generating an abort.
- The PE maintains the simple sequential execution model with the order of instructions determined by the order in which the PE accepts the EDITR writes. In particular, the buffered instructions must be executed in the Execution state consistent with a simple sequential execution of the instructions, even if one of the previous instructions is a state changing operation, such as `DCPS` or `DRPS`.

H4.4.3 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to EDRCR.CSE.

Note

The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

Table H4-1 shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

Table H4-1 DCC and ITR ready flags and the associated overrun/underrun flags

External debug interface access	Overrun/Underrun condition	EDSCR flag
Write DBGDTRRX_EL0	`EDSCR.RXfull == '1' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	RXO
Read DBGDTRTX_EL0	`EDSCR.TXfull == '0' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	TXU
Write EDITR	`Halted() && (EDSCR.ITE == '0' || EDSCR.MA == '1')`	ITO

When an overrun or underrun flag is set to 1, the cumulative error flag, EDSCR.ERR, described in *Cumulative error flag* on page H4-6778, is also set to 1.

In the event of an external write to DBGDTRRX_EL0 or EDITR generating an overrun, or an external read from DBGDTRTX_EL0 generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- EDSCR.TXfull, EDSCR.RXfull or EDSCR.ITE, as applicable, are not updated.

There is no overrun or underrun detection on external reads of DBGDTRRX_EL0 or external writes of DBGDTRTX_EL0.

There is no overrun or underrun detection of direct reads and direct writes of the DTR System registers by software:

- If RXfull == 0, a direct read of DBGDTRRX or DBGDTR_EL0 returns UNKNOWN.
- If TXfull == 1, a direct write of:
  - DBGDTRTX sets DTRTX to UNKNOWN.
  - DBGDTR_EL0 sets DTRRX and DTRTX to UNKNOWN.

See *DCC accesses in Non-debug state* on page H4-6781 for more information.

Accessing 64-bit data

In AArch64 state, a software access to the DBGDTR_EL0 register and an external debugger access to both DBGDTRRX_EL0 and DBGDTRTX_EL0 can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to DBGDTR_EL0, only TXfull is set to 1, meaning:
  - A subsequent external write to DBGDTRRX_EL0 would not be detected as an overrun.
  - If the external debugger reads DBGDTRTX_EL0 first, software might observe MDCCSR_EL0.TXfull == 0 and send a second value before the external debugger reads DBGDTRRX_EL0, leading to an undetected overrun.
- On external writes to both DBGDTRRX_EL0 and DBGDTRTX_EL0 only RXfull is set to 1, meaning:
  - A subsequent direct write of DBGDTRTX_EL0 would not be detected as an overrun.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If the external debugger writes to DBGDTRRX_EL0 first, software might observe MDCCSR_EL0.RXfull == 1 and read a full 64-bit value, before the external debugger writes to DBGDTRTX_EL0, leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check EDSCR.{RXfull, TXfull} before each transfer.
- To receive a 64-bit value from the target, the external debugger must read DBGDTRRX_EL0 before reading DBGDTRTX_EL0.
- To send a 64-bit value to the target, the external debugger must write to DBGDTRTX_EL0 before writing DBGDTRRX_EL0.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

H4.4.4 Cumulative error flag

The cumulative error flag, EDSCR.ERR, is set to 1:

- On taking an exception from Debug state.
- On any signalled overrun or underrun in the DCC or ITR.

When EDSCR.ERR == 1:

- External reads of DBGDTRTX_EL0 do not have any side-effects.
- External writes to DBGDTRRX_EL0 are ignored.
- External writes to EDITR are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to EDITR that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check EDSCR.{RXfull, TXfull, ITE} before each access.
- Check EDSCR.{ITO, RXO, TXU} following each access, for overrun or underrun.
- Check PSTATE or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared to 0 by writing 1 to EDRCR.CSE. However, the effect of writing 1 to EDRCR.CSE to clear EDSCR.ERR is CONSTRAINED UNPREDICTABLE when both of the following apply:

- The PE is in Debug state.
- The value of EDSCR.ITE is 0.

When these conditions apply and a value of 1 is written to EDRCR.CSE, either or both of the following might occur:

- EDSCR.ERR is not cleared to 0.
- Any instructions in EDITR that have not been executed might be executed subsequently, rather than being ignored.

Note

This means that a debugger must poll EDSCR.ITE until it has the value 1, indicating that EDITR is empty, before writing to EDRCR.CSE to clear the EDSCR.ERR flag to 0.

For overruns and underruns, EDSCR.{ITO, RXO, TXU} record the error type.

H4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- *Summary of System register accesses to the DCC*.
- *DCC accesses in Non-debug state* on page H4-6781.
- *Synchronization of DCC interrupt request signals* on page H4-6784.
- *DCC and ITR access in Debug state* on page H4-6784.

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to System registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

Note

In *Synchronization requirements for AArch64 System registers* on page D13-2819 external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to DBGDTRRX_EL0 and DBGDTRTX_EL0 are asynchronous to direct reads of, and direct writes to, DBGDTRRX, DBGDTRTX, and in AArch64 state DBGDTR_EL0, made by software using System register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

Throughout this section:

DCC flags Means any or all of the following:
- The EDSCR.{RXfull.TXfull} ready flags.
- The EDSCR.RXO overrun flag.
- The EDSCR.TXU underrun flag.
- The EDSCR.ERR cumulative error flag.

ITR flags Means any or all of the following:
- The EDSCR.ITE ready flag.
- The EDSCR.ITO overrun flag.
- The EDSCR.ERR cumulative error flag.

H4.5.1 Summary of System register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in Table H4-2 on page H4-6781. Several of these instructions access the same registers using different encodings.

With the exception of the read and write bits, DBGDTRRX and DBGDTRTX are the same encoding, with exception of the read/write bits, but use different registers. The Armv8 architecture governs the order of these instructions, as described in *Synchronization requirements for AArch64 System registers* on page D13-2819. For more details, see the description of the individual register in the relevant chapter, Chapter D13 *AArch64 System Register Descriptions* or Chapter G8 *AArch32 System Register Descriptions*.

Table H4-2 shows a summary of System register accesses to the DCC.

Table H4-2 Summary of System register accesses to the DCC

Operation	OS Lock	AArch64 (MRS/MSR)	AArch32 (MRC/MCR)	Description
Read	-	DBGDTRRX_EL0	DBGDTRRXint	Direct read of DTRRX Indirect write to the DCC flags An STC instruction that reads DBGDTRRXint makes an indirect write to DBGDSCRint.RXfull
Write	-	DBGDTRTX_EL0	DBGDTRTXint	Direct read of DTRTX Indirect write to the DCC flags An LDC instruction that writes to DBGDTRTXint using a value read from memory is a direct write to DBGDTRTXint
Read/write	-	DBGDTR_EL0	-	Direct read/write of both DTRRX and DTRTX Indirect write to the DCC flags
Read	-	MDCCSR_EL0	DBGDSCRint	Direct read of the DCC flags
Read/write	-	OSDTRRX_EL1	DBGDTRRXext	Direct read/write of DTRRX
Read/write	-	OSDTRTX_EL1	DBGDTRTXext	Direct read/write of DTRTX
Read	Unlocked	MDSCR_EL1	DBGDSCRext	Direct read of DCC flags
Read/write	Locked	MDSCR_EL1	DBGDSCRext	Direct read/write of DCC flags

H4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in *Normal access mode* on page H4-6772:

- If a direct read of DCCSR returns RXfull == 1, then a following direct read of DBGDTRRX, or in AArch64 state of DBGDTR_EL0, returns valid data and indirectly writes 0 to DCCSR.RXfull as a side-effect.
- If a direct read of DCCSR returns TXfull == 0, then a following direct write to DBGDTRTX, or in AArch64 state to DBGDTR_EL0, writes the intended value, and indirectly writes 1 to DCCSR.TXfull as a side-effect.

No *Context synchronization event* is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the DCC flags as part of the DTR access instruction is made atomically with the DTR access.

Because a direct read of DBGDTRRX is an indirect write to DCCSR.RXfull, it must occur in program order with respect to the direct read of DCCSR, meaning it must not return a speculative value for DTTRX that predates the RXfull flag returned by the read of DCCSR. The direct write to DBGDTRTX must not be executed speculatively.

Direct reads of DBGDTRRX, or in AArch64 state DBGDTR_EL0, and DCCSR, must occur in program order with respect to other direct reads of the same register using the same encoding.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the DCC flags occurs immediately after the direct DTR access.

  Note

  For an access to DBGDTR_EL0, this means the indirect write happens after both DBGDTRRX_EL0 and DBGDTRTX_EL0 have been accessed.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In the simple sequential execution model, for an external read of DBGDTRTX_EL0 or an external write of DBGDTRRX_EL0:
  - The check of the DCC flags for overrun or underrun occurs immediately before the access.
  - If there is no underrun or overrun, the update of the DCC flags occurs immediately after the access.
  - If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

All observers must observe the same order for accesses.

Note

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to DBGDTRRX_EL0 that does not overrun, must be observable to direct reads of DBGDTRRX and DBGDTR_EL0 in finite time.
- The DCC flags that are updated as a side-effect of the external write or external read must be observable:
  - To subsequent external reads of EDSCR.
  - To subsequent external reads of DBGDTRRX_EL0 when checking for underrun.
  - To subsequent external writes to DBGDTRTX_EL0 when checking for overrun.
  - To direct reads of DCCSR in finite time.

However, explicit synchronization is required to guarantee that a direct read of DCCSR returns up-to-date DCC flags. This means that if a signal is received from another agent that indicates that DCCSR must be read, an `ISB` is required to ensure that the direct read of DCCSR occurs after the signal has been received. This also synchronizes the value in DBGDTRRX, if applicable. However, if that signal is an interrupt exception triggered by **COMMIRQ**, **COMMTX**, or **COMMRX**, the exception entry is sufficient synchronization. See *Synchronization of DCC interrupt request signals* on page H4-6784.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to DBGDTRTX is observable to external reads of DBGDTRTX_EL0.
- To ensure that a value directly written to DBGDTR_EL0 is observable to external reads of DBGDTRTX_EL0 and DBGDTRRX_EL0.
- To guarantee that the indirect writes to the DCC flags that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
  - Observable to external reads of EDSCR.
  - Observable to external reads of DBGDTRRX_EL0 when checking for underrun.
  - Observable to external writes of DBGDTRTX_EL0 when checking for overrun.
  - Returned by a following direct read of DCCSR.

See also *Memory-mapped accesses to the DCC and ITR* on page H4-6775 and *Synchronization of changes to the external debug registers* on page H8-6828.

Note

These ordering rules mean that software:

- Must not read DBGDTRRX without first checking DCCSR.RXfull or if the previously-read value of DCCSR.RXfull is 0.

  It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.

- Must not write DBGDTRTX without first checking DCCSR.TXfull or if the previously-read value of DCCSR.TXfull is 1.

  The write to DBGDTRTX overwrites the value in DTRTX, and the external debugger might or might not have read this value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Must ensure there is an explicit *Context synchronization event* following a DTR access, even if not immediately returning to read DCCSR again. This synchronization operation can be an exception return.

Derived requirements

The rules for DCC accesses in Non-debug state are as follows:

- Following a direct read of DBGDTRRX when RXfull is 1:
  - If an external write to DBGDTRRX checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write.
  - If an external read of EDSCR returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by a following external write to DBGDTRRX, and the following external write does not overrun.
- Following a direct read of DBGDTR_EL0, when RXfull is 1:
  - If an external write to DBGDTRRX checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write nor by a following direct write to DBGDTRTX.
  - If an external read of EDSCR returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by subsequent external writes to DBGDTRRX and DBGDTRTX in any order, and the following external write of DBGDTRRX will not overrun.
- Following a direct write to DBGDTRTX, when TXfull is 0:
  - If an external read of DBGDTRTX checks the TXfull flag for underrun and observes that the value of TXfull is 1, the value returned by the external read must be the value written by the previous direct write.
  - If an external read of EDSCR returns a TXfull value of 1, then the value returned by a following external read of DBGDTRRX must be the value written by the previous direct read, and the subsequent external read will not underrun.
- Following a direct write to DBGDTR_EL0, when TXfull is 0:
  - If an external read of DBGDTRTX checks the TXfull flag for underrun and observes that the value of TXfull is 1, the values returned by the external read and by a subsequent external read of DBGDTRRX must be the value written by the previous direct write.
  - If an external read of EDSCR returns a TXfull value of 1, then the value returned by subsequent external reads of DBGDTRRX and DBGDTRTX, in any order, must be the value written by the previous direct read, and the subsequent external read of DBGDTRTX does not underrun.
- Following an external read of DBGDTRTX that does not underrun, if a direct read of DCCSR returns a TXfull value of 0, then the value returned by the external read must not be affected by a following direct write to DBGDTRTX.
- Following a first external read DBGDTRRX and a following second external read of DBGDTRTX that does not underrun, if a direct read of DCCSR returns a TXfull value of 0, then the values returned by the external reads must not be affected by a following direct write to DBGDTR_EL0.
- Following an external write to DBGDTRRX that does not overrun, if a direct read of DCCSR returns an RXfull value of 1, then the value returned by a following direct read of DBGDTRRX or DBGDTR_EL0 must be the value written by the previous external write.
- Following a first external write to DBGDTRTX and a following second external write to DBGDTRRX that does not overrun, if a direct read of DCCSR returns an RXfull value of 1, then the value returned by a subsequent direct read of DBGDTR_EL0 must return the values written by the previous external writes.

H4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, **COMMIRQ**, **COMMTX**, and **COMMRX**, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of DCCSR or DBGDTRRX, or a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request.

Note

The requirement that indirect writes to registers are observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time. For more information, see *Synchronization requirements for AArch64 System registers* on page D13-2819 and *Synchronization of changes to AArch32 System registers* on page G8-5896.

Following a direct read of DBGDTRRX or a direct write to DBGDTRRX, software must execute a *Context synchronization event* to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

H4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal access mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to EDITR must be observable to an external write or an external read in finite time:
  - A direct read of DBGDTRRX must be observable to an external write of DBGDTRRX_EL0.
  - A direct read of DBGDTR_EL0 must be observable to an external write of DBGDTRRX_EL0 and DBGDTRTX_EL0.
  - A direct write of DBGDTRTX must be observable to an external read of DBGDTRTX_EL0.
  - A direct write of DBGDTR_EL0 must be observable to an external read of DBGDTRRX_EL0 and DBGDTRTX_EL0.

  This includes the indirect write to the DCC flags that occurs atomically with the access as described in *DCC accesses in Non-debug state* on page H4-6781.

  The subsequent external write or external read must observe either the old or the new values of both the DTR contents and DCC flags. If the old values are observed, this typically results in overrun or underrun, assuming the old values of the DCC flags indicate an overrun or underrun condition, as would normally be the case.

  This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the DCC flags in EDSCR, because it can rely on overrun and underrun tests.
- External reads of DBGDTRTX_EL0 that do not underrun and external writes to DBGDTRRX_EL0 that do not overrun must be observable to an instruction subsequently written to EDITR on completion of the first external access. This includes the indirect write to the DCC flags.

  This means that without explicit synchronization and without the need to first check the DCC flags in DCCSR:
  - If the instruction is a direct read of DBGDTRRX, it observes the external write.
  - If the instruction is a direct write of DBGDTRTX, it observes the external read.
- Writes to EDITR that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.
- After an external write to the EDITR, the ITR flags that are updated as a side effect of that write must be observable by:
  - An external read of the EDSCR that follows the external write to the EDITR.
  - When checking for overrun, another external write to the EDITR that follows the original external write to the EDITR.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in *Memory access mode* on page H4-6773.

H4.6 Interrupt-driven use of the DCC

Arm recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a private peripheral interrupt for the originating PE.

Note

- In addition to connection to the interrupt controller Arm also recommends **COMMIRQ**, **COMMTX**, and **COMMRX** signals that might be implemented for use by any legacy system peripherals.
- GICv3 reserves a private peripheral interrupt number for the **COMMIRQ** interrupt.

The DCCINT register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, **COMMIRQ**, is needed at the interrupt controller.

See also *Synchronization of DCC interrupt request signals* on page H4-6784.

Non-Confidential

H4.7 Pseudocode description of the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when OSLSR.OSLK == 1, meaning that the OS Lock is locked:

- `DBGDTR_EL0[]`.
- `DBGDTRRX_EL0[]`.
- `DBGDTRTX_EL0[]`.
- `EDITR[]`.
- `CheckForDCCInterrupts()`.

For the definition of the DTR Registers, see *shared/debug/dccanditr/DTR* on page J1-7500.

Chapter H5
The Embedded Cross-Trigger Interface

This chapter describes the embedded cross-trigger interface. It contains the following sections:

- *About the Embedded Cross-Trigger (ECT)* on page H5-6790.
- *Basic operation on the ECT* on page H5-6792.
- *Cross-triggers on a PE in an Armv8 implementation* on page H5-6796.
- *Description and allocation of CTI triggers* on page H5-6797.
- *CTI registers programmers' model* on page H5-6801.
- *Examples* on page H5-6802.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H5.1 About the Embedded Cross-Trigger (ECT)

The *Embedded Cross-Trigger*, ECT, allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs, or other system components, when a trigger event occurs on another PE or system component. For example, this might be done to halt all PEs when one individual PE halts.

Figure H5-1 shows the logical structure of an ECT.

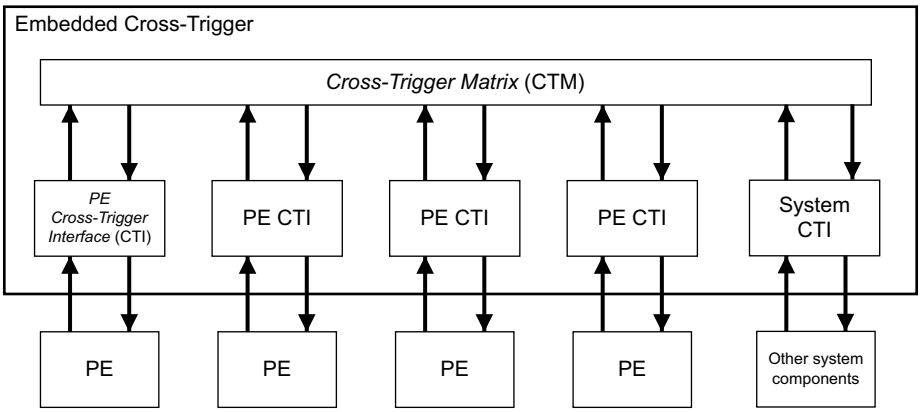

Figure H5-1 Structure of an embedded cross-trigger

The ECT can deliver many types of trigger events, which are described in the following sections:

- *Debug request trigger event* on page H5-6797.
- *Restart request trigger event* on page H5-6798.
- *Cross-halt trigger event* on page H5-6798.
- *Performance Monitors overflow trigger event* on page H5-6798.
- *Generic trace external input trigger events* on page H5-6799.
- *Generic trace external output trigger events* on page H5-6799.
- *Generic CTI interrupt trigger event* on page H5-6799.

An Armv8-A implementation must:

- Include a cross-trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

In addition, see *Cross-triggers on a PE in an Armv8 implementation* on page H5-6796.

Arm recommends that this cross-trigger interface includes:

- The ability to route trigger events between Trace Units, which typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

Also, Arm recommends that the Embedded Cross-Trigger includes the capability to send and receive IMPLEMENTATION DEFINED system trigger events to and from other system components, including a system counter, using a system CTI. See *Halt-on-debug* on page I2-7018.

Note

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug sub-system to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

Non-Confidential

Note

CTI version 1 (CTIv1) is defined by the *CoreSight™ SoC Technical Reference Manual*. CTIv2 extends CTIv1 with the addition of the input channel gate see *Implementation with CTIv2*

H5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections in an Armv8-A implementation, see Appendix K2 *Recommended External Debug Interface*. See also *CoreSight™ SoC Technical Reference Manual.*

H5.1.2 Implementation with CTIv2

If the CTI implemented is CTIv2 then:

- The CTIDEVARCH, CTIDEVAFF0, and CTIDEVAFF1 registers must be implemented.
- If the channel gate function is implemented, it applies to both input and output channels.
- The input channel gate function must be implemented if either of the following is true:
  - The CTM is implemented and the architecture variant is Armv8.5 or higher.
  - The CTIDEVARCH,REVISION field reads as `0b0001`or higher.

Implementation of CTIv2 features in architecture variants below Armv8.5 is OPTIONAL, but Arm recommends that CTIv2 is implemented, CTIv2 must be implemented from Armv8.5.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The ECT might also include other CTIs for other system components. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the cross-trigger interface, CTI, are:

- The input triggers:
  - These are trigger event inputs from the PE to the CTI.
- The output triggers:
  - These are trigger event outputs from the CTI to the PE.
- The input channels:
  - These are channel event inputs from the cross-trigger matrix, CTM, to the CTI.
- The output channels:
  - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
  - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
  - The output triggers are numbered 0-31.

If the CTI is not powered up when the Core power domain is powered up, the CTI ignores all input triggers and input channel events, and does not generate any output triggers or output channel events.

Figure H5-2 on page H5-6793 shows the logical internal structure of a CTI.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

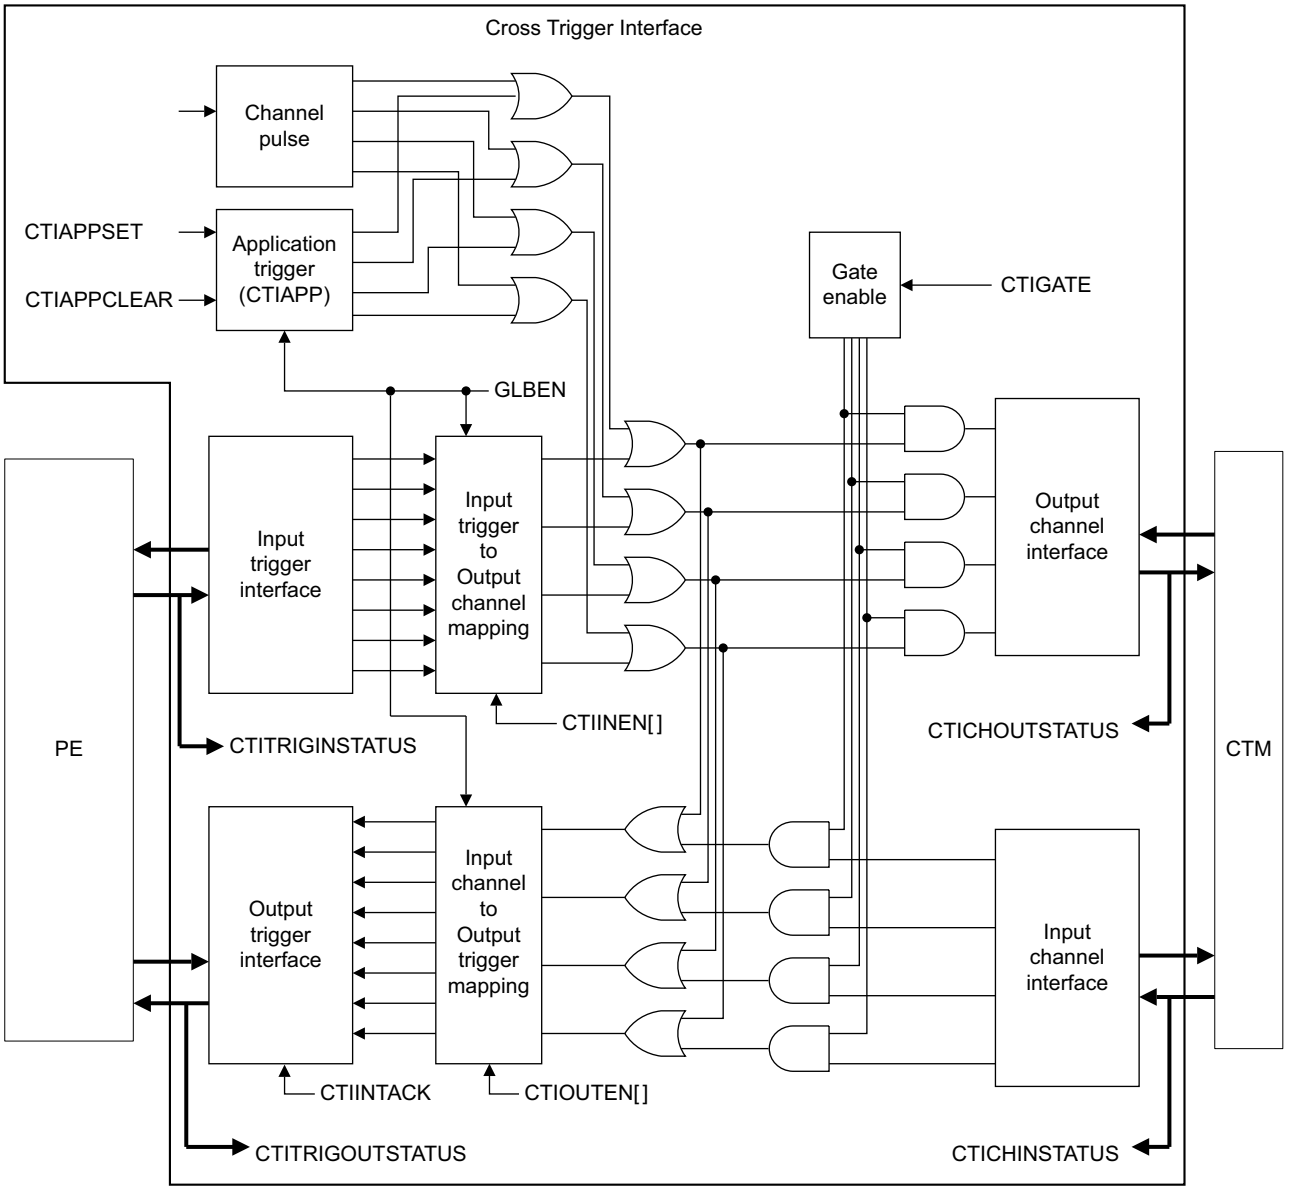

Figure H5-2 Structure of a cross-trigger interface

Note

- The number of triggers in IMPLEMENTATION DEFINED. Figure H5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure H5-2 shows four channels.
- In Figure H5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the *mapping function* defined by the *Input trigger→output channel mapping registers*, CTIINEN<n>.

The CTI also contains an *application trigger* and *channel pulse* to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Channel events on each internal channel are passed to a corresponding output channel that is controlled by a *channel gate*. The channel gate can block propagation of channel events from an internal channel to an output channel.

Note

If the CTM is implemented:

- The gate function must be implemented.
- If the CTI is CTIv1, the gate function applies to output triggers only.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the *cross-trigger matrix*, CTM. Therefore, the number of input channels must equal the number of output channels.

Note

The number of input triggers and output triggers is not required to be the same.

The internal channels form an internal cross-trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

Note

If CTIv2 is implemented, the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the *Input channel → output trigger mapping registers*, CTIOUTEN<n>.

The CTI contains the input and output trigger interfaces to the PE and the interface of the cross-trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See *Multicycle events* on page H5-6795.

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of CTIINTACK.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

Note

Arm recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

H5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

Note

A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.

An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

Note

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

CTIAPPSET and CTIAPPCLEAR can set a channel active for multiple cycles. CTIAPPPULSE generates a single channel event. CTICHINSTATUS and CTICHOUTSTATUS can report whether a channel is active.

An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

Note

A single event is typically a single cycle, but there is no guarantee that this is always the case.

CTIAPPSET and CTIAPPCLEAR can only generate a single channel event. CTIAPPPULSE generates a single channel event. If the ECT does not support multicycle channel events, use of CTIAPPSET and CTIAPPCLEAR is deprecated, and the debugger must only use CTIAPPPULSE. CTICHINSTATUS and CTICHOUTSTATUS must be treated as UNKNOWN.

H5.3 Cross-triggers on a PE in an Armv8 implementation

An Armv8 PE must include a cross-trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the cross-trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the Armv8-A PE, but can also connect to additional PEs. Arm strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes Armv7-A PEs and other PEs that can be connected using a CoreSight CTI module.

Note

In a uniprocessor system the CTM is OPTIONAL. In a multiprocessor system the CTM is required. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. Arm recommends that the CTM is implemented.

Any CTI connected to a PE that is not an Armv8-A PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the *CoreSight ™ SoC Technical Reference Manual*. Armv8-A refines the generic CTI by defining roles for each of the implemented input and output triggers.

Non-Confidential

H5.4 Description and allocation of CTI triggers

Table H5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

Table H5-1 Allocation of CTI output trigger events

Number	Source	Destination	Event description
0	CTI	PE	*Debug request trigger event*
1	CTI	PE	*Restart request trigger event* on page H5-6798
2	CTI	IRQ controller	*Generic CTI interrupt trigger event* on page H5-6799
3	-	-	Reserved
4 - 7	CTI	PE Trace Unit	OPTIONAL *Generic trace external input trigger events* on page H5-6799

Note

Output triggers from the CTI are inputs to other blocks.

Table H5-2 shows the input trigger events defined by the architecture and the related trigger numbers.

Table H5-2 Allocation of CTI input trigger events

Number	Source	Destination	Event description
0	PE	CTI	*Cross-halt trigger event* on page H5-6798
1	PE	CTI	*Performance Monitors overflow trigger event* on page H5-6798
2	PE	CTI	*Statistical Profiling Extension sample trigger event* on page H5-6799
3	-	-	Reserved
4 - 7	PE Trace Unit	CTI	OPTIONAL *Generic trace external output trigger events* on page H5-6799

Note

Input triggers to the CTI are outputs from other blocks.

Table H5-1 and Table H5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are only required if the OPTIONAL PE Trace Unit is implemented. If the OPTIONAL PE Trace Unit is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. Arm strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An Armv8-A implementation can extend the CTI with additional triggers. These start with the number eight.

H5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[0].

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

A debugger must poll CTITRIGOUTSTATUS[0] until it reads as 0, to confirm that the output trigger has been deasserted before generating any event that must be ordered after the write to CTIINTACK, such as a write to CTIAPPPULSE to activate another trigger.

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also *External Debug Request debug event* on page H3-6761.

H5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is in Non-debug state, the request is ignored by the PE.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONSTRAINED UNPREDICTABLE whether:

- The request is ignored by the PE. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event. Debuggers can use EDPRSR.{SDR, HALTED} to determine the Execution state of the PE.

Note

Before generating a Restart request trigger event for a PE, a debugger must ensure any Debug request trigger event targeting that PE is cleared. *Debug request trigger event* on page H5-6797 describes how to do this.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. The trigger event is acknowledged even if the request is ignored by the PE. See also *Exiting Debug state* on page H2-6740.

H5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

Note

To reduce the latency of halting, Arm recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, that might be derived from the Cross-halt trigger event, to be recorded in the EDSCR.STATUS field. This applies to Debug request trigger events that are acting as inputs to the PE.

H5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE asserts a new Performance Monitors counter overflow interrupt request. See Chapter D7 *The Performance Monitors Extension*.

If the CTI supports multicycle trigger events, then the trigger event remains asserted until the overflow is cleared by a write to PMOVSCLR_EL0. Otherwise, the trigger event is asserted when the value of PMOVSCLR_EL0 changes from zero to a non-zero value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
- Events can be counted when `ExternalNoninvasiveDebugEnabled()`==FALSE, and, in Secure state, when `ExternalSecureNoninvasiveDebugEnabled()`==FALSE. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.

H5.4.5 Statistical Profiling Extension sample trigger event

If the Statistical Profiling Extension is implemented, and a sample record is written to memory, CTI input trigger 2 is asserted. This trigger might also be directly connected to other IMPLEMENTATION DEFINED debug features.

For more information see Chapter D9 *The Statistical Profiling Extension*.

H5.4.6 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL PE Trace Unit, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL PE Trace Unit.
- The OPTIONAL PE Trace Unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to remove the events.

H5.4.7 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL PE Trace Unit, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL PE Trace Unit.
- The OPTIONAL PE Trace Unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external output trigger events.

H5.4.8 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, PE Trace Units, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

Note

- Arm recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.
- GICv3 reserves a private peripheral interrupt number for this interrupt.

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[2]. This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

Arm recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.

H5.5 CTI registers programmers' model

The CTI registers programmers' model is described in Chapter H8 *About the External Debug Registers*. The following sections contain information specific to the CTI:

- *External debug register resets* on page H8-6847.
- *External debug interface register access permissions* on page H8-6835.
- *Cross-trigger interface registers* on page H8-6845.
- The individual register descriptions in *Cross-Trigger Interface registers* on page H9-6960.

See also *Memory-mapped accesses to the external debug interface* on page H8-6832.

H5.5.1 CTI reset

An External Debug reset resets the CTI. See *External debug register resets* on page H8-6847 for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

Note

An indirect read of an output trigger might not observe the deasserted state until the processor is Cold reset. For more information, see *Synchronization of changes to the external debug registers* on page H8-6828.

H5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- CTITRIGINSTATUS shows the status of the input triggers and CTICHINSTATUS shows the status of the input channels, regardless of the value of `ExternalNoninvasiveDebugEnabled()`.

  Note

  The PE does not generate the Cross-halt trigger event and the PE Trace Unit does not generate Generic trace external output trigger events when `ExternalNoninvasiveDebugEnabled()`==FALSE. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of `ExternalInvasiveDebugEnabled()`.

  Note

  The PE ignores Debug request and Restart request trigger events when `ExternalInvasiveDebugEnabled()`==FALSE. The PE Trace Unit ignores Generic trace external input trigger events when `ExternalNoninvasiveDebugEnabled()`==FALSE. The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when `ExternalInvasiveDebugEnabled()`==FALSE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

  Note

  This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. Arm recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the PE Trace Unit. They can do this:
  - To pass trace events between Trace Units.
  - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the PE Trace Unit.
  - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
  - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- *Halting a single PE*.
- *Halting all PEs in a group when any one PE halts* on page H5-6803.
- *Synchronously restarting a group of PEs* on page H5-6803.
- *Halting a single PE on Performance Monitors overflow* on page H5-6803.

Example H5-1 Halting a single PE

To halt a single PE, set:

1. CTIGATE[0] to 0, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. CTIOUTEN0[0] to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

   Note

   The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instance of CTIOUTEN<n> for which <n> is 0.

3. CTIAPPPULSE[0] to 1, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example H5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. CTIGATE[2] to 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. CTIINEN0[2] to 1, so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.
3. CTIOUTEN0[2] to 1, so that each CTI generates a Debug request trigger event in response to a channel event on channel 2.

   Note

   The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instances of CTIINEN<n> and CTIOUTEN<n> for which <n> is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1to CTIINTACK[0], before restarting the PE.

Example H5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group:

1. If the PE was halted because of a Debug request trigger event, the debugger must ensure the trigger event is deasserted. It can do this by:
   a. Writing 1 to CTIINTACK[0] to clear the Debug request trigger event.
   b. Polling CTITRIGOUTSTATUS[0], until it reads as 0, to confirm that the trigger event has been deasserted.
2. Set CTIGATE[1] to 1, so that each CTI passes channel events on internal channel 1 to the CTM.
3. Set CTIOUTEN1[1] to 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

   Note

   This example must use the instance of CTIOUTEN<n> for which <n> is 1.

4. Set CTIAPPPULSE[1] to 1 on any one PE in the group, to generate a channel event on channel 1.

Example H5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. CTIGATE[3] to 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. CTIINEN1[3] to 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

   Note

   This step of this example must use the instance of CTIINEN<n> for which <n> is 1.

3. CTIOUTEN0[3] to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This step of this example must use the instance of CTIOUTEN<n> for which <n> is 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE. Clear the overflow status by writing to PMOVSCLR_EL0.

Chapter H6
Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- *About Debug over powerdown* on page H6-6806.
- *Power domains and debug* on page H6-6807.
- *Core power domain power states* on page H6-6808.
- *Emulating low-power states* on page H6-6811.
- *Powerup request mechanism* on page H6-6810.
- *Debug OS Save and Restore sequences* on page H6-6813.
- *Reset and debug* on page H6-6819.

Note

Where necessary, Table K14-1 on page K14-7810 disambiguates the general register references used in this chapter.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.1 About Debug over powerdown

Armv8 external debug defines a logical model for the hardware on which a PE executes. This hardware is logically split into the *Core power domain* and the *Debug power domain*, and the model contains descriptions of the states of those domains. See:

- *Power domains and debug* on page H6-6807.
- *Core power domain power states* on page H6-6808.

An implementation may allow power domains to be powered up and down independently. Debug over powerdown provides:

- A facility for software executing on the PE to save and restore the PE state on behalf of a self-hosted or external debugger or both. See *Debug OS Save and Restore sequences* on page H6-6813.
- A facility for an external debugger to request power up of the Core power domain. See *Powerup request mechanism* on page H6-6810.
- A facility for an external debugger, or software executing on the PE, to request emulation of powerdown of the Core power domain. See *Emulating low-power states* on page H6-6811.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.2 Power domains and debug

Armv8 external debug has two logical power domains, each with its own reset:

- The Debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. Registers in this domain are reset by an External Debug reset.
- The Core power domain contains the rest of the PE, and might be allowed to power up and power down independently of the Debug power domain.

Note

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers' model.
- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers' model is a valid implementation.

The Core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

For information about which groups of registers and components are in each power domain, and which registers change power domain if ARMv8.3-DoPD is implemented, see:

- *Access permissions for the External debug interface registers* on page H8-6841.
- *Cross-trigger interface registers* on page H8-6845.
- *Management register access permissions* on page K2-7656.
- *Access permissions for external views of the Performance Monitors* on page I3-7027.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.3 Core power domain power states

The Arm architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. Armv8 external debug uses a four logical power states model for the Core power domain. The four logical power states are as follows:

Normal The Core power domain is fully powered up and the debug registers are accessible.

Standby The Core power domain is on, but there are measures to reduce energy consumption. In a typical implementation, the PE enters standby by executing a `WFI` or `WFE` instruction, and exits on a wake-up event. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby.

The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE.

Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the Debug architecture requires only the following:

- An External Debug Request debug event is a wake-up event when halting is allowed. This means that the PE must exit standby to handle the debug event. If the PE executed a `WFE` or a `WFI` instruction to enter standby, then it retires that instruction,
- If the external debug interface is accessed, the PE must respond to that access. Arm recommends that, if the PE executed a `WFI` or `WFE` instruction to enter standby, then it does not retire that instruction.

Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention The OS takes some measures, including IMPLEMENTATION DEFINED code sequences and registers, to reduce energy consumption. The PE state, including debug settings, is preserved in low-power structures, allowing the Core power domain to be at least partially turned off.

Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. If software has to use an IMPLEMENTATION DEFINED code sequence before entering, or after leaving, a retention state, this is referred to as a *software-visible retention state*. It is IMPLEMENTATION DEFINED whether the value of DBGPRCR.CORENPDRQ is set to the value of EDPRCR.COREPURQ on leaving the software-visible retention state.

External Debug Request debug events stay pending and registers in the Core power domain cannot be accessed.

Note

- This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.

Powerdown The OS takes some measures to reduce energy consumption by turning the Core power domain off. These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown.

If ARMv8.0-DoubleLock is implemented, it is used during powerdown.

Changing from powerdown to normal operation must include:

- A Cold reset of the PE after the power level has been restored.
- The OS restoring the saved PE state.

External Debug Request debug events stay pending and debug registers in the Core power domain cannot be accessed.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

An implementation might support enabling and disabling threads, either dynamically or once at reset time. Threads that are disabled in this way must appear to the external debugger as either:

- Powered off, meaning they are either:
  - In a powerdown state.
  - In a retention state.
- Held in reset state.

Armv8 external debug uses a simpler two states model for the Debug power domain. The two states are:

Off The Debug power domain is turned off.

On The Debug power domain is turned on.

The available power states, including the cross-product of Core power domain and Debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

Note

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the Debug power domain to be on when the Core power domain is off.

If the Debug power domain is implemented but not powered up when the Core power domain is powered up, the Reset Catch debug event and the OS Unlock Catch debug event are disabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.4 Powerup request mechanism

If a powerup request mechanism is implemented, asserting the powerup request requests the power controller to power up the Core power domain, and to emulate any subsequent powerdown requests, until the powerup request mechanism is deasserted.

DBGPRCR.CORENPDRQ is set to the value of the powerup request at reset.

H6.4.1 Powerup request mechanism if ARMv8.3-DoPD is implemented

If ARMv8.3-DoPD is implemented, the external debug component implements an OPTIONAL powerup request mechanism.

If the powerup request mechanism is implemented, the powerup request must be a CoreSight Class 0x9 ROM table block that contains both:

- A parent entry for the debug registers of the PE.
- A parent entry for the PMU registers of the PE, if the OPTIONAL PMU with an external debug interface is implemented.

A parent entry of a component is an entry in a ROM table that either locates the component, or locates another ROM table that contains the parent entry for the component.

Note

The ROM table and any descendants might describe other debug components, including debug components for other PEs.

The ROM table might have a parent entry in a second ROM table and that parent entry might also have a powerup request mechanism in the second ROM table. This applies recursively.

The parent entries for the debug components have the following properties:

For the debug registers and Performance Monitors registers:

These components are in the Core power domain.

The POWERIDVALID bit is 1.

All parent entries must have the same IMPLEMENTATION DEFINED POWERID value.

Note

The IMPLEMENTATION DEFINED POWERID value does not need to be unique for each PE.

For the CTI registers:

This component is in the Debug power domain.

The POWERIDVALID bit is IMPLEMENTATION DEFINED.

If the POWERIDVALID bit is 1, the entries must have a valid POWERID value.

For more information about Coresight Class 0x9 ROM Tables, see *ARM® CoreSight™ Architecture Specification*.

H6.4.2 Powerup request mechanism if ARMv8.3-DoPD is not implemented

If ARMv8.3-DoPD is not implemented, the bit EDPRCR.COREPURQ is the powerup request mechanism.

The control registers DBGPRCR.CORENPDRQ and EDPRCR.COREPURQ provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.5 Emulating low-power states

DBGPRCR.CORENPDRQ and the powerup request mechanism can request the power controller to emulate states where the Core power domain is completely off or in a low-power state where the Core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.

If ARMv8.3-DoPD is not implemented, EDPRSR.{SPD, PU} indicates the Core power domain power state. For more information see:

- The DBGPRCR_EL1 and DBGPRCR System register descriptions.
- The EDPRCR and EDPRSR external debug register descriptions.
- Appendix K2 *Recommended External Debug Interface*.

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug, PMU, CTI, and trace unit registers that are accessible on the external debug interface and are in one of:

- The Debug power domain.
- The Core power domain.
- When a trace unit with a separate trace unit Core power domain is implemented, and the trace unit Core power domain is powered on, the trace unit Core power domain.

That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence.

Arm recommends that any IMPLEMENTATION DEFINED registers that are on the external debug interface and in either the Core power domain or the Debug power domain are also accessible in an emulated powerdown state.

If ARMv8.0-DoubleLock is implemented, `DoubleLockStatus() == FALSE` when DBGPRCR.CORENPDRQ == 1.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

Example H6-1 and Example H6-2 are examples of two approaches to emulating powerdown.

Example H6-1 An example of emulating powerdown

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

Example H6-2 Another example of emulating powerdown

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset. As such, the effect of accessing any register that is reset by a Warm reset while the PE is in the emulated powerdown state will have an IMPLEMENTATION DEFINED effect on that register.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, RMR_ELx is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
- The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.
- Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.

H6.6 Debug OS Save and Restore sequences

In Armv8-A, the following registers provide the OS Save and Restore mechanism:

- The *OS Lock Access Register*, OSLAR, locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The *OS Lock Status Register*, OSLSR, shows the status of the OS Lock.
- The PE can be configured to generate an *OS Unlock Catch debug event* on page H3-6762 when the OS Lock is unlocked.
- If ARMv8.0-DoubleLock is implemented, the OS Double Lock locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:

- *ARMv8.0-DoubleLock* on page A2-64
- *Reset and debug* on page H6-6819
- Appendix K8 *Example OS Save and Restore Sequences*

H6.6.1 EDPRSR.{DLK, SPD, PU} and the Core power domain

If ARMv8.3-DoPD is not implemented, a debugger uses EDPRSR.{DLK, SPD, PU} to determine whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read.

Table H6-1 Interpretation of the EDPRSR.{DLK, SPD, PU} bits

EDPRSR			Core power domain			Notes
DLK	SPD	PU	Power	Accesses	State lost	
0	0	1	On	OK	No	-
0	1	1	On	OK	Yes	SPD is cleared to 0 following the read.
1	X	1	On	Error	Not known	ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE. Software locks the OS Double Lock before removing power.
X	1	0	Off	Error	Yes	A Cold reset will be asserted on exiting powerdown state, but not on exiting low-power retention state.
X	0	0	Not known	Error	Not known	

If ARMv8.3-DoPD is implemented, accesses to EDPRSR return an error when the Core power domain is off or in a retention state, meaning successful reads of EDPRSR always return 1 for EDPRSR.PU.

When ARMv8.4-Debug is implemented, and whenever ARMv8.0-DoubleLock is not implemented, EDPRSR.DLK is always 0.

If ARMv8.0-DoubleLock is not implemented, `DoubleLockStatus()` always returns FALSE.

If the Core power domain is powered up and `DoubleLockStatus()` == TRUE, then:

- When ARMv8.2-Debug is not implemented, EDPRSR.{DLK, SPD, PU} can read either {1, UNKNOWN, 1} or {UNKNOWN, 0, 0}.
- When ARMv8.2-Debug is implemented, and ARMv8.4-Debug is not implemented, EDPRSR.{DLK, SPD, PU} can only read {UNKNOWN, 0, 0}.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.6.2 EDPRSR.SPD when the Core domain is in either retention or powerdown state

If ARMv8.3-DoPD is not implemented, when the Core power domain is in either the retention or powerdown state, EDPRSR.SPD is not cleared following a read of EDPRSR and it is IMPLEMENTATION DEFINED whether:

- EDPRSR.SPD shows whether the state of the debug registers in the Core power domain has been lost since the last time that EDPRSR was read. This means that:
  - When the Core power domain is in the powerdown state, EDPRSR.SPD is RAO, this indicates that the state of the debug registers has been lost.
  - When the Core power domain is in the retention state, EDPRSR.SPD indicates whether the state of the debug registers was lost before the Core power domain entered retention state.
- EDPRSR.SPD is RAZ, and:
  - On leaving the powerdown state, EDPRSR.SPD is set to 1 which indicates that the state of the debug registers has been lost.
  - On leaving the retention state, EDPRSR.SPD reverts the value it had on entering the retention state.

Note

If ARMv8.3-DoPD is implemented, accesses to EDPRSR return an error when the Core power domain is off or in a retention state.

H6.6.3 EDPRSR.{DLK, R} and reset state

If ARMv8.3-DoPD is implemented, accesses to EDPRSR return an error when the Core power domain is off or in a retention state, meaning successful reads of EDPRSR always return 1 for EDPRSR.PU.

When ARMv8.4-Debug is implemented, and whenever ARMv8.0-DoubleLock is not implemented, EDPRSR.DLK is always 0.

If ARMv8.0-DoubleLock is not implemented, `DoubleLockStatus()` always returns FALSE.

If ARMv8.0-DoubleLock is implemented and enabled, the behavior of all registers and fields except EDPRSR.DLK is the same as their behavior if ARMv8.4-Debug is not implemented.

If ARMv8.4-Debug is implemented EDPRSR.DLK is always 0 and does not give any information about the OS Double Lock.

EDPRSR.R is UNKNOWN when `DoubleLockStatus()` == TRUE. OSDLR_EL1.DLK is cleared to 0 by a reset. If the Core power domain is powered up and entered reset state with the OS Double Lock locked, it is CONSTRAINED UNPREDICTABLE whether a read of EDPRSR while the PE is in reset state returns:

- EDPRSR.{DLK, R, PU} == {1, UNKNOWN, 1} indicating that the OS Double Lock is locked. This is not permitted from Armv8.2.
- EDPRSR.{DLK, R, PU} == {0, 1, 1} indicating that the PE is in reset state.
- EDPRSR.{DLK, R, PU} == {UNKNOWN, UNKNOWN, 0} indicating that the registers in the Core power domain cannot be accessed because the OS Double Lock is locked.

If the PE was powered up and the OS Double Lock was unlocked when the PE was reset, then EDPRSR.{DLK, R, PU} reads as {0, 1, 1} while the PE is in reset state.

On leaving reset state, EDPRSR.{DLK, R} reads as {0, 0}.

H6.6.4 Debug registers to save over powerdown

Table H6-2 shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
  - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when OSLSR.OSLK is locked. These registers include OSECCR, OSDTRRX, and OSDTRTX.
- Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. DBGVCR32_EL2 and SDER32_EL3 are only required to support AArch32.

Table H6-2 does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

Table H6-2 Debug registers to save over powerdown

Register in AArch64 state	Register in AArch32 state	Self-hosted	External
MDSCR_EL1	DBGDSCRext	Yes	Yes[a]
DBGBVR<n>_EL1	DBGBVR<n>	Yes	Yes
DBGBCR<n>_EL1	DBGBCR<n>	Yes	Yes
DBGWVR<n>_EL1	DBGWVR<n>	Yes	Yes
DBGWCR<n>_EL1	DBGWCR<n>	Yes	Yes
DBGVCR32_EL2	DBGVCR	Yes	-
MDCR_EL2	HDCR	Yes	-
SDER32_EL3	SDER	Yes	-
MDCR_EL3	SDCR	Yes[b]	-
MDCCINT_EL1	DBGDCCINT	-	Yes[b]
DBGCLAIMSET_EL1 DBGCLAIMCLR_EL1	DBGCLAIMSET, DBGCLAIMCLR	-	Yes[c]
OSECCR_EL1	DBGOSECCR	-	Yes[ab]
OSDTRRX_EL1 OSDTRTX_EL1	DBGDTRRXext DBGDTRTXext	-	Yes

a. The OS Lock must be locked to save and restore for external debug. When the OS Lock is locked, DSCR is part of the software save and restore mechanism for external debug. It provides a mechanism for an operating system to access some fields of EDSCR that are otherwise read-only or not visible to software. This allows the operating system to save and restore these settings over a powerdown for the external debugger.

b. This register is new in Armv8-A. Sequences written for Armv7 do not preserve the register over powerdown.

c. Read DBGCLAIMCLR to save, write DBGCLAIMSET to restore.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.6.5 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by:
   - Writing the key value `0xC5ACCE55` to the DBGOSLAR in AArch32 state.
   - Writing 1 to OSLAR_EL1.OSLK in AArch64 state.
2. Execute an `ISB` instruction.
3. Walk through the debug registers listed in *Debug registers to save over powerdown* on page H6-6815 and save the values to the nonvolatile storage.

If the ARMv8.0-DoubleLock is implemented, before removing power from the Core power domain, software must:

1. Lock the OS Double Lock by:
   - Writing 1 to DBGOSDLR.DLK in AArch32 state.
   - Writing 1 to OSDLR_EL1.DLK in AArch64 state.

   If ARMv8.0-DoubleLock is not implemented, OSDLR_EL1 and DBGOSDLR ignore writes.
2. Execute a *Context synchronization event*.

H6.6.6 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

1. Lock the OS Lock, as described in *OS Save sequence*. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an `ISB` instruction.
3. To ensure that, if an external debugger clears the OS Lock before the end of this sequence, no debug exceptions are generated:
   - Write 0 to MDSCR_EL1 if executing in AArch64 state.
   - Write 0 to DBGDSCRext if executing in AArch32 state.
4. Walk through the debug registers listed in *Debug registers to save over powerdown* on page H6-6815, and restore the values from the nonvolatile storage. The last register to be restored must be:
   - MDSCR_EL1 if executing in AArch64 state.
   - DBGDSCRext if executing in AArch32 state.
5. Execute an `ISB` instruction.
6. Unlock the OS Lock by:
   - Writing any non-key value to DBGOSLAR if executing in AArch32 state.
   - Writing 0 to OSLAR_EL1.OSLK if executing in AArch64 state.
7. Execute a *Context synchronization event*.

Note

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

H6.6.7 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the OS Lock is locked:

- Access to debug registers through the System register interface is mainly unchanged except that:
  - Certain registers are read and written without side-effects.
  - Fields in DSCR and OSECCR that are normally read-only become read/write.

  This allows the state to be saved or restored. For more information, see the relevant register description in Chapter H9 *External Debug Register Descriptions*.
- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information see *External debug interface register access permissions summary* on page H8-6837.
- Debug exceptions, other than Breakpoint Instruction exceptions are not generated.
- Breakpoint and Watchpoint debug events are not generated. The OS Lock has no effect on Breakpoint Instruction exceptions and other debug events.

H6.6.8 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, the PE sets EDESR.OSUC to 1 if the OS Unlock Catch debug event is enabled and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. See *OS Unlock Catch debug event* on page H3-6762.

H6.6.9 Debug behavior when the OS Double Lock is locked

If the ARMv8.0-DoubleLock is implemented, software locks the OS Double Lock immediately before a powerdown sequence.

The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When `DoubleLockStatus()` == TRUE:

- The external debug interface only has restricted access to the debug registers, so that it is quiescent before removing power. See *External debug interface register access permissions summary* on page H8-6837.
- Debug exceptions, other than Breakpoint Instruction exceptions, are not generated.
- Halting is prohibited. See *Halting allowed and halting prohibited* on page H2-6705.

  Note

  Pending Halting debug events might be lost when core power is removed.

- No asynchronous debug events are `WFI` or `WFE` wake-up events.

If the ARMv8.0-DoubleLock is not implemented, the PE ensures these conditions are met before allowing power to be removed.

Software must synchronize the update to OSDLR before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the OSDLR update before issuing the `WFI` instruction.

OSDLR.DLK is ignored and `DoubleLockStatus()` == FALSE if either:

- The PE is in Debug state.
- DBGPRCR.CORENPDRQ is set to 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

It is possible to enter Debug state with OSDLR.DLK set to 1. This is because a *Context synchronization event* is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the OSDLR update is synchronized.

Because OSDLR.DLK is ignored when DBGPRCR.CORENPDRQ is set to 1, an external debugger can write to DBGPRCR.CORENPDRQ, and the ARMv8.0-DoubleLock is not always implemented, software must not rely on using the OS Double Lock to disable debug exceptions or to prohibit halting, or both. Arm deprecates use of the OS Double Lock for these purposes, and instead recommends that software:

- Uses the OS Lock to disable debug exceptions during save or restore sequences.
- Uses the debug authentication interface to prohibit halting and external debug access to debug registers at times other than immediately prior to removing power.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, if the ARMv8.0-DoubleLock is implemented, it is important to avoid race conditions that defeat this purpose. Arm recommends that:

- Once the write to OSDLR.DLK has been synchronized by a *Context synchronization event* and `DoubleLockStatus()` == TRUE, a PE must:
  - Not allow a debug event generated before the *Context synchronization event* to cause an entry to Debug state or act as a wake-up event for a `WFI` or `WFE` instruction after the *Context synchronization event* has completed.
  - Complete any external debug access started before the *Context synchronization event* by the time the *Context synchronization event* completes.

    Note

    A debug register access might be in progress when software sets OSDLR.DLK to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets OSDLR.DLK to 1 must complete or return an error in finite time.

- If a write to DBGPRCR or EDPRCR made when OSDLR.DLK == 1 changes DBGPRCR.CORENPDRQ or EDPRCR.CORENPDRQ from 1 to 0, meaning `DoubleLockStatus()` changes from FALSE to TRUE, then before signaling to the system that the CORENPDRQ field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus()` == TRUE listed in this section are met.

In a standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to CORENPDRQ are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus()` == FALSE, an external debugger can clear the OS Lock at any time, and then write to EDPRCR.

H6.7 Reset and debug

All registers in the Core power domain are either:

- Reset by both a Cold and a Warm reset.
- Reset only by a Cold reset and are not changed by a Warm reset.

For more information, see *Reset* on page D1-2289.

All registers in the Debug power domain are reset by an External Debug reset.

Figure H6-1 shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

As shown in the figure, the external debug logic is split between the Debug power domain and the Core power domain.

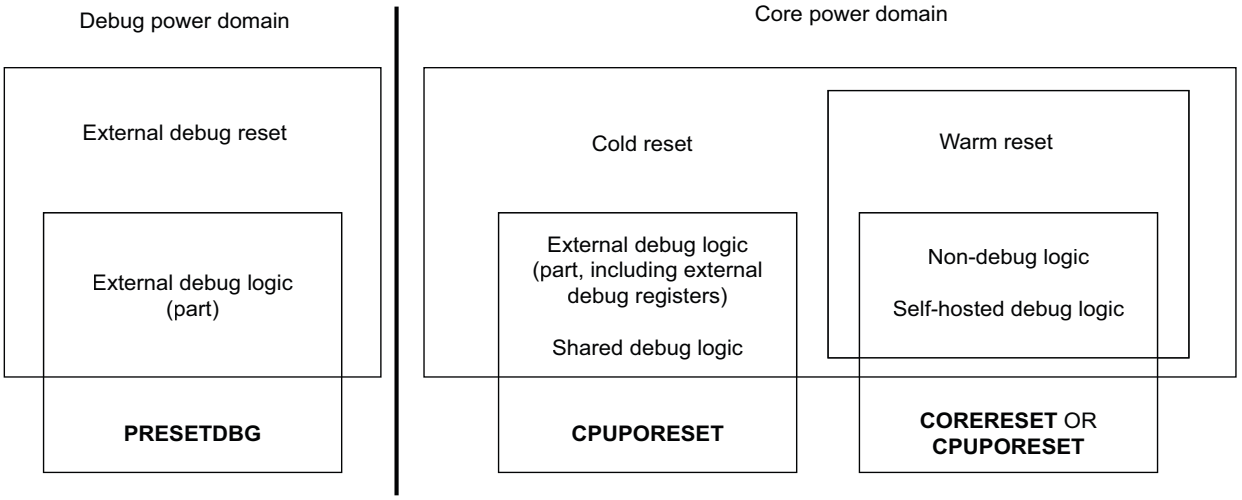

Figure H6-1 Power and reset domains

For more information about power domains and power states, see *Power domains and debug* on page H6-6807.

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

Note

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

CPUPORESET is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also *Emulating low-power states* on page H6-6811 and the EDPRSR register description.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H6.7.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
  - Then, if the register or register field is reset by that reset signal, it is CONSTRAINED UNPREDICTABLE whether the register or register field takes the reset value or the value written. The reset value might be UNKNOWN.
  - Otherwise the register or register field takes the value that is written.
- Reads a register, or indirectly reads a register or register field, as part of an access:
  - Then, if the register or register field is reset by that reset signal, the value returned in UNKNOWN.
  - Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.

Chapter H7
The PC Sample-based Profiling Extension

This chapter describes the OPTIONAL PC Sample-based Profiling Extension that provides a non-invasive external debug component.

It contains the following section:

- *About the PC Sample-based Profiling Extension* on page H7-6822.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H7.1 About the PC Sample-based Profiling Extension

The PC Sample-based Profiling Extension is an OPTIONAL extension that provides coarse-grained, non-invasive profiling by an external debugger. See also *Non-invasive behavior* on page D7-2673.

PC Sample-based Profiling creates samples so that tools can populate a statistical model of the performance of software executing on the PE.

Note

Data returned by periodic sampling of PC Sample-based Profiling registers is sufficient to allow tools to estimate the distribution of time spent executing software on the PE.

The delay between an instruction being executed by the PE and its address appearing in the PC Sample Register is not defined, and Armv8 does not require that the sampled instruction was recently executed. For example, if a piece of software executes a load instruction that reads the PC Sample Register of the PE it is running on, there is no guaranteed relationship between the address of the load instruction and the value read. The PC Sample Register is intended only for use by an external agent to provide statistical information for software profiling.

It must be possible to sample references to branch targets. It is IMPLEMENTATION DEFINED whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the sampled data is acceptable. Arm does not define *a reasonable degree of inaccuracy* but recommends the following guidelines:

- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the sample to represent an instruction that was not committed for execution.
- Under unusual non-repeating pathological cases, the sample can represent an instruction that was not committed for execution. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in sampling is very unlikely.
- Under normal operating conditions, the sample must reference an instruction that was committed for execution, including its context, and must not reference instructions that are fetched but not committed for execution.

Note

In the Armv7 PC Sample-based Profiling Extension, an offset was applied to the sampled program counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. In the Armv8 PC Sample-based Profiling Extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

- *Controlling the PC Sample-based Profiling Extension*.
- *Registers implemented by the PC Sample-based Profiling Extension* on page H7-6823.
- *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824.
- *Pseudocode description of PC Sample-based Profiling* on page H7-6824.

H7.1.1 Controlling the PC Sample-based Profiling Extension

PC Sample-based Profiling is controlled by the IMPLEMENTATION DEFINED authentication interface `ExternalNoninvasiveDebugEnabled()`.

PC Sample-based Profiling is prohibited unless both:

- It is allowed by the IMPLEMENTATION DEFINED authentication interface `ExternalNoninvasiveDebugEnabled()`.
- At least one of the following applies:
  - The PE is executing in Non-secure state.
  - EL3 is not implemented.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— EL3 is implemented, the PE is executing in Secure state, and non-invasive debug is allowed by the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().

— EL3 is implemented, EL3 or EL1 is using AArch32, the PE is executing at EL0 in Secure state, and the value of SDER.SUNIDEN is 1.

The state of the IMPLEMENTATION DEFINED authentication interface is visible through DBGAUTHSTATUS_EL1. See *Recommended authentication interface* on page K2-7653.

H7.1.2 Registers implemented by the PC Sample-based Profiling Extension

The options for implementing the PC Sample-based Profiling extension are:

- The extension is implemented in the external debug register space. EDDEVID.PCSample and identifies the implemented level of profiling, and EDDEVID1.PCSROffset also indicates that this option is implemented.

  From Armv8.2 this option is not permitted.

- ARMv8.2-PCSample is implemented, meaning the PC Sample-based Profiling extension is implemented in the Performance Monitors memory-mapped register space. PMDEVID.PCSample identifies the implemented level of profiling.

If PC Sample-based Profiling is implemented in the external debug register space:

- The following external debug registers can be implemented:
  — EDCIDSR.
  — EDPCSR.
  — EDVIDSR.

  See *External debug interface register map* on page H8-6839.
- If ARMv8.1-VHE is implemented, EDSCR.SC2 controls what PC Sample-based Profiling samples.

If ARMv8.2-PCSample is implemented, the following registers can be implemented in the Performance Monitors memory-mapped register space:

- PMCID1SR and PMCID2SR.
- PMPCSR.
- PMVIDSR.

See *Performance Monitors external register views* on page I5-7036.

If the PC Sample-based Profiling Extension is implemented with ARMv8.2-PCSample but the Performance Monitors Extension is not implemented, then the PC Sample-based Profiling Extension is implemented in its own memory-mapped register space, within the area that is reserved for the Performance Monitors, see Table H7-1. If CoreSight compliance is required:

- The management registers are defined as in Table K2-3 on page K2-7655.
- The support for PC Sample-based profiling is defined in the following registers:
  — PMDEVTYPE.MAJOR has the value 0x0.
  — PMDEVARCH.ARCHID has the value 0x0A10.

Table H7-1 PC Sample-based Profiling register map without the Performance Monitors Extension

Offset	Description
0x200	PMPCSR[31:0]
0x204	PMPCSR[63:32]
0x208	PMCID1SR
0x20C	PMVIDSR
0x220	PMPCSR[31:0] (alias)
0x224	PMPCSR[63:32] (alias)

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table H7-1 PC Sample-based Profiling register map without the Performance Monitors Extension

Offset	Description
0x228	PMCID1SR (alias)
0x22C	PMCID2SR
0x600-0x6FC	IMPLEMENTATION DEFINED
0xE80-0xEFC	IMPLEMENTATION DEFINED for CoreSight compliance
0xFF0-0xFFc	Management and CoreSight compliance registers

H7.1.3 Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN

The architecture permits IMPLEMENTATION DEFINED extensions to external debug to define mechanisms that make the values of the PC Sample-based profiling registers UNKNOWN. However, it requires that any such mechanism is disabled by default. This means that powerup or a hard reset of the PE must leave the PE in a state where the PC Sample-based Profiling Extension, if implemented, exhibits its architecturally-defined behavior.

Note

A mechanism that, when enabled, makes the PC Sample-based profiling registers UNKNOWN might use other sample-based profiling events that are appropriate for a use that is independent of PC Sample-based Profiling.

When EDPCSR or PMPCSR are read by the PE for the first time after exiting Debug state or Reset state, PMPCSR or EDPCSR will return the value 0xFFFFFFFF. Any subsequent read of PMPCSR or EDPCSR will return sampled instruction address values.

H7.1.4 Pseudocode description of PC Sample-based Profiling

When PC Sample-based Profiling is implemented but not with ARMv8.2-PCSample, the functionality is described by the pseudocode functions:

- `CreatePCSample()`, which populates a variable of type `PCSample`.
- `EDPCSRlo[]`, which writes a PC sample to the EDPCSR and associated registers.

When ARMv8.2-PCSample is implemented, the functionality is described by the pseudocode functions:

- `CreatePCSample()`, which populates a variable of type `PCSample`.
- `PMPCSR[]`, which writes a PC Sample to the PMPCSR and associated registers.

Chapter H8
About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

- *Relationship between external debug and System registers* on page H8-6826.
- *Endianness and supported access sizes* on page H8-6827.
- *Synchronization of changes to the external debug registers* on page H8-6828.
- *Memory-mapped accesses to the external debug interface* on page H8-6832.
- *External debug interface register access permissions* on page H8-6835.
- *External debug interface registers* on page H8-6839.
- *Cross-trigger interface registers* on page H8-6845.
- *External debug register resets* on page H8-6847.

Note

H8.1 Relationship between external debug and System registers

Table H8-1 shows the relationship between external debug registers and System registers. Where no relationship exists, the registers are not listed.

Table H8-1 Equivalence between external debug and System registers

	System register		
External debug register	**AArch64**	**AArch32**	**Notes**
DBGDTRRX_EL0	DBGDTRRX_EL0	DBGDTRRXint	See also *Summary of System register accesses to the DCC* on page H4-6780
DBGDTRTX_EL0	DBGDTRTX_EL0	DBGDTRTXint	
OSLAR_EL1	OSLAR_EL1	DBGOSLAR	-
DBGBVR<n>_EL1[31:0] DBGBVR<n>_EL1[63:32]	DBGBVR<n>_EL1[31:0] DBGBVR<n>_EL1[63:32]	DBGBVR<n> DBGBXVR<n>	-
DBGBCR<n>_EL1	DBGBCR<n>_EL1	DBGBCR<n>	-
DBGWVR<n>_EL1[31:0] DBGWVR<n>_EL1[63:32]	DBGWVR<n>_EL1[31:0] DBGWVR<n>_EL1[63:32]	DBGWVR<n>	-
DBGWCR<n>_EL1	DBGWCR<n>_EL1	DBGWCR<n>	-
DBGCLAIMSET_EL1	DBGCLAIMSET_EL1	DBGCLAIMSET	-
DBGCLAIMCLR_EL1	DBGCLAIMCLR_EL1	DBGCLAIMCLR	-
DBGAUTHSTATUS_EL1	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS	Read-only
EDSCR	MDSCR_EL1	DBGDSCRext	Only some fields map
EDECCR	OSECCR_EL1	DBGOSECCR	Applies when the OS Lock is locked.
MIDR_EL1	MIDR_EL1	MIDR	Read-only copies of Processor ID Registers
EDDEVAFF0 EDDEVAFF1	MPIDR_EL1[31:0][a] MPIDR_EL1[63:32][a]	MPIDR	Read-only copies of system ID registers

a. This is a word of a 64-bit register.

In addition:

- EDSCR.{TXfull, RXfull} are read-only aliases for DCCSR.{TXfull, RXfull}.
- EDPRCR.CORENPDRQ is a read/write alias for DBGPRCR.CORENPDRQ.
- EDPRSR.OSLK is a read-only alias for OSLSR.OSLK.
- If the ARMv8.0-DoubleLock is implemented, EDPRSR.DLK is a read-only function of OSDLR.DLK.

H8.2 Endianness and supported access sizes

The debug registers, Performance Monitors registers, and CTI registers are implemented as memory-mapped peripherals. The Arm architecture requires memory-mapped peripherals to be little-endian.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitors registers, and CTI registers, implementations must:

- Comply with the requirements of *Supported access sizes* on page I1-7008.
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations, even if no PE in the system implements AArch32.

Note

These requirements mean that a system implementing the debug registers using a 32-bit bus, such as a AMBA APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIv5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

H8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- *Synchronization and debug exceptions* on page D2-2459 for exceptions taken from AArch64 state.
- *Synchronization and debug exceptions* on page G2-5674 for exceptions taken from AArch32 state.
- *Synchronization and Halting debug events* on page H3-6765.
- *Synchronization of DCC and ITR accesses* on page H4-6780.

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads, and indirect writes.

Note

Synchronization requirements for AArch64 System registers on page D13-2819 and *Synchronization of changes to AArch32 System registers* on page G8-5896 define direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

For general information about synchronization, access completion, ordering, and observability, see *Synchronization of memory-mapped registers* on page I1-7010.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, and DBGWVR<n>_EL1, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Synchronization of DCC and ITR accesses on page H4-6780 describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the master of the authentication interface. See *Synchronization and the authentication interface* on page H8-6829.

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a `DSB` barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

Note

For an external Debug Access Port, access completion is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an `ISB` instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an `ISB` instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to EDITR.

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, DBGBCR<n>_EL1 and DBGBVR<n>_EL1.
- The watchpoint registers, DBGWCR<n>_EL1 and DBGWVR<n>_EL1.

This guarantee only applies to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example EDSCR, or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in *Examples of the synchronization of changes to the external debug registers*.

Some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means that simultaneous writes must be merged. Registers that have this property and support both external debug and System register access include DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, PMCR_EL0.{C,P}, PMOVSSET_EL0, PMOVSCLR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, and PMSWINC_EL0. This last register is OPTIONAL and deprecated in the external debug interface.

H8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the state of the PE by the master of the authentication interface.

For an external debug interface read of any Authentication Status register, or an indirect read of the authentication interface made in determining the response to a subsequent external debug interface access, a change on the authentication interface must be observable following a subsequent explicit *Context synchronization event*, and:

- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable in finite time.
- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable following an entry to Debug state.

For a System register read of DBGAUTHSTATUS_EL1, a change on the authentication interface is guaranteed to be observable only after a *Context synchronization event*.

Note

- In some systems the authentication interface is fixed by configuration, or changed under the control of software. These systems can require explicit synchronization for any change to the authentication interface.
- In other systems, the authentication interface is controlled dynamically by an external agent. In these systems, it is desirable that changes to the authentication interface do not require explicit synchronization by software executing on the PE to be observable by subsequent external debug interface accesses, and are either observable in finite time or are synchronized by entry to Debug state. Otherwise there are scenarios where a debugger is not able to halt and debug the system.

H8.3.2 Examples of the synchronization of changes to the external debug registers

Example H8-1, Example H8-2 on page H8-6830, and Example H8-3 on page H8-6830 show the synchronization of changes to the external debug registers.

Example H8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially DBGBVR<n>_EL1 is `0x8000` and DBGBCR<n>_EL1 is `0x0181`. This means that a breakpoint is enabled on the halfword T32 instruction at address `0x8000`.

A sequence of external writes occurs in the following order:

1. `0x0000` is written to DBGBCR<n>_EL1, disabling the breakpoint.
2. `0x9000` is written to DBGBVR<n>_EL1[31:0].

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

3. `0x0061` is written to DBGBCR<n>_EL1, enabling a breakpoint on the halfword at address `0x9002`.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address `0x8002` and `0x9000`.

Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
- If any of the DBGBCR<n>_EL1 or DBGWCR<n>_EL1 fields are modified at the same time as updating the address.

Example H8-2 Simultaneous accesses to DTR registers

Initially EDSCR.{TXfull, TXU, ERR} are 0. Then:

- `0x0DCCDA7A` is directly written to DBGDTRTX_EL0 by an `MSR` instruction.
- DBGDTRTX_EL0 is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of `0x0DCCDA7A` to DBGDTRTX_EL0 is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 clears EDSCR.TXfull to 0.
- EDSCR.{TXU, ERR} are unchanged.
- The external debug interface read returns `0x0DCCDA7A`.

If the indirect read of DBGDTRTX_EL0 by the external debug interface is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 causes an underrun and as a result EDSCR.{TXU, ERR} are both set to 1.
- The external debug interface returns an UNKNOWN value.
- Writing `0x0DCCDA7A` to DBGDTRTX_EL0 sets DTRTX to `0x0DCCDA7A` and EDSCR.TXfull to 1.

Example H8-3 Simultaneous writes to CLAIM registers

Initially all CLAIM tag bits are 0. Then:

- `0x01` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit *Context synchronization event*.
- `0x02` is written to DBGCLAIMSET_EL1 by an external write.

These events might happen at the same time and in either order.

After this:

- DBGCLAIMCLR_EL1 is read by a direct read.
- DBGCLAIMCLR_EL1 is read by an external read.

In this case, a direct read can return either `0x01` or `0x03`, and the external read can return either `0x02` or `0x03`.

The only permitted final result for the CLAIM tags is the value `0x03`, because this would be the result regardless of whether `0x01` or `0x02` is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See *Synchronization requirements for AArch64 System registers* on page D13-2819.

It is not possible for a direct read to return `0x01` and the external read to return `0x02`, because the writes to DBGCLAIMCLR_EL1 are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value `0x03`, and then, at the same time, two writes occur:

- `0x04` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit *Context synchronization event*.
- `0x01` is written to DBGCLAIMCLR_EL1 by an external write.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In this case only permitted final result for the CLAIM tags is the value `0x06`.

H8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is OPTIONAL. When memory-mapped access to the external debug interface is supported, the external debug interface is accessed as a little-endian memory-mapped peripheral.

If the external debug interface is CoreSight compliant, then an OPTIONAL Software Lock can be implemented for memory-mapped accesses to each component.

The Software Lock is OPTIONAL and deprecated. If ARMv8.4-Debug is implemented, the Software Lock is not implemented. If it is not implemented, the behavior is as if it is unlocked. The Software Locks are controlled by EDLSR and EDLAR, PMLSR and PMLAR, and CTILSR and CTILAR. See *Management registers and CoreSight compliance* on page K2-7655.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

Note

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in Armv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when OSLSR.OSLK == 1, meaning that the OS Lock is locked.

The following sections give more information about these memory-mapped accesses:

- *Register access permissions for memory-mapped accesses*.
- *Synchronization of memory-mapped accesses to external debug registers* on page H8-6833.

See also *Supported access sizes* on page I1-7008.

H8.4.1 Register access permissions for memory-mapped accesses

It is IMPLEMENTATION DEFINED whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU.

If ARMv8.4-Debug is implemented, the Secure view of a debug component is mapped into Secure physical memory and the Non-secure view is mapped into Non-secure physical memory.

If ARMv8.4-Debug is implemented, the access permissions are different in each Security state, but Secure and Non-secure views of the debug components are identical. Arm recommends the views are located at the same address in the Secure and Non-secure physical address maps.

If memory-mapped accesses are made through an ADIv5 interface, the Debug Access Port can block the access using **DBGSWENABLE**. This is outside the scope of the Armv8-A architecture. See *Arm® Debug Interface Architecture Specification ADIv5.0 to ADIv5.2*.

Effect of the OPTIONAL Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the OPTIONAL Software Lock is implemented, and EDLSR.SLK, PMLSR.SLK, or CTILSR.SLK is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
  - Read/write (RW) registers become read-only, writes ignored (RO/WI).
  - Write-only (WO) registers become writes ignored (WI).
- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Writes to EDLAR, PMLAR, and CTILAR are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if EDLSR.SLK is set to 1:

- EDSCR.{TXfull, TXU, ERR} are unchanged by a memory-mapped read from DBGDTRTX_EL0.
- EDSCR.{RXfull, RXO, ERR} are unchanged by a memory-mapped write to DBGDTRRX_EL0 that is ignored.
- EDSCR.{ITE, ITO, ERR} are unchanged by a memory-mapped write to EDITR that is ignored.
- OSLSR.OSLK is unchanged by a memory-mapped write to OSLAR_EL1 that is ignored.
- EDPCSR[63:32], EDCIDSR, and EDVIDSR are unchanged by a memory-mapped read from EDPCSR[31:0].

  Note

  Updating EDVIDSR, EDCIDSR, and EDPCSRhi are side-effects of reading EDPCSRlo, such that these registers contain the matching context for EDPCSRlo. The process that updates EDPCSRlo with PC samples is not a side-effect of the access. Reads of EDPCSRlo made when the Software Lock is locked can be used to profile software.

- PMPCSR[63:32], PMCID1SR/PMCID2SR, and PMVIDSR are unchanged by a memory-mapped read from PMPCSR[31:0].

  Note

  Updating PMVIDSR, PMCID1SR/PMCID2SR, and PMPCSR[31:0] are side-effects of reading PMPCSR[63:32], such that these registers contain the matching context for PMPCSR[63:32]. The process that updates PMPCSR[63:32] with PC samples is not a side-effect of the access. Reads of PMPCSR[63:32] made when the Software Lock is locked can be used to profile software.

- EDPRSR.{SDR, SPMAD, SDAD, SR, SPD} are unchanged by a memory-mapped read from EDPRSR.
- EDPRSR.SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
- The CLAIM tags are unchanged by memory-mapped writes to DBGCLAIMSET_EL1 and DBGCLAIMCLR_EL1 which are ignored.

Similarly, if PMLSR.SLK is set to 1, then EDPRSR.SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

Behavior of a not permitted memory-mapped access

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

Arm recommends that the error is returned as either:

- A synchronous external Data Abort.
- An SError interrupt.

H8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in *Synchronization of changes to the external debug registers* on page H8-6828 and *Synchronization of memory-mapped registers* on page I1-7010.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H8.5 External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered down or is in low-power state where the registers cannot be accessed.
- OSLSR.OSLK == 1. The OS Lock is locked.
- ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.
- The access is disabled by either the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For details, see *External debug interface register access permissions summary* on page H8-6837.

H8.5.1 External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- OSLSR.OSLK == 1, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.
- ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE. This means that the OS Double Lock is locked. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

If ARMv8.0-DoubleLock is not implemented, the hardware must provide another method to safely remove Core power.

The OS Lock condition does not apply to the following debug registers:

- OSLAR_EL1. This means that an external debugger can override this lock.
- EDESR. This means that an external debugger can program a debug event for when software unlocks the OS Lock. See *OS Unlock Catch debug event* on page H3-6762.
- The ID registers that describe the PE to the debugger.

See also *Debug registers to save over powerdown* on page H6-6815.

H8.5.2 External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled. If EL3 is implemented, then SDCR provides additional external access controls for those registers.

The disable applies to:

- The DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, and DBGWCR<n>_EL1 registers.
- From Armv8.2, the OSLAR_EL1 register.

If ARMv8.2-Debug is not implemented, it is IMPLEMENTATION DEFINED whether the disable applies to OSLAR_EL1.

If ARMv8.4-Debug is not implemented, the external debug interface cannot access these registers if any of the following are true:

- `ExternalInvasiveDebugEnabled()` == FALSE.
- `ExternalSecureInvasiveDebugEnabled()` == FALSE, EL3 is not implemented, and the PE behaves as if the Security state is Secure.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- `ExternalSecureInvasiveDebugEnabled()` == FALSE, EL3 is implemented and SDCR.EDAD == 1.

If ARMv8.4-Debug is implemented, Non-secure accesses from the external debug interface to these registers are not permitted if any of the following are true:

- EL3 is not implemented and the PE behaves as if the Security state is Secure.
- EL3 is implemented and SDCR.EDAD == 1.

The `AllowExternalDebugAccess()` pseudocode function describes these accessibility rules.

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and SDCR provide similar external access disable controls for those registers.

If ARMv8.4-Debug is not implemented, the external debug interface cannot access the Performance Monitor registers if any of the following are true:

- `ExternalNoninvasiveDebugEnabled()` == FALSE.
- `ExternalSecureNoninvasiveDebugEnabled()` == FALSE, EL3 is not implemented and the PE behaves as if the Security state is Secure.
- `ExternalSecureNoninvasiveDebugEnabled()` == FALSE, EL3 is implemented and SDCR.EPMAD == 1.

If ARMv8.4-Debug is implemented, Non-secure accesses from the external debug interface to these registers are not permitted if any of the following are true:

- EL3 is not implemented and the PE behaves as if the Security state is Secure.
- EL3 is implemented and SDCR.EDAD == 1.

The `AllowExternalPMUAccess()` pseudocode function describes these accessibility rules.

Note

- Arm recommends that secure software that is not making use of debug hardware does not lock out the external debug interface.
- Armv8-A does not provide the equivalent control over access to Trace extension registers, which means if ARMv8.4-Debug is implemented, the Non-secure and Secure views are identical.

H8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIv5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in EDPRSR is indirectly written to 1 as a side-effect of the access:

- For a debug register access when `AllowExternalDebugAccess()` == FALSE, EDPRSR.SDAD is indirectly written to 1.
- For Performance Monitor register access when `AllowExternalPMUAccesss()` == FALSE, EDPRSR.SPMAD is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see *Register access permissions for memory-mapped accesses* on page H8-6832.

If no error is returned, or the error is returned because of a higher priority error condition, the flag in EDPRSR is unchanged.

See also *Behavior of a not permitted memory-mapped access* on page H8-6833.

For more information, see *Arm® Debug Interface Architecture Specification*.

H8.5.4 External debug interface register access permissions summary

For accesses to:

- IMPLEMENTATION DEFINED registers, see *IMPLEMENTATION DEFINED registers*.
- OPTIONAL registers for CoreSight compliance, see *Management registers and CoreSight compliance* on page K2-7655.
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see *Reserved and unallocated registers*.

For all other external debug interface, CTI, and Performance Monitor registers, Table H8-3 on page H8-6842,Table H8-4 on page H8-6843, Table H8-5 on page H8-6845 and Table I3-1 on page I3-7028, show the response of the PE to accesses by the external debug interface.

H8.5.5 IMPLEMENTATION DEFINED registers

For debug registers, Performance Monitors registers, CTI registers, register access permissions for IMPLEMENTATION DEFINED registers are IMPLEMENTATION DEFINED.

If ARMv8.3-DoPD is not implemented, the power domain of these registers is in which these registers are implemented is also IMPLEMENTATION DEFINED.

If ARMv8.3-DoPD is implemented, then:

- For debug registers and Performance Monitors registers, IMPLEMENTATION DEFINED registers are implemented in the Core power domain. Accesses return an error when the Core power domain is off or in a low-power state.
- For CTI registers, IMPLEMENTATION DEFINED registers are implemented in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses to registers. These constraints must also apply to IMPLEMENTATION DEFINED registers. In particular, if the OPTIONAL Software Lock is locked, writes are ignored and accesses have no side-effects. For more information see *Register access permissions for memory-mapped accesses* on page H8-6832.

H8.5.6 Reserved and unallocated registers

The default access requirements for reserved and unallocated registers are described in *Access requirements for reserved and unallocated registers* on page I1-7012.

Note

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is set, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- All reserved CTI registers.
- For the debug registers, and Performance Monitors registers, if the implementation is CoreSight architecture compliant, and either ARMv8.3-DoPD is not implemented or the Core power domain is on, all reserved registers in the range `0xF00 - 0xFFC`. See *Management register access permissions* on page K2-7656.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.
2. For reserved debug registers and Performance Monitors registers, if ARMv8.3-DoPD is implemented, and the Core power domain is off or in a low-power state, the response is an error. Otherwise the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:

   Off The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DLK ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.

OSLK OSLSR.OSLK == 1. The OS Lock is locked.

3. In addition, for reserved debug registers in the address ranges `0x400 - 0x4FC` and `0x800 - 0x8FC`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EDAD `AllowExternalDebugAccess()` == FALSE. External debug is disabled.

   Note

   See also *Behavior of a not permitted access* on page H8-6836.

4. In addition, for reserved Performance Monitors registers in the address ranges `0x000 - 0xEFC`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EPMAD `AllowExternalPMUAccess()` == FALSE. External Performance Monitor access is disabled.

   Note

   See also *Behavior of a not permitted access* on page H8-6836.

5. For reads of WO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a write to the location to return an error.

6. For writes of RO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a read to the location to return an error.

7. For reads and writes of locations for features that are not implemented, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires an access to the location to return an error if the feature is implemented.

H8.6 External debug interface registers

The external debug interface register map is described by:

- *Performance Monitors external register views* on page I5-7036.
- *Cross-trigger interface registers* on page H8-6845.
- *External debug interface register map*.

Table H8-2 External debug interface register map

a. Supported only if the OPTIONAL PC Sample-Based Profiling is implemented but ARMv8.2-PCSample is not implemented. See Chapter H7 *The PC Sample-based Profiling Extension*.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented.

b. A 64-bit register mapped to a pair of 32-bit locations. Doubleword accesses to this register are not guaranteed to be 64-bit single copy atomic. See *Endianness and supported access sizes* on page H8-6827. Software must ensure a breakpoint or watchpoint is disabled before altering the value register.

c. Implemented breakpoints and watchpoints only. *n* is the breakpoint or the watchpoint number.

Note

All other locations are reserved.

H8.6.1 Access permissions for the External debug interface registers

Table H8-3 on page H8-6842 and Table H8-4 on page H8-6843 show the access permissions for the external debug interface registers in an Armv8-A Debug implementation. The terms are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior. If ARMv8.3-DoPD is implemented, all External debug interface registers are in the Core power domain.

Conditions This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

Off The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed, and if ARMv8.3-DoPD is not implemented, EDPRSR.PU will read as 0.

Note

If debug power is off, then all external debug interface accesses return an error.

DLK ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE. The OS Double Lock is locked. If ARMv8.3-DoPD is implemented, ARMv8.0-DoubleLock is not implemented and so Table H8-3 on page H8-6842 does not include this column.

OSLK OSLSR.OSLK == 1. The OS Lock is locked.

EDAD `AllowExternalDebugAccess()` == FALSE. External debug access is disabled for the access. If ARMv8.4-Debug is implemented, this applies only for Non-secure accesses to the register. See also *Behavior of a not permitted access* on page H8-6836.

EPMAD `AllowExternalPMUAccess()` == FALSE. Access to the external Performance Monitors is disabled for the access. If ARMv8.4-Debug is implemented, this applies only for Non-secure accesses to the register. See also *Behavior of a not permitted access* on page H8-6836.

SLK The Software Lock is implemented and `SoftwareLockStatus()` == TRUE. This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-6832. For all other accesses, this column is ignored.

Default This provides the default access permissions, if there are no conditions that prevent access to the register.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO This means that the register or field is read-only, and:

- Unless the register description states otherwise, a RO field in an RW register ignores writes.
- Where the **SLK** control makes a RW register RO, the register ignores writes.

RW This means that the register or field is read/write. Individual fields within the register might be RO or WO. See the relevant register description for details.

RC This means that a read of the register bit clears the field to 0.

WO This means that the register or field is write-only. Unless the register description states otherwise, a WO field in a RW register returns an UNKNOWN value on a read of the register.

WI This means that the register or field ignores writes.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMP DEF This means that the access permissions are IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See *Register access permissions for memory-mapped accesses* on page H8-6832.

For the reset values for the external debug interface registers, see Table H8-7 on page H8-6848.

0xFC8	EDDEVID	Debug	Error	-	-	-	RO	RO

a. Implemented only if the PC Sample-based profiling Extension is implemented.

b. If ARMv8.2-Debug is not implemented, it is IMPLEMENTATION DEFINED whether an error is returned. See *External access disabled* on page H8-6835. If no error is returned, the access is permitted.

c. Some bits are in the Debug power domain and some bits are in the Core power domain. See register field descriptions for information.

d. Implemented breakpoints and watchpoints only. *n* is the breakpoint or watchpoint number.

e. It is IMPLEMENTATION DEFINED whether an error is returned. See *External debug over powerdown and locks* on page H8-6835. If no error is returned, the access is permitted.

H8.7 Cross-trigger interface registers

The embedded Cross-trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block for each PE.

If the CTI of a PE does not implement the CTIDEVAFF0 or CTIDEVAFF1 registers it must be located 64KB above the debug registers in the external debug interface.

When ARMv8.4-Debug is implemented, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

Table H8-5 shows the CTI register map.

Table H8-5 Cross-trigger interface map

H8.8 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

A reset might change the value of a register. Specific rules apply to the observability of registers in the External Debug reset domain by indirect reads from the Core power domain when an External Debug reset is asserted without a coincident Cold reset. For more information, see *Synchronization of changes to the external debug registers* on page H8-6828.

Table H8-7 on page H8-6848 and Table H8-8 on page H8-6849 show the external debug register and CTI register resets. For other debug registers and Performance Monitors registers, see *Management register resets* on page K2-7660 and *Power domains and Performance Monitors registers reset* on page I3-7029.

Note

By reference to Figure H6-1 on page H6-6819 the power domain can be deduced from the reset domain. Table K2-7 on page K2-7660 also shows reset power domains.

Table H8-7 on page H8-6848 and Table H8-8 on page H8-6849 do not include:

- Read-only identification registers, such as Processor ID Registers and PMCFGR, that have a fixed value from reset.
- Read-only status registers, such as EDSCR.RW, that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as EDRCR, that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and EDPRCR.CORENPDRQ, that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value, that can be UNKNOWN. The register is in the specified reset domain.

Note

An IMPLEMENTATION DEFINED reset value, which can be UNKNOWN, means that hardware is not required to reset the register on the specified reset, but software must not rely on the register being preserved over reset.

Table H8-7 Summary of external debug register resets, debug registers

Register	Reset domain	Field	Value	Description
DBGPRCR_EL1	Cold into AArch64 state	CORENPRDRQ	The value of the powerup request [a]	Debug Power Control Register.
DBGPRCR	Cold into AArch32 state	CORENPRDRQ	The value of the powerup request [a]	Debug Power Control Register.
EDESR	Warm	SS	EDECR.SS	Halting Step debug event pending
		RC	EDECR.RCE	Reset Catch debug event pending
		OSUC	0	OS Unlock Catch debug event pending
EDESR if ARMv8.3-DoPD is implemented	Cold	SS	0	Halting Step debug event pending
	Warm	RC	CTIDEVCTL .RCE	Reset Catch debug event pending
EDECR if ARMv8.3-DoPD is implemented	Cold	SS	0	Halting Step debug event enable
EDECR if ARMv8.3-DoPD is not implemented	External debug	SS	0	Halting Step debug event enable
		RCE	0	Reset Catch debug event enable
		OSUCE	0	OS Unlock Catch debug event enable
EDWAR	Cold	-	-	All fields
EDSCR	Cold	RXfull	0	DTRRX register full
		TXfull	0	DTRTX register full
		RXO	0	DTRRX overrun
		TXU	0	DTRTX underrun
		INTdis	0	Interrupt disable
		TDA	0	Trap debug register accesses to Debug state
		MA	0	Memory access mode in Debug state
		HDE	0	Halting debug mode enable
		ERR	0	Cumulative error flag
EDECCR	Cold	NSE[2:1]	`0b00`	Coarse-grained Non-secure Exception Catch
		SE[3,1]	`0b00`	Coarse-grained Secure Exception Catch
EDPCSR	Cold	-	-	All fields
EDCIDSR	Cold	-	-	All fields
EDVIDSR	Cold	-	-	All fields

Table H8-7 Summary of external debug register resets, debug registers (continued)

Register	Reset domain	Field	Value	Description
EDPRCR if ARMv8.3-DoPD is implemented	Cold	-	-	-
EDPRCR if ARMv8.3-DoPD is not implemented	External debug	COREPURQ[b]	-	Core powerup request
EDPRSR	Warm	SDR	-	Sticky debug restart
	Cold	SPMAD	0	Sticky EPMAD error
		SDAD	0	Sticky EDAD error
	Warm	SR	1	Sticky reset status
	Cold	SPD	1	Sticky powerdown status

a. If ARMv8.3-DoPD is not implemented, the powerup request is the EDPRCR.COREPURQ control bit.

b. If ARMv8.3-DoPD is not implemented, on a Cold reset into AArch64 state, DBGPRCR_EL1.CORENPRDRQ resets to the value of EDPRCR.COREPURQ. On a Cold reset into AArch32 state, DBGPRCR.CORENPRDRQ resets to the value of EDPRCR.COREPURQ. If an External Debug reset and a Cold reset coincide, both EDPRCR.COREPURQ and the CORENPRDRQ field of the appropriate System register are reset to 0.

Table H8-8 shows the reset values for the CTI registers

Table H8-8 Summary of external debug register resets, CTI registers

Register	Reset domain	Field	Value	Description
CTICONTROL	External debug	GLBEN	0	CTI global enable
CTIDEVCTL	External debug	RCE	0	If ARMv8.3-DoPD is implemented, Reset Catch debug event enable
		OSUCE	0	If ARMv8.3-DoPD is implemented, OS Unlock Catch debug event enable
CTIAPPSET	External debug	-	-	All fields
CTIINEN<n>	External debug	-	-	All fields
CTIOUTEN<n>	External debug	-	-	All fields
CTIGATE	External debug	-	-	All fields
ASICCTL	IMPLEMENTATION DEFINED	-	IMPLEMENTATION DEFINED	All of register

Chapter H9
External Debug Register Descriptions

This chapter provides a description of the external debug registers.

It contains the following sections:

- *About the debug registers* on page H9-6852.
- *External debug registers* on page H9-6853.
- *Cross-Trigger Interface registers* on page H9-6960.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.1 About the debug registers

The following sections describe the registers that are accessible through the external debug interface:

- *External debug registers* on page H9-6853.
- *Cross-Trigger Interface registers* on page H9-6960.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2 External debug registers

This section describes the debug registers that are accessible through the external debug interface and are used for external debug.

This section lists the registers that are accessible through the external debug interface.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Configurations

External register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1[31:0].

External register DBGAUTHSTATUS_EL1[31:0] is architecturally mapped to AArch32 System register DBGAUTHSTATUS[31:0].

It is IMPLEMENTATION DEFINED whether DBGAUTHSTATUS_EL1 is implemented in the Core power domain or in the Debug power domain.

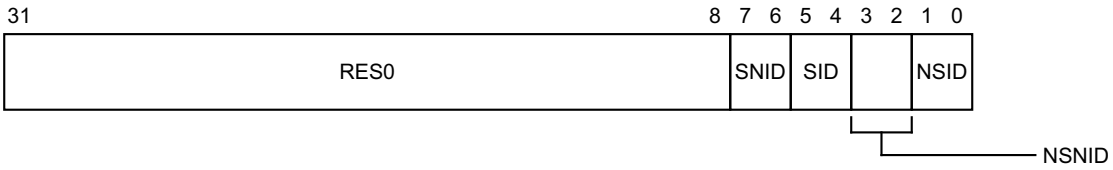
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS_EL1 bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

When ARMv8.4-Debug is implemented:

Secure non-invasive debug.

ExternalSecureNoninvasiveDebugEnabled() == ExternalSecureInvasiveDebugEnabled().

This field has the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise:

Secure non-invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.

`0b10` Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

SID, bits [5:4]

Secure invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 1.

`0b10` Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

NSNID, bits [3:2]

When ARMv8.4-Debug is implemented:

Non-secure non-invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.

`0b11` Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

If the Effective value of SCR_EL3.NS is 1, or if EL3 is implemented and EL2 is not implemented, this field reads as `0b11`.

All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.

`0b10` Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

`0b00` Not implemented. EL3 is not implemented and the Effective value of SCR_EL3.NS is 0.

`0b10` Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.

`0b11` Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

All other values are reserved.

Accessing the DBGAUTHSTATUS_EL1:

DBGAUTHSTATUS_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFB8`	DBGAUTHSTATUS_EL1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Configurations

External register DBGBCR<n>_EL1[31:0] is architecturally mapped to AArch64 System register DBGBCR<n>_EL1[31:0].

External register DBGBCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBCR<n>[31:0].

DBGBCR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then accesses to this register are:

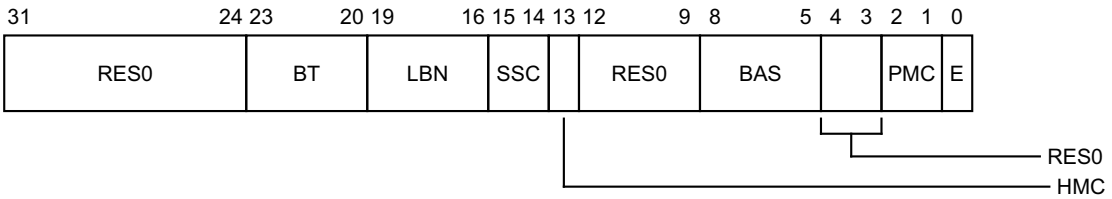
- RES0 when IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess().
- A CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR otherwise.

Attributes

DBGBCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGBCR<n>_EL1 bit assignments are:



When the E field is zero, all the other fields in the register are ignored.

Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

`0b0000` Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.

`0b0001` As `0b0000` but linked to a Context matching breakpoint.

`0b0010` Unlinked Context ID match. When ARMv8.1-VHE is implemented, EL2 is using AArch64, and the Effective value of HCR_EL2.E2H is 1, if either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL2 value. Otherwise, DBGBVR<n>_EL1.ContextID must match the CONTEXTIDR_EL1 value.

`0b0011` As `0b0010`, with linking enabled.

`0b0100` Unlinked instruction address mismatch. DBGBVR<n>_EL1 is the address of an instruction to be stepped.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b0101` As `0b0100`, with linking enabled.

`0b0110` Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.

`0b0111` As `0b0110`, with linking enabled.

`0b1000` Unlinked VMID match. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.

`0b1001` As `0b1000`, with linking enabled.

`0b1010` Unlinked VMID and Context ID match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.

`0b1011` As `0b1010`, with linking enabled.

`0b1100` Unlinked CONTEXTIDR_EL2 match. DBGBVR<n>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.

`0b1101` As `0b1100`, with linking enabled.

`0b1110` Unlinked Full Context ID match. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.ContextID2 is compared against CONTEXTIDR_EL2.

`0b1111` As `0b1110`, with linking enabled.

Constraints on breakpoint programming mean some values are reserved under certain conditions.

For more information on the operation of the SSC, HMC, and PMC fields, and on the effect of programming this field to a reserved value, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422 and *Reserved DBGBCR<n>_EL1.BT values* on page D2-2427.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of DBGBCR<n>_EL1.E is 0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values* on page D2-2427.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see DBGBCR<n>_EL1.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64 only implementation, this field is reserved, RES1.

The permitted values depend on the breakpoint type.

For Address match breakpoints in either AArch32 or AArch64 state, the permitted values are:

BAS	Match instruction at	Constraint for debuggers
0b0011	DBGBVR<n>_EL1	Use for T32 instructions
0b1100	DBGBVR<n>_EL1 + 2	Use for T32 instructions
0b1111	DBGBVR<n>_EL1	Use for A64 and A32 instructions

All other values are reserved.

For more information, see *Using the BAS field in Address Match breakpoints* on page G2-5641.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

BAS	Match instruction at	Constraint for debuggers
0b0000	-	Use for a match anywhere breakpoint
0b0011	DBGBVR<n>_EL1	Use for stepping T32 instructions
0b1100	DBGBVR<n>_EL1 + 2	Use for stepping T32 instructions
0b1111	DBGBVR<n>_EL1	Use for stepping A64 and A32 instructions

For more information, see *Using the BAS field in Address Match breakpoints* on page G2-5641.

For Context matching breakpoints, this field is RES1 and ignored.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>_EL1.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page D2-2422.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable breakpoint DBGBVR<n>_EL1. Possible values are:

0b0 Breakpoint disabled.

0b1 Breakpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the DBGBCR<n>_EL1:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGBCR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x408 + 16n	DBGBCR<n>_EL1

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1.

Configurations

External register DBGBVR<n>_EL1[63:0] is architecturally mapped to AArch64 System register DBGBVR<n>_EL1[63:0].

External register DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGBVR<n>[31:0].

If the breakpoint is context-aware and EL2 is implemented then External register DBGBVR<n>_EL1[63:32] is architecturally mapped to AArch32 System register DBGBXVR<n>[31:0]. Otherwise there is no External register access to DBGBVR<n>_EL1[63:32] from AArch32 state.

DBGBVR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then accesses to this register are:

- RES0 when IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess().
- A CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR otherwise.

Attributes

How this register is interpreted depends on the value of DBGBCR<n>_EL1.BT.

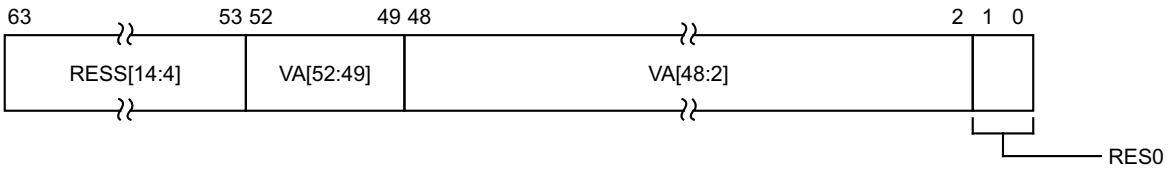
- When DBGBCR<n>_EL1.BT is `0b0x0x`, this register holds a virtual address.
- When DBGBCR<n>_EL1.BT is `0b001x`, `0b011x`, or `0b110x`, this register holds a Context ID.
- When DBGBCR<n>_EL1.BT is `0b100x`, this register holds a VMID.
- When DBGBCR<n>_EL1.BT is `0b101x`, this register holds a VMID and a Context ID.
- When DBGBCR<n>_EL1.BT is `0b111x`, this register holds two Context ID values.

For other values of DBGBCR<n>_EL1.BT, this register is RES0.

Field descriptions

The DBGBVR<n>_EL1 bit assignments are:

When DBGBCR<n>_EL1.BT == 0b0x0x:



RESS[14:4], bits [63:53]

Reserved, Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA[52:49], bits [52:49]

When ARMv8.2-LVA is implemented:

Extension to VA[48:2]. See VA[48:2] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Extension to RESS[14:4]. See RESS[14:4] for more details.

VA[48:2], bits [48:2]

If the address is being matched in an AArch64 stage 1 translation regime:

- This field contains bits[48:2] of the address for comparison.
- When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value. Otherwise, VA[52:49] are RESS.

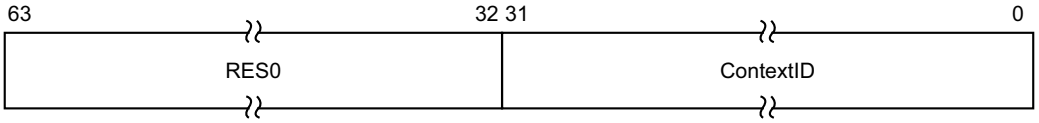
If the address is being matched in an AArch32 stage 1 translation regime, the first 20 bits of this field are RES0, and the rest of the field contains bits[31:2] of the address for comparison.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b001x:



Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

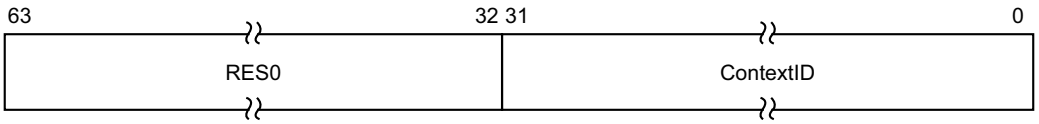
The value is compared against CONTEXTIDR_EL2 when ARMv8.1-VHE is implemented, EL2 is using AArch64, HCR_EL2.E2H is 1, and either:

- The PE is executing at EL2.
- HCR_EL2.TGE is 1, the PE is executing at EL0, and EL2 is enabled in the current Security state.

Otherwise, the value is compared against CONTEXTIDR when the PE is executing at AArch32, or CONTEXTIDR_EL1 when the PE is executing at AArch64.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT == 0b011x:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

When ARMv8.1-VHE is implemented:

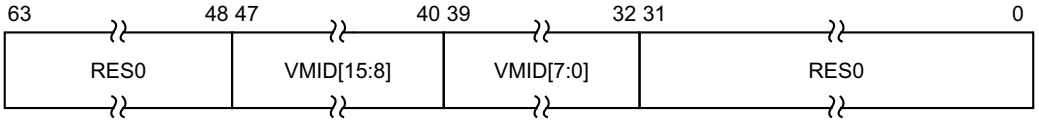
Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b100x and HaveEL(EL2):



Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When ARMv8.1-VHE is implemented:

Extension to VMID[7:0]. See VMID[7:0] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

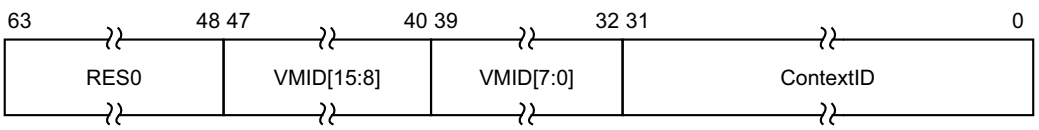
- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT == 0b101x and HaveEL(EL2):



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When ARMv8.1-VMID16 is implemented:

Extension to VMID[7:0]. See VMID[7:0] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- ARMv8.1-VMID16 is not implemented.

When ARMv8.1-VMID16 is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- VTCR_EL2.VS has a value of 0.
- EL2 is using AArch32.

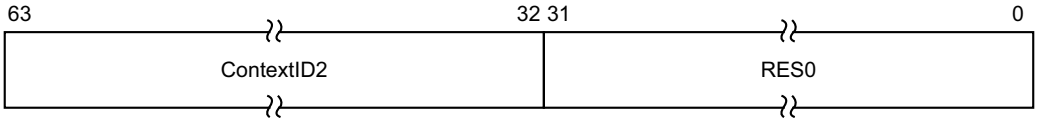
On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT == 0b110x and HaveEL(EL2):



ContextID2, bits [63:32]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

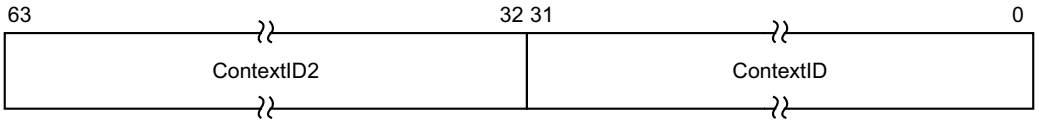
Reserved, RES0.

Bits [31:0]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When DBGBCR<n>_EL1.BT == 0b111x and HaveEL(EL2):



ContextID2, bits [63:32]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL2.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ContextID, bits [31:0]

When ARMv8.1-VHE is implemented:

Context ID value for comparison against CONTEXTIDR_EL1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing the DBGBVR<n>_EL1:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGBVR<n>_EL1[63:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	0x400 + 16n	DBGBVR<n>_EL1	63:0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET_EL1 register.

Configurations

External register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1[31:0].

External register DBGCLAIMCLR_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMCLR[31:0].

DBGCLAIMCLR_EL1 is in the Core power domain.

This register is not affected by a Warm reset, and is not affected by an External debug reset.

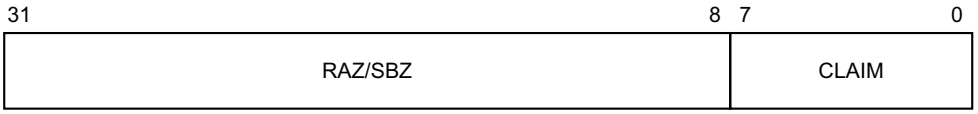
An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMCLR_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

On a Cold reset, this field resets to `0`.

Accessing the DBGCLAIMCLR_EL1:

DBGCLAIMCLR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFA4`	DBGCLAIMCLR_EL1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR_EL1 register.

Configurations

External register DBGCLAIMSET_EL1[31:0] is architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[31:0].

External register DBGCLAIMSET_EL1[31:0] is architecturally mapped to AArch32 System register DBGCLAIMSET[31:0].

DBGCLAIMSET_EL1 is in the Core power domain.

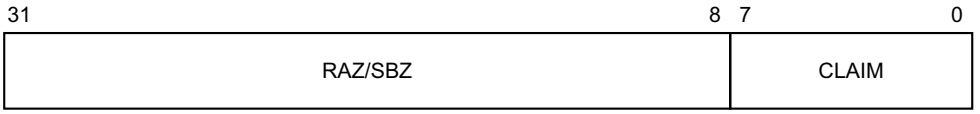
An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

Accessing the DBGCLAIMSET_EL1:

DBGCLAIMSET_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFA0	DBGCLAIMSET_EL1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Non-Confidential

H9.2.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

Configurations

External register DBGDTRRX_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0].

External register DBGDTRRX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRRXint[31:0].

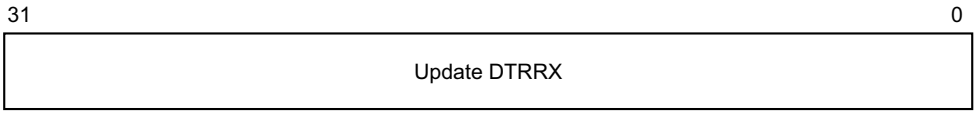
DBGDTRRX_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:



Bits [31:0]

Update DTRRX.

Writes to this register:

- If RXfull is set to 1, set DTRRX to UNKNOWN.
- If RXfull is set to 0, update the value in DTRRX.

After the write, RXfull is set to 1.

Reads of this register:

- If RXfull is set to 1, return the last value written to DTRRX.
- If RXfull is set to 0, return an UNKNOWN value.

After the read, RXfull remains unchanged.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGDTRRX_EL0:

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTRRX_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x080	DBGDTRRX_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.7 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

Configurations

External register DBGDTRTX_EL0[31:0] is architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0].

External register DBGDTRTX_EL0[31:0] is architecturally mapped to AArch32 System register DBGDTRTXint[31:0].

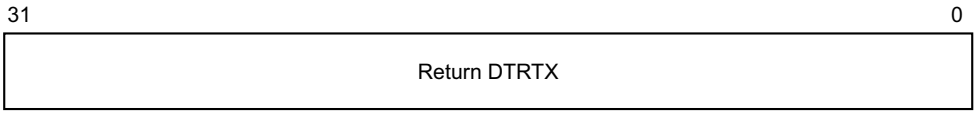
DBGDTRTX_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:



Bits [31:0]

Return DTRTX.

Reads of this register:

- If TXfull is set to 1, return the last value written to DTRTX.
- If TXfull is set to 0, return an UNKNOWN value.

After the read, TXfull is cleared to 0.

Writes to this register:

- If TXfull is set to 1, set DTRTX to UNKNOWN.
- If TXfull is set to 0, update the value in DTRTX.

After the write, TXfull remains unchanged.

For the full behavior of the Debug Communications Channel, see Chapter H4 *The Debug Communication Channel and Instruction Transfer Register*.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGDTRTX_EL0:

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTRTX_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x08C	DBGDTRTX_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.8 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

Configurations

External register DBGWCR<n>_EL1[31:0] is architecturally mapped to AArch64 System register DBGWCR<n>_EL1[31:0].

External register DBGWCR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWCR<n>[31:0].

DBGWCR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If watchpoint n is not implemented then accesses to this register are:

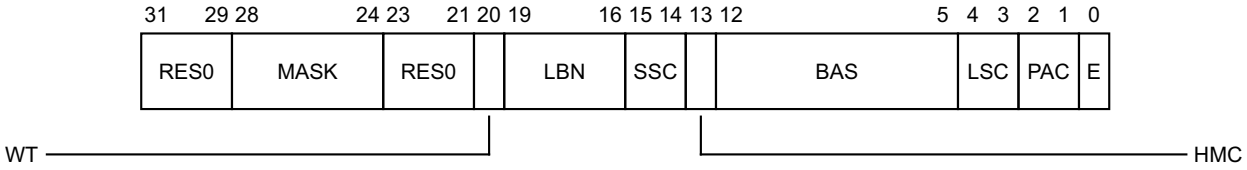
- When IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess(), RES0.
- Otherwise, a CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR.

Attributes

DBGWCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGWCR<n>_EL1 bit assignments are:



When the E field is zero, all the other fields in the register are ignored.

Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`0b00000` No mask.

`0b00001` Reserved.

`0b00010` Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from `0b00011` masking 3 address bits (`0x00000007` mask for address) to `0b11111` masking 31 address bits (`0x7FFFFFFF` mask for address).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

`0b0` Unlinked data address match.

`0b1` Linked data address match.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page D2-2433.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page D2-2433.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1 + 1
xxxxx1xx	Match byte at DBGWVR<n>_EL1 + 2
xxxx1xxx	Match byte at DBGWVR<n>_EL1 + 3

In cases where DBGWVR<n>_EL1 addresses a double-word:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1 + 4
xx1xxxxx	Match byte at DBGWVR<n>_EL1 + 5
x1xxxxxx	Match byte at DBGWVR<n>_EL1 + 6
1xxxxxxx	Match byte at DBGWVR<n>_EL1 + 7

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] is used. Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

The valid values for BAS are non-zero binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software. See *Reserved DBGWCR<n>.BAS values* on page G2-5663.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

`0b01` Match instructions that load from a watchpointed address.

`0b10` Match instructions that store to a watchpointed address.

`0b11` Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see *Execution conditions for which a watchpoint generates Watchpoint exceptions* on page D2-2433.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint n. Possible values are:

`0b0` Watchpoint disabled.

`0b1` Watchpoint enabled.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the DBGWCR<n>_EL1:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGWCR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0x808` + 16n	DBGWCR<n>_EL1

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.9 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1.

Configurations

External register DBGWVR<n>_EL1[63:0] is architecturally mapped to AArch64 System register DBGWVR<n>_EL1[63:0].

External register DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register DBGWVR<n>[31:0].

DBGWVR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If watchpoint n is not implemented then accesses to this register are:

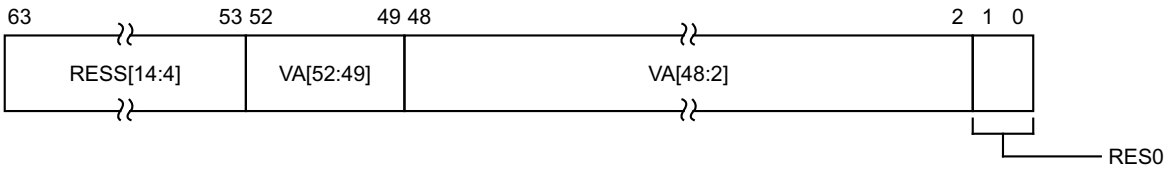
- When IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess(), RES0.
- Otherwise, a CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:



RESS[14:4], bits [63:53]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA[52:49], bits [52:49]

When ARMv8.2-LVA is implemented:

Extension to VA[48:2]. See VA[48:2] for more details.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Extension to RESS[14:4]. See RESS[14:4] for more details.

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When ARMv8.2-LVA is implemented, VA[52:49] forms the upper part of the address value. Otherwise, VA[52:49] are RESS.

Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>_EL1:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGWVR<n>_EL1[63:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	0x800 + 16n	DBGWVR<n>_EL1	63:0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.10 EDAA32PFR, External Debug AArch32 Processor Feature Register

The EDAA32PFR characteristics are:

Purpose

Provides information about implemented PE features.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D13-2823.

Configurations

It is IMPLEMENTATION DEFINED whether EDAA32PFR is implemented in the Core power domain or in the Debug power domain.

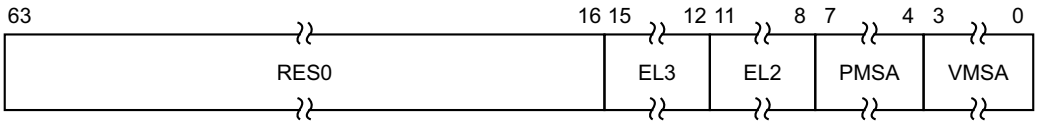
EDAA32PFR is only accessible in an implementation that only supports execution in AA32 state. If AArch64 state is supported at any Exception level, EDAA32PFR is RES0.

Attributes

EDAA32PFR is a 64-bit register.

Field descriptions

The EDAA32PFR bit assignments are:



Bits [63:16]

Reserved, RES0.

EL3, bits [15:12]

AArch32 EL3 Exception level handling. Defined values are:

`0b0000` EL3 is not implemented.

`0b0001` EL3 can be executed in AArch32 state only.

When the value of EDPFR.EL3 is non-zero, this field must be `0b0000`.

All other values are reserved.

Note

EDPFR.{EL1, EL0} indicate whether EL1 and EL0 can only be executed in AArch32 state.

EL2, bits [11:8]

AArch32 EL2 Exception level handling. Defined values are:

`0b0000` EL2 is not implemented.

`0b0001` EL2 can be executed in AArch32 state only.

When the value of EDPFR.EL2 is non-zero, this field must be `0b0000`.

All other values are reserved.

Note

EDPFR.{EL1, EL0} indicate whether EL1 and EL0 can only be executed in AArch32 state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMSA, bits [7:4]

Indicates support for a PMSA. Defined values are:

`0b0000` PMSA not supported.

`0b0100` Support for an Armv8-R PMSAv8-32.

All other values are reserved. In Armv8-A, the only permitted value is `0b0000`.

VMSA, bits [3:0]

Indicates support for a VMSA. When the PMSA field is nonzero, determines support for a VMSA. When the PMSA field is `0b0000`, VMSA is supported. Defined values are:

`0b0000` VMSA not supported.

All other values are reserved. In Armv8-A, the only permitted value is `0b0000`.

Accessing the EDAA32PFR:

EDAA32PFR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xD60`	EDAA32PFR

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() accesses to this register are RO.
- Otherwise accesses to this register are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.11 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

Purpose

Allows implementations to support IMPLEMENTATION DEFINED controls.

Configurations

It is IMPLEMENTATION DEFINED whether EDACR is implemented in the Core power domain or in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Changing this register from its reset value causes IMPLEMENTATION DEFINED behavior, including possible deviation from the architecturally-defined behavior.

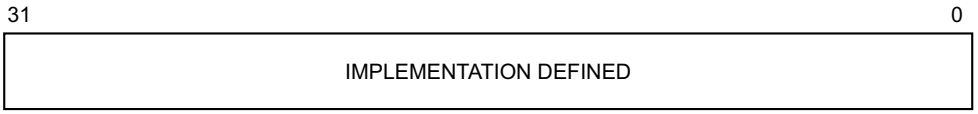
If the EDACR contains any control bits that must be preserved over power down, then these bits must be accessible by the external debug interface when the OS Lock is locked, OSLSR_EL1.OSLK == 1, and when the Core is powered off.

Attributes

EDACR is a 32-bit register.

Field descriptions

The EDACR bit assignments are:



IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

This field resets to an architecturally UNKNOWN value.

Accessing the EDACR:

EDACR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x094	EDACR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.12 EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether EDCIDR0 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

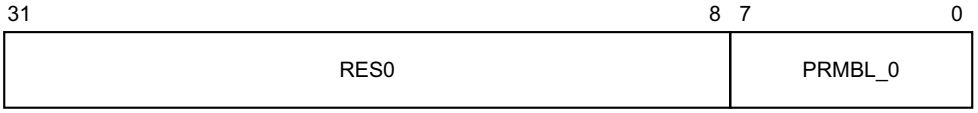
This register is required for CoreSight compliance.

Attributes

EDCIDR0 is a 32-bit register.

Field descriptions

The EDCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the EDCIDR0:

EDCIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFF0`	EDCIDR0

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.13 EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether EDCIDR1 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

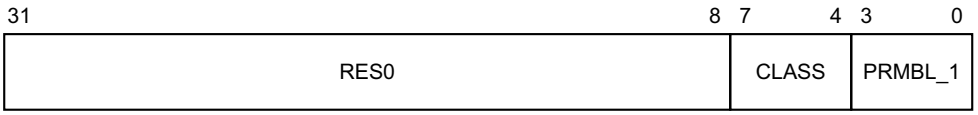
This register is required for CoreSight compliance.

Attributes

EDCIDR1 is a 32-bit register.

Field descriptions

The EDCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the EDCIDR1:

EDCIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFF4`	EDCIDR1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.14 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether EDCIDR2 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

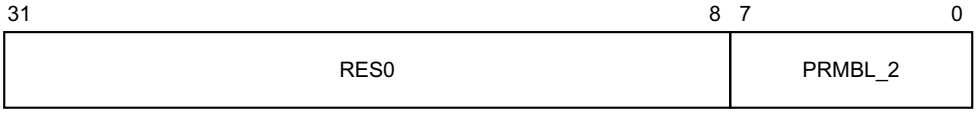
This register is required for CoreSight compliance.

Attributes

EDCIDR2 is a 32-bit register.

Field descriptions

The EDCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the EDCIDR2:

EDCIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFF8`	EDCIDR2

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.15 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether EDCIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

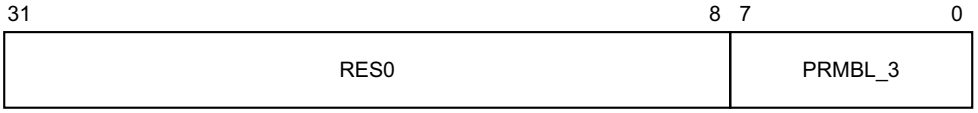
This register is required for CoreSight compliance.

Attributes

EDCIDR3 is a 32-bit register.

Field descriptions

The EDCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the EDCIDR3:

EDCIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFFC`	EDCIDR3

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.16 EDCIDSR, External Debug Context ID Sample Register

The EDCIDSR characteristics are:

Purpose

Contains the sampled value of the Context ID, captured on reading EDPCSR[31:0].

Configurations

EDCIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented in the external debug registers space.

Note

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors registers space.

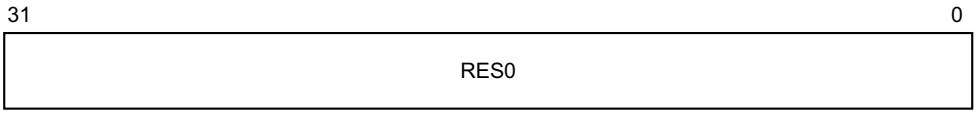
Attributes

EDCIDSR is a 32-bit register.

Field descriptions

The EDCIDSR bit assignments are:

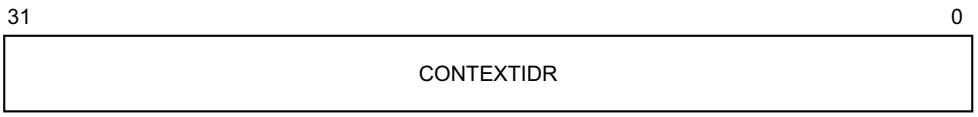
When ARMv8.2-PCSample is implemented:



Bits [31:0]

Reserved, RES0.

Otherwise:



CONTEXTIDR, bits [31:0]

Context ID. The value of CONTEXTIDR that is associated with the most recent EDPCSR sample.

- If EL1 is using AArch64, then the Context ID is held in CONTEXTIDR_EL1.
- If EL1 is using AArch32, then the Context ID is held in CONTEXTIDR.
- If EL3 is implemented and is using AArch32, then CONTEXTIDR is a banked register, and EDCIDSR samples the current banked copy of CONTEXTIDR for the Security state that is associated with the most recent EDPCSR sample.

Because the value written to EDCIDSR is an indirect read of CONTEXTIDR, therefore it is CONSTRAINED UNPREDICTABLE whether EDCIDSR is set to the original or new value if a read of EDPCSRlo samples:

- An instruction that writes to CONTEXTIDR_EL1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The next Context synchronization event.
- Any instruction executed between these two instructions.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the EDCIDSR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824.

EDCIDSR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x0A4	EDCIDSR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.17 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVAFF0 is implemented in the Core power domain or in the Debug power domain.

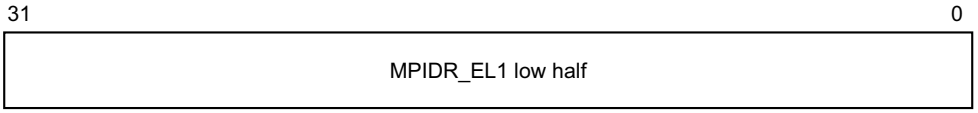
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDDEVAFF0 is a 32-bit register.

Field descriptions

The EDDEVAFF0 bit assignments are:



MPIDR_EL1 low half, bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the EDDEVAFF0:

EDDEVAFF0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFA8	EDDEVAFF0

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.18 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVAFF1 is implemented in the Core power domain or in the Debug power domain.

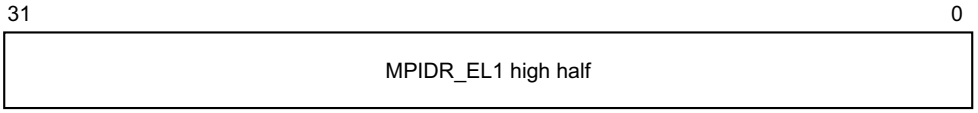
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDDEVAFF1 is a 32-bit register.

Field descriptions

The EDDEVAFF1 bit assignments are:



MPIDR_EL1 high half, bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the EDDEVAFF1:

EDDEVAFF1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFAC	EDDEVAFF1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.19 EDDEVARCH, External Debug Device Architecture register

The EDDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the external debug component.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVARCH is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

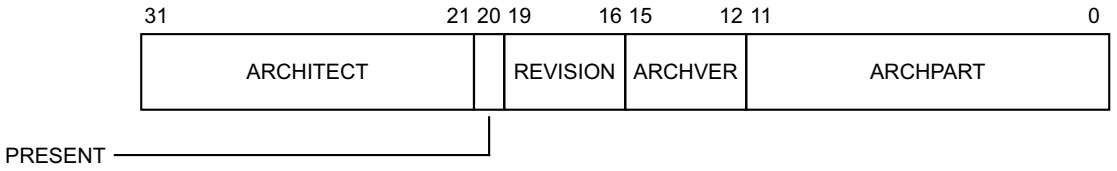
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDDEVARCH is a 32-bit register.

Field descriptions

The EDDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For debug, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, `0x4`.

Bits [27:21] are the JEP106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in Armv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

For debug, the revision defined by Armv8-A is `0x0`.

All other values are reserved.

ARCHVER, bits [15:12]

Defines the architecture version of the component. This is the same value as ID_AA64DFR0_EL1.DebugVer and DBGDIDR.Version. The defined values of this field are:

`0b0110` Armv8.0 Debug architecture.

`0b0111` Armv8.0 Debug architecture with Virtualization Host Extensions.

`0b1000` Armv8.2 Debug architecture.

`0b1001` Armv8.4 Debug architecture.

ARMv8.4-Debug adds the functionality indicated by the value `0b1001`.ARMv8.2-Debug adds the functionality indicated by the value `0b1000`. If ARMv8.1-VHE is not implemented, the only permitted value is `0b0110`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The fields ARCHVER and ARCHPART together form the field ARCHID, so that ARCHVER is ARCHID[15:12].

ARCHPART, bits [11:0]

`0xA15` The part number of the Armv8-A debug component.

The fields ARCHVER and ARCHPART together form the field ARCHID, so that ARCHPART is ARCHID[11:0].

Accessing the EDDEVARCH:

EDDEVARCH can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFBC`	EDDEVARCH

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.20 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVID is implemented in the Core power domain or in the Debug power domain.

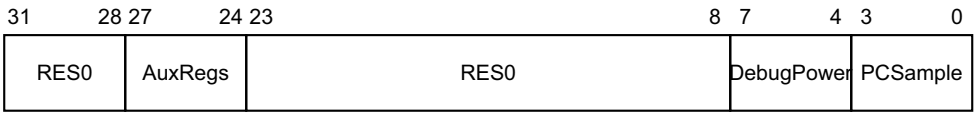
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDDEVID is a 32-bit register.

Field descriptions

The EDDEVID bit assignments are:



Bits [31:28]

Reserved, RES0.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

`0b0000` None supported.

`0b0001` Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

Bits [23:8]

Reserved, RES0.

DebugPower, bits [7:4]

From ARMv8.3:

Indicates support for the ARMv8.3-DoPD feature. Defined values of this field are:

`0b0000` ARMv8.3-DoPD not implemented. Registers in the external debug interface register map are implemented in a mix of the Debug and Core power domains.

`0b0001` ARMv8.3-DoPD implemented. All registers in the external debug interface register map are implemented in the Core power domain.

ARMv8.3-DoPD implements the functionality added by the value `0b0001`.

All other values are reserved.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using external debug registers. Permitted values of this field are:

`0b0000` PC Sample-based Profiling Extension is not implemented in the external debug registers space.

`0b0010` Only EDPCSR and EDCIDSR are implemented. This option is only permitted if EL3 and EL2 are not implemented.

`0b0011` EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

When ARMv8.2-PCSample is implemented, the only permitted value is `0b0000`.

Note

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Accessing the EDDEVID:

EDDEVID can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFC8`	EDDEVID

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.21 EDDEVID1, External Debug Device ID register 1

The EDDEVID1 characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVID1 is implemented in the Core power domain or in the Debug power domain.

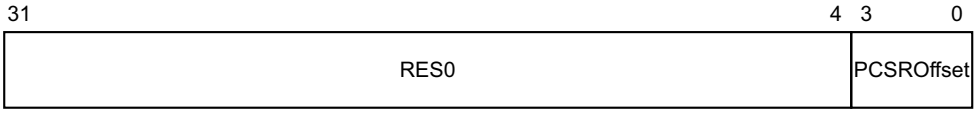
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDDEVID1 is a 32-bit register.

Field descriptions

The EDDEVID1 bit assignments are:



Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in Armv8 are:

`0b0000` EDPCSR not implemented.

`0b0010` EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

When ARMv8.2-PCSample is implemented, the only permitted value is `0b0000`.

Note

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Accessing the EDDEVID1:

EDDEVID1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFC4`	EDDEVID1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.22 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVID2 is implemented in the Core power domain or in the Debug power domain.

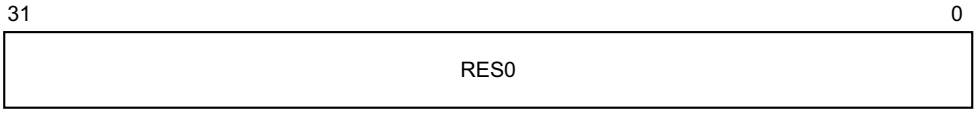
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDDEVID2 is a 32-bit register.

Field descriptions

The EDDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the EDDEVID2:

EDDEVID2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFC0	EDDEVID2

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.23 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PEs debug logic.

Configurations

It is IMPLEMENTATION DEFINED whether EDDEVTYPE is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

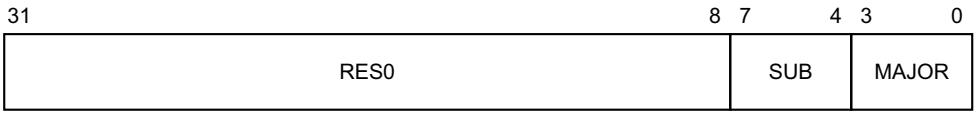
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDDEVTYPE is a 32-bit register.

Field descriptions

The EDDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as `0x5` to indicate this is a debug logic component.

Accessing the EDDEVTYPE:

EDDEVTYPE can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFCC`	EDDEVTYPE

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.24 EDDFR, External Debug Feature Register

The EDDFR characteristics are:

Purpose

Provides top level information about the debug system.

Note

Debuggers must use EDDEVARCH to determine the Debug architecture version.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D13-2823.

Configurations

It is IMPLEMENTATION DEFINED whether EDDFR is implemented in the Core power domain or in the Debug power domain.

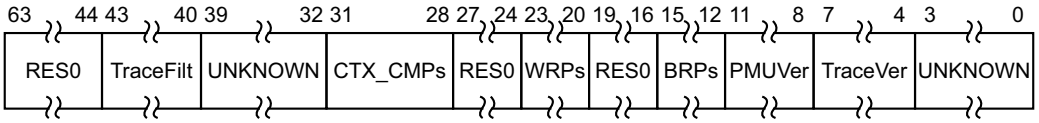
There are no configuration notes.

Attributes

EDDFR is a 64-bit register.

Field descriptions

The EDDFR bit assignments are:



Bits [63:44]

Reserved, RES0.

TraceFilt, bits [43:40]

From ARMv8.4:

Armv8.4 Self-hosted Trace Extension version. The defined values of this field are:

`0b0000` Armv8.4 Self-hosted Trace Extension is not implemented.

`0b0001` Armv8.4 Self-hosted Trace Extension is implemented.

All other values are reserved.

Otherwise:

Reserved, RES0.

UNKNOWN, bits [39:32]

Reserved, UNKNOWN.

CTX_CMPs, bits [31:28]

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.CTX_CMPs.

Bits [27:24]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of `0b0000` is reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.WRPs.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of `0b0000` is reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.BRPs.

PMUVer, bits [11:8]

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the Alternative ID scheme described in *Alternative ID scheme used for the Performance Monitors Extension version* on page D13-2825.

Defined values are:

`0b0000` Performance Monitors Extension not implemented.

`0b0001` Performance Monitors Extension implemented, PMUv3.

`0b0100` PMUv3 for Armv8.1. As `0b0001`, and also includes support for:

- Extended 16-bit PMEVTYPER<n>_EL0.evtCount field.
- If EL2 is implemented, the MDCR_EL2.HPMD control bit.

`0b0101` PMUv3 for Armv8.4. As `0b0100` and also includes support for the PMMIR register.

`0b0110` PMUv3 for Armv8.5. As `0b0101` and also includes support for:

- 64-bit event counters.
- If EL2 is implemented, the MDCR_EL2.HCCD control bit.
- If EL3 is implemented, the MDCR_EL3.SCCD control bit.

`0b1111` IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. Arm does not recommend this value in new implementations.

ARMv8.1-PMU implements the functionality added by the value `0b0100`.

ARMv8.4-PMU implements the functionality added by the value `0b0101`.

ARMv8.5-PMU implements the functionality added by the value `0b0110`.

All other values are reserved.

From Armv8.1, the value `0b0001` is not permitted.

From Armv8.4, the value `0b0100` is not permitted.

From Armv8.5, the value `0b0101` is not permitted.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.PMUVer.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a PE trace unit is implemented. Defined values are:

`0b0000` PE trace unit System registers not implemented.

`0b0001` PE trace unit System registers implemented.

All other values are reserved.

A value of `0b0000` only indicates that no System register interface to a PE trace unit is implemented. A PE trace unit might nevertheless be implemented without a System register interface.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64DFR0_EL1.TraceVer.

UNKNOWN, bits [3:0]

Reserved, UNKNOWN.

Accessing the EDDFR:

EDDFR[31:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	0xD28	EDDFR	31:0

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() accesses to EDDFR[31:0] are RO.
- Otherwise accesses to EDDFR[31:0] are IMPDEF.

EDDFR[63:32] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	0xD2C	EDDFR	63:32

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() accesses to EDDFR[63:32] are RO.
- Otherwise accesses to EDDFR[63:32] are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.25 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

Purpose

Controls Exception Catch debug events.

Configurations

External register EDECCR[31:0] is architecturally mapped to AArch64 System register OSECCR_EL1[31:0].

External register EDECCR[31:0] is architecturally mapped to AArch32 System register DBGOSECCR[31:0].

EDECCR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

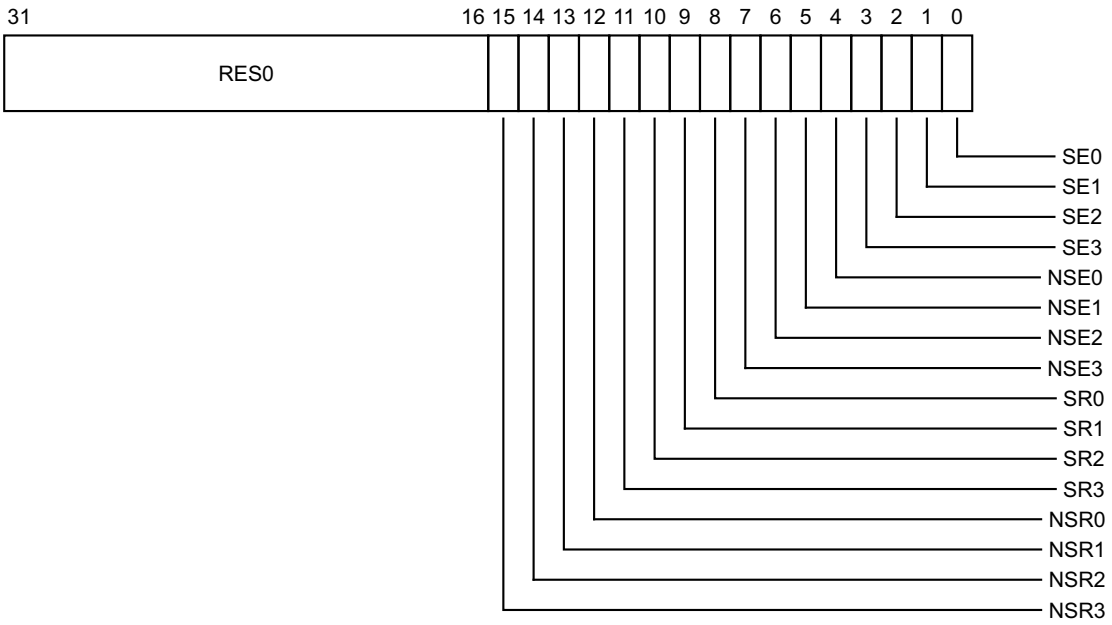
Attributes

EDECCR is a 32-bit register.

Field descriptions

The EDECCR bit assignments are:

When ARMv8.2-Debug is implemented:



Bits [31:16]

Reserved, RES0.

NSR<n>, bit [n+12], for n = 0 to 3

Controls Non-secure exception catch on exception return to EL<n> in conjunction with NSE<n>. See the Table H3-5 on page H3-6759 for information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

`0b0` If the corresponding NSE<n> bit is 0, then Exception Catch debug events are disabled for Non-secure Exception level <n>.

If the corresponding NSE<n> bit is 1, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Non-secure Exception level <n>.

`0b1` If the corresponding NSE<n> bit is 0, then Exception Catch debug events are enabled for exception returns to Non-secure Exception level <n>.

If the corresponding NSE<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure Exception level <n>.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level is permitted to generate an Exception Catch debug event.

A value of the NSR field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the NSR field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSR by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to `0`.

SR<n>, bit [n+8], for n = 0 to 3

Controls Secure exception catch on exception return to EL<n> in conjunction with SE<n>. See the Table H3-5 on page H3-6759 for information.

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

`0b0` If the corresponding SE<n> bit is 0, then Exception Catch debug events are disabled for Secure Exception level <n>.

If the corresponding SE<n> bit is 1, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Secure Exception level <n>.

`0b1` If the corresponding SE<n> bit is 0, then Exception Catch debug events are enabled for exception returns to Secure Exception level <n>.

If the corresponding SE<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure Exception level <n>.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level is permitted to generate an Exception Catch debug event.

A value of the SR field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the SR field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SR by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to `0`.

NSE<n>, bit [n+4], for n = 0 to 3

Coarse-grained Non-secure exception catch for EL<n>. This controls whether Exception Catch debug events are enabled for Non-secure EL<n>. This also controls:

- The behavior of exception catch on exception entry to EL<n>.
- The behavior of exception catch on exception return to EL<n> in conjunction with NSR<n>.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

`0b0` If the corresponding NSR<n> bit is 0, then Exception Catch debug events are disabled for Non-secure Exception level <n>.

If the corresponding NSR<n> bit is 1, then Exception Catch debug events are enabled for exception returns to Non-secure Exception level <n>.

`0b1` If the corresponding NSR<n> bit is 0, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Non-secure Exception level <n>.

If the corresponding NSR<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure Exception level <n>.

A value of the NSE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the NSE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSE by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to `0`.

SE<n>, bit [n], for n = 0 to 3

Coarse-grained Secure exception catch for EL<n>. This field controls whether Exception Catch debug events are enabled for Secure EL<n>.

- The behavior of exception catch on exception entry to EL<n>.
- The behavior of exception catch on exception return to EL<n> in conjunction with SR<n>.

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

`0b0` If the corresponding SR<n> bit is 0, then Exception Catch debug events are disabled for Secure Exception level <n>.

If the corresponding SR<n> bit is 1, then Exception Catch debug events are enabled for exception returns to Secure Exception level <n>.

`0b1` If the corresponding SR<n> bit is 0, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Secure Exception level <n>.

If the corresponding SR<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure Exception level <n>.

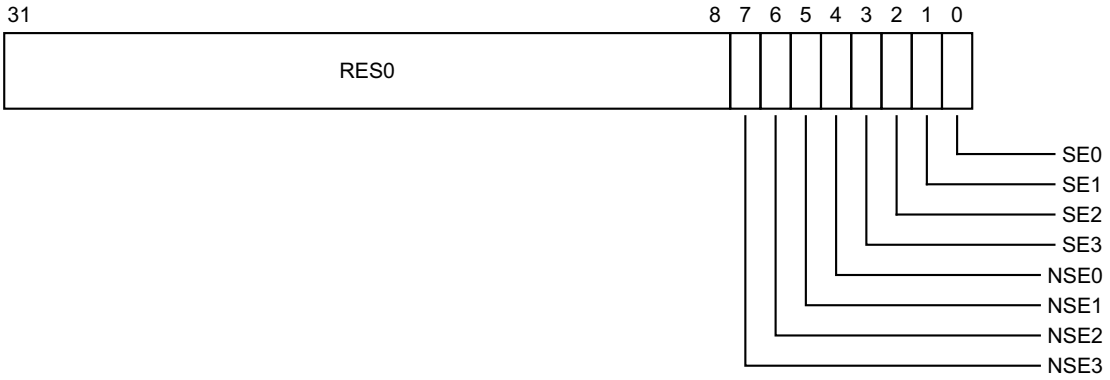
A value of the SE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the SE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SE by a read of EDECCR is UNKNOWN.

On a Cold reset, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:



Bits [31:8]

Reserved, RES0.

NSE<n>, bit [n+4], for n = 0 to 3

Coarse-grained Non-secure exception catch. If EL3 and EL2 are not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

`0b0` Exception Catch debug events are disabled for Non-secure Exception level <n>.

`0b1` Exception Catch debug events are enabled for Non-secure Exception level <n>.

A value of the NSE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the NSE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSE by a read of EDECCR is UNKNOWN.

SE<n>, bit [n], for n = 0 to 3

Coarse-grained Secure exception catch. If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

`0b0` Exception Catch debug events are disabled for Secure Exception level <n>.

`0b1` Exception Catch debug events are enabled for Secure Exception level <n>.

A value of the SE field that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If the SE field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SE by a read of EDECCR is UNKNOWN.

Accessing the EDECCR:

EDECCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0x098`	EDECCR

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

H9.2.26 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

Purpose

Controls Halting debug events.

Configurations

It is IMPLEMENTATION DEFINED whether EDECR is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

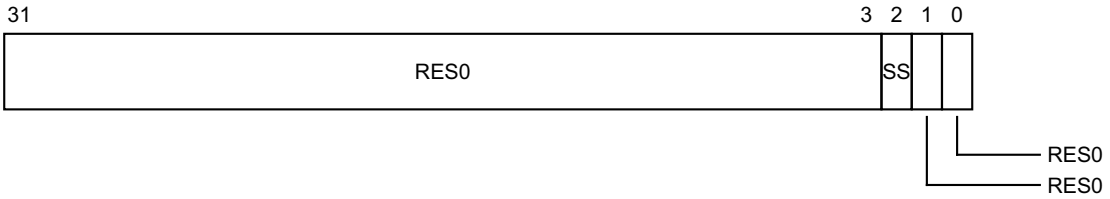
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

EDECR is a 32-bit register.

Field descriptions

The EDECR bit assignments are:



Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step enable. Possible values of this field are:

`0b0` Halting step debug event disabled.

`0b1` Halting step debug event enabled.

If the value of EDECR.SS is changed when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in *Changing the value of EDECR.SS when not in Debug state* on page H3-6753.

The following resets apply:

- On a Cold reset, if ARMv8.3-DoPD is implemented, this field resets to `0`.
- On a Debug reset, if ARMv8.3-DoPD is not implemented, this field resets to `0`.

Bit [1]

When ARMv8.3-DoPD is implemented:

Reserved, RES0.

Otherwise:

Reset Catch Enable.

`0b0` Reset Catch debug event disabled.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` Reset Catch debug event enabled.

On a External debug reset, this field resets to `0`.

Bit [0]

When ARMv8.3-DoPD is implemented:

Reserved, RES0.

Otherwise:

OS Unlock Catch Enable.

`0b0` OS Unlock Catch debug event disabled.

`0b1` OS Unlock Catch debug event enabled.

On a External debug reset, this field resets to `0`.

Accessing the EDECR:

EDECR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0x024`	EDECR

This interface is accessible as follows:

- When (ARMv8.3-DoPD is not implemented or IsCorePowered()) and SoftwareLockStatus() accesses to this register are RO.
- When (ARMv8.3-DoPD is not implemented or IsCorePowered()) and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.27 EDESR, External Debug Event Status Register

The EDESR characteristics are:

Purpose

Indicates the status of internally pending Halting debug events.

Configurations

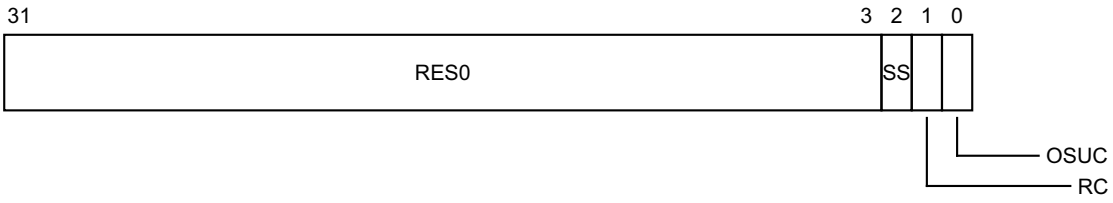
EDESR is in the Core power domain. Some or all RW fields of this register have defined reset values. The field descriptions identify when the reset values apply.

Attributes

EDESR is a 32-bit register.

Field descriptions

The EDESR bit assignments are:



Bits [31:3]

Reserved, RES0.

SS, bit [2]

When ARMv8.3-DoPD is implemented:

Halting step debug event pending. Possible values of this field are:

`0b0` Reading this means that a Halting step debug event is not pending. Writing this means no action.

`0b1` Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

On a Cold reset, this field resets to `0`.

Otherwise:

Halting step debug event pending. Possible values of this field are:

`0b0` Reading this means that a Halting step debug event is not pending. Writing this means no action.

`0b1` Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

On a Warm reset, this field resets to the value in EDECR.SS.

RC, bit [1]

Reset Catch debug event pending. Possible values of this field are:

`0b0` Reading this means that a Reset Catch debug event is not pending. Writing this means no action.

`0b1` Reading this means that a Reset Catch debug event is pending. Writing this clears the pending Reset Catch debug event.

On a Warm reset, this field resets to:

- If ARMv8.3-DoPD is implemented, this field resets to the value in CTIDEVCTL.RCE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Otherwise, this field resets to the value in EDECR.RCE.

OSUC, bit [0]

OS Unlock Catch debug event pending. Possible values of this field are:

`0b0` Reading this means that an OS Unlock Catch debug event is not pending. Writing this means no action.

`0b1` Reading this means that an OS Unlock Catch debug event is pending. Writing this clears the pending OS Unlock Catch debug event.

On a Warm reset, this field resets to `0`.

Accessing the EDESR:

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is CONSTRAINED UNPREDICTABLE whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it might become pending again when the Core is powered back on and Cold reset.

EDESR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0x020`	EDESR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.28 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configurations

It is IMPLEMENTATION DEFINED whether EDITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

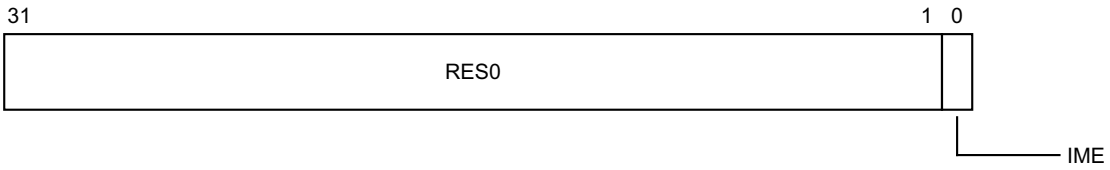
Implementation of this register is OPTIONAL.

Attributes

EDITCTRL is a 32-bit register.

Field descriptions

The EDITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0b0` Normal operation.

`0b1` Integration mode enabled.

On a Implementation reset, this field resets to `0`.

Accessing the EDITCTRL:

EDITCTRL can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xF00`	EDITCTRL

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.29 EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the PE for execution.

Configurations

EDITR is in the Core power domain.

There are no configuration notes.

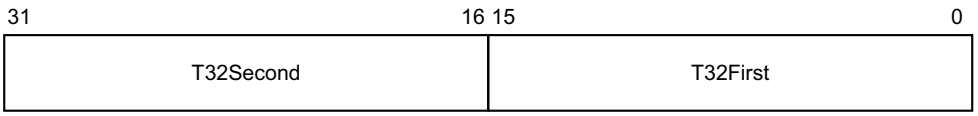
Attributes

EDITR is a 32-bit register.

Field descriptions

The EDITR bit assignments are:

When in AArch32 state:



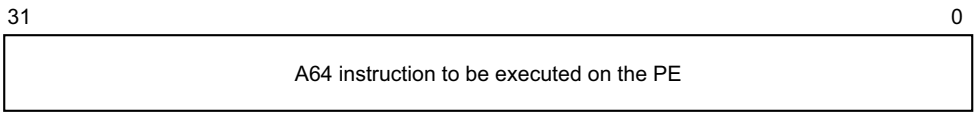
T32Second, bits [31:16]

Second halfword of the T32 instruction to be executed on the PE. When EDITR contains a 16-bit T32 instruction, this field is ignored. For more information see *Behavior in Debug state* on page H2-6714

T32First, bits [15:0]

First halfword of the T32 instruction to be executed on the PE.

When in AArch64 state:



Bits [31:0]

A64 instruction to be executed on the PE.

Accessing the EDITR:

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in Normal access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

EDITR ignores writes if the PE is in Non-debug state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EDITR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x084	EDITR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are WI.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are WO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.30 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

Purpose

Allows or disallows access to the external debug registers through a memory-mapped interface.

The optional Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Configurations

It is IMPLEMENTATION DEFINED whether EDLAR is implemented in the Core power domain or in the Debug power domain.

If ARMv8.4-Debug is implemented, the Software Lock is not implemented.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

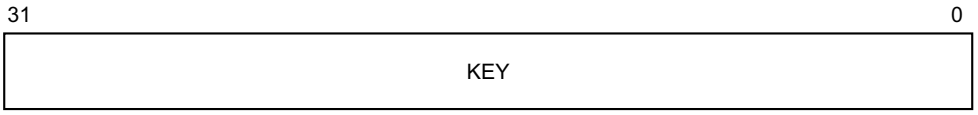
Attributes

EDLAR is a 32-bit register.

Field descriptions

The EDLAR bit assignments are:

When the Software Lock is implemented:

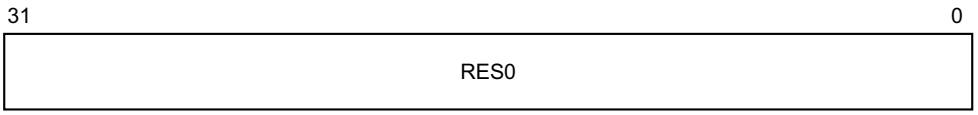


KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Otherwise:



Bits [31:0]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the EDLAR:

EDLAR can be accessed through its memory-mapped interface:

Component	Offset	Instance
Debug	0xFB0	EDLAR

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are WO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.31 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

Purpose

Indicates the current status of the software lock for external debug registers.

The optional Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Configurations

It is IMPLEMENTATION DEFINED whether EDLSR is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

If ARMv8.4-Debug is implemented, the Software Lock is not implemented.

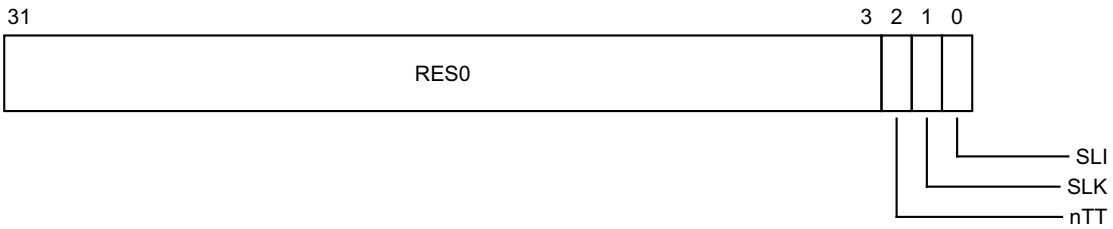
Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLSR is a 32-bit register.

Field descriptions

The EDLSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

When the Software Lock is implemented:

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the Software Lock is implemented, possible values of this field are:

`0b0` Lock clear. Writes are permitted to this component's registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

The following resets apply:

- If Armv8.3-DoPD is implemented, this register is reset by Cold reset and not affected by External debug reset. If Armv8.3-DoPD is not implemented, this register is reset by External debug reset and not affected by Cold reset.
- On a reset, this field resets to `1`.

Otherwise:

Reserved, RAZ.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0b0` Software Lock not implemented or not memory-mapped access.

`0b1` Software Lock implemented and memory-mapped access.

Accessing the EDLSR:

EDLSR can be accessed through its memory-mapped interface:

Component	Offset	Instance
Debug	`0xFB4`	EDLSR

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.32 EDPCSR, External Debug Program Counter Sample Register

The EDPCSR characteristics are:

Purpose

Holds a sampled instruction address value.

Configurations

EDPCSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented in the external debug registers space.

Note

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors registers space.

Attributes

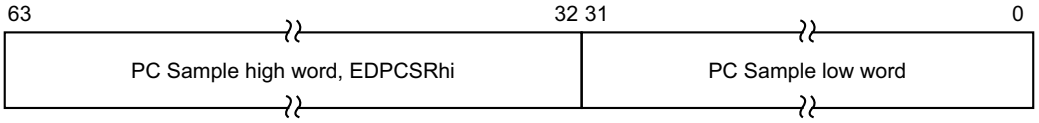
EDPCSR is a pair of 32-bit registers.

If ARMv8.1-VHE is implemented, the format of this register differs depending on the value of EDSCR.SC2.

Field descriptions

The EDPCSR bit assignments are:

When ARMv8.1-VHE is not implemented:



Bits [63:32]

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

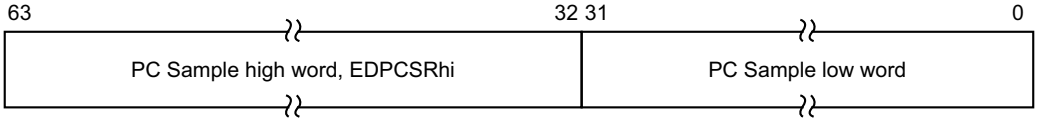
- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, EDCIDSR, and EDVIDSR:
  - If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF`, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
  - If the PE is in Reset state, the sampled value is UNKNOWN and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If no instruction has been sampled since the PE left Reset state, Debug state, or a state where PC Sample-based profiling is prohibited, the sampled value is `0xFFFFFFFF`, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN. Any subsequent read will return an instruction address value.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 0:



Bits [63:32]

When ARMv8.1-VHE is implemented:

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [31:0]

When ARMv8.1-VHE is implemented:

PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

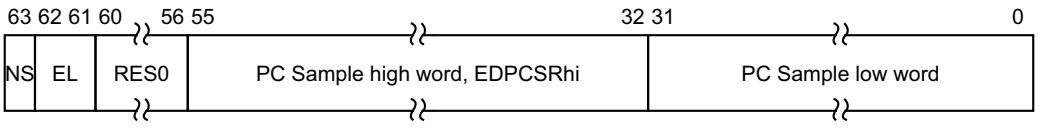
- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, EDCIDSR, and EDVIDSR:
  - — If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF`, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
  - — If the PE is in Reset state, the sampled value is UNKNOWN and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
  - — If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based profiling is prohibited, the sampled value is UNKNOWN, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 1:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NS, bit [63]

When ARMv8.1-VHE is implemented:

Non-secure state sample. Indicates the Security state that is associated with the most recent EDPCSR sample or, when it is read as a single atomic 64-bit read, the current EDPCSR sample. The translation regime that EDPCSR samples can be determined from EDPCSR.{NS,EL}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EL, bits [62:61]

When ARMv8.1-VHE is implemented:

Exception level status sample. Indicates the Exception level that is associated with the most recent EDPCSR sample or, when it is read as a single atomic 64-bit read, the current EDPCSR sample. The translation regime that EDPCSR samples can be determined from EDPCSR.{NS,EL}.

`0b00` Sample is from EL0.

`0b01` Sample is from EL1.

`0b10` Sample is from EL2.

`0b11` Sample is from EL3.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [60:56]

Reserved, RES0.

Bits [55:32]

When ARMv8.1-VHE is implemented:

PC Sample high word, EDPCSRhi. Bits [55:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDPCSR.{NS,EL}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [31:0]

When ARMv8.1-VHE is implemented:

PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, EDCIDSR, and EDVIDSR:
  - — If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF`, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
  - — If the PE is in Reset state, the sampled value is UNKNOWN and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
  - — If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based profiling is prohibited, the sampled value is UNKNOWN, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.

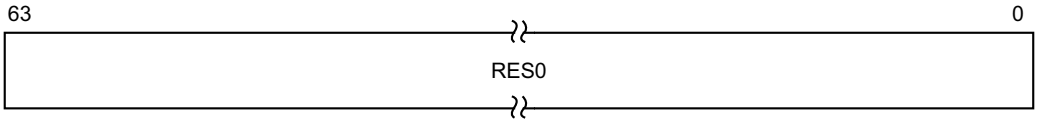
On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

When ARMv8.2-PCSample is implemented:



Bits [63:0]

Reserved, RES0.

Accessing the EDPCSR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824

EDPCSR[31:0] can be accessed through its memory-mapped interface:

Component	Offset	Instance	Range
Debug	0x0A0	EDPCSR	31:0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to EDPCSR[31:0] are RO.
- Otherwise accesses to EDPCSR[31:0] generate an error response.

EDPCSR[63:32] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	0x0AC	EDPCSR	63:32

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to EDPCSR[63:32] are RO.
- Otherwise accesses to EDPCSR[63:32] generate an error response.

H9.2.33 EDPFR, External Debug Processor Feature Register

The EDPFR characteristics are:

Purpose

Provides information about implemented PE features.

For general information about the interpretation of the ID registers, see *Principles of the ID scheme for fields in ID registers* on page D13-2823.

Configurations

It is IMPLEMENTATION DEFINED whether EDPFR is implemented in the Core power domain or in the Debug power domain.

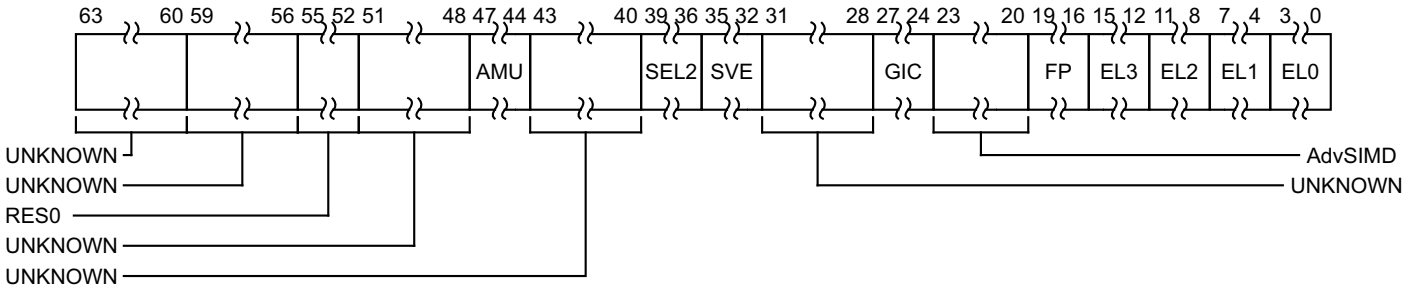
There are no configuration notes.

Attributes

EDPFR is a 64-bit register.

Field descriptions

The EDPFR bit assignments are:



UNKNOWN, bits [63:60]

From ARMv8.5:

Reserved, UNKNOWN.

Otherwise:

Reserved, RES0.

UNKNOWN, bits [59:56]

From ARMv8.5:

Reserved, UNKNOWN.

Otherwise:

Reserved, RES0.

Bits [55:52]

Reserved, RES0.

UNKNOWN, bits [51:48]

From ARMv8.4:

Reserved, UNKNOWN.

Otherwise:

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMU, bits [47:44]

From ARMv8.4:

Activity Monitors Extension. Defined values are:

`0b0000` Activity Monitors Extension is not implemented.

`0b0001` Activity Monitors Extension version 1 is implemented.

All other values are reserved.

AMUv1 on page A2-93 implements the functionality identified by the value `0b0001`.

In Armv8.0, Armv8.1, Armv8.2, and Armv8.3, the only permitted value is `0b0000`.

From Armv8.4, the permitted values are `0b0000` and `0b0001`.

Otherwise:

Reserved, RES0.

UNKNOWN, bits [43:40]

From ARMv8.2:

Reserved, UNKNOWN.

Otherwise:

Reserved, RES0.

SEL2, bits [39:36]

From ARMv8.4:

Secure EL2. Defined values are:

`0b0000` Secure EL2 is not implemented.

`0b0001` Secure EL2 is implemented.

All other values are reserved.

Otherwise:

Reserved, RES0.

SVE, bits [35:32]

From ARMv8.2:

Scalable Vector Extension. Defined values are:

`0b0000` SVE is not implemented.

`0b0001` SVE is implemented.

All other values are reserved.

Otherwise:

Reserved, RES0.

UNKNOWN, bits [31:28]

From Armv8.2:

Reserved, UNKNOWN.

Otherwise:

Reserved, RES0.

GIC, bits [27:24]

System register GIC interface support. Defined values are:

`0b0000` No System register interface to the GIC is supported.

`0b0001` System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.GIC.

AdvSIMD, bits [23:20]

Advanced SIMD. Defined values are:

`0b0000` Advanced SIMD is implemented, including support for the following SISD and SIMD operations:

- Integer byte, halfword, word and doubleword element operations.
- Single-precision and double-precision floating-point arithmetic.
- Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.

`0b0001` As for `0b0000`, and also includes support for half-precision floating-point arithmetic.

`0b1111` Advanced SIMD is not implemented.

All other values are reserved.

This field must have the same value as the FP field.

The permitted values are:

- `0b0000` in an implementation with Advanced SIMD support, that does not include the ARMv8.2-FP16 extension.
- `0b0001` in an implementation with Advanced SIMD support, that includes the ARMv8.2-FP16 extension.
- `0b1111` in an implementation without Advanced SIMD support.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.AdvSIMD.

FP, bits [19:16]

Floating-point. Defined values are:

`0b0000` Floating-point is implemented, and includes support for:

- Single-precision and double-precision floating-point types.
- Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.

`0b0001` As for `0b0000`, and also includes support for half-precision floating-point arithmetic.

`0b1111` Floating-point is not implemented.

All other values are reserved.

This field must have the same value as the AdvSIMD field.

The permitted values are:

- `0b0000` in an implementation with floating-point support, that does not include the ARMv8.2-FP16 extension.
- `0b0001` in an implementation with floating-point support, that includes the ARMv8.2-FP16 extension.
- `0b1111` in an implementation without floating-point support.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.FP.

EL3, bits [15:12]

AArch64 EL3 Exception level handling. Defined values are:

`0b0000` EL3 is not implemented or cannot be executed in AArch64 state.

`0b0001` EL3 can be executed in AArch64 state only.

`0b0010` EL3 can be executed in either AArch64 or AArch32 state.

When the value of EDAA32PFR.EL3 is non-zero, this field must be `0b0000`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL3.

EL2, bits [11:8]

AArch64 EL2 Exception level handling. Defined values are:

`0b0000` EL2 is not implemented or cannot be executed in AArch64 state.

`0b0001` EL2 can be executed in AArch64 state only.

`0b0010` EL2 can be executed in either AArch64 or AArch32 state.

When the value of EDAA32PFR.EL2 is non-zero, this field must be `0b0000`.

All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL2.

EL1, bits [7:4]

AArch64 EL1 Exception level handling. Defined values are:

`0b0000` EL1 can be executed in AArch32 state only.

`0b0001` EL1 can be executed in AArch64 state only.

`0b0010` EL1 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL1.

EL0, bits [3:0]

AArch64 EL0 Exception level handling. Defined values are:

`0b0000` EL0 can be executed in AArch32 state only.

`0b0001` EL0 can be executed in AArch64 state only.

`0b0010` EL0 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

In an Armv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of ID_AA64PFR0_EL1.EL0.

Accessing the EDPFR:

EDPFR[31:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	`0xD20`	EDPFR	31:0

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() accesses to EDPFR[31:0] are RO.
- Otherwise accesses to EDPFR[31:0] are IMPDEF.

EDPFR[63:32] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	`0xD24`	EDPFR	63:32

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() accesses to EDPFR[63:32] are RO.
- Otherwise accesses to EDPFR[63:32] are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.34 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether EDPIDR0 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

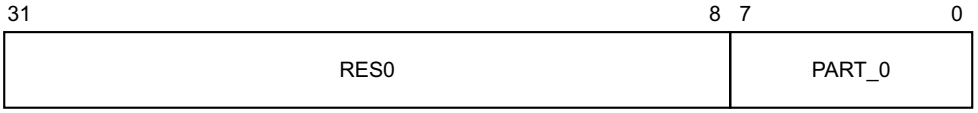
This register is required for CoreSight compliance.

Attributes

EDPIDR0 is a 32-bit register.

Field descriptions

The EDPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the EDPIDR0:

EDPIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFE0	EDPIDR0

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.35 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether EDPIDR1 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

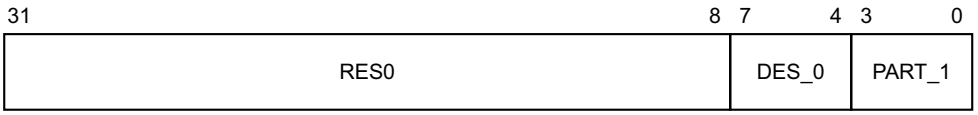
This register is required for CoreSight compliance.

Attributes

EDPIDR1 is a 32-bit register.

Field descriptions

The EDPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the EDPIDR1:

EDPIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFE4`	EDPIDR1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.36 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether EDPIDR2 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

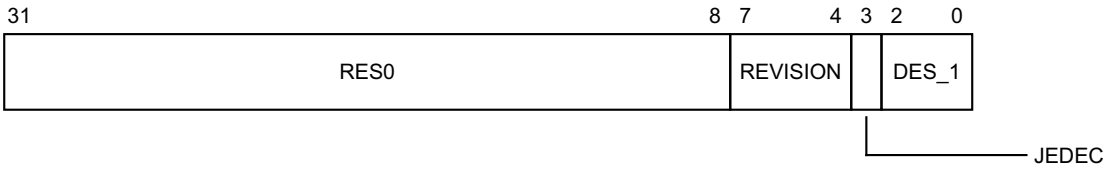
This register is required for CoreSight compliance.

Attributes

EDPIDR2 is a 32-bit register.

Field descriptions

The EDPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is `0b011`.

Accessing the EDPIDR2:

EDPIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFE8`	EDPIDR2

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.37 EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether EDPIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

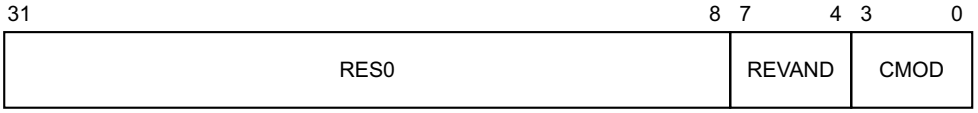
This register is required for CoreSight compliance.

Attributes

EDPIDR3 is a 32-bit register.

Field descriptions

The EDPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the EDPIDR3:

EDPIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFEC	EDPIDR3

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.38 EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether EDPIDR4 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

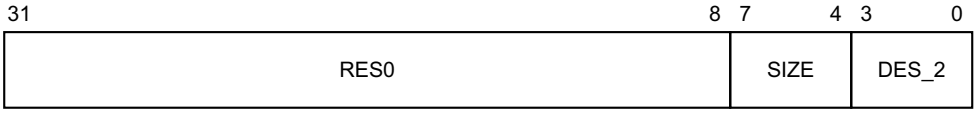
This register is required for CoreSight compliance.

Attributes

EDPIDR4 is a 32-bit register.

Field descriptions

The EDPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For Arm Limited, this field is `0b0100`.

Accessing the EDPIDR4:

EDPIDR4 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFD0`	EDPIDR4

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.39 EDPRCR, External Debug Power/Reset Control Register

The EDPRCR characteristics are:

Purpose

Controls the PE functionality related to powerup, reset, and powerdown.

Configurations

EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain.

For RW fields see the field description for a description of the behavior of the field on a reset that applies to its power domain. However:

- Fields that are in the Core power domain are not affected by a warm reset and are not affected by an External debug reset.
- Fields that are in the Debug power domain reset to their defined reset values on an External debug reset, and are not affected by a Warm reset and are not affected by a Cold reset.

If ARMv8.3-DoPD is implemented then all fields in this register are in the Core power domain.

CORENPDRQ is the only field that is mapped between the EDPRCR and DBGPRCR and DBGPRCR_EL1.

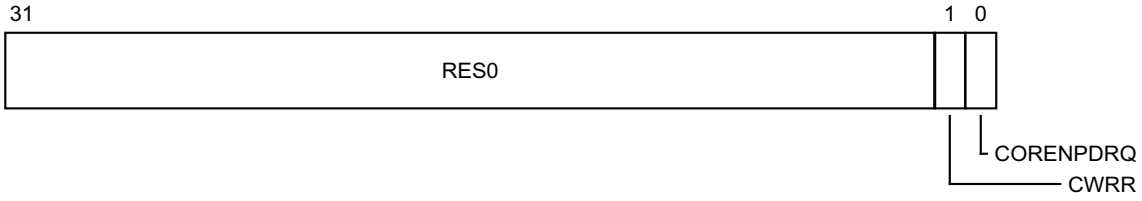
Attributes

EDPRCR is a 32-bit register.

Field descriptions

The EDPRCR bit assignments are:

When ARMv8.3-DoPD is implemented:



Bits [31:2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request. Write-only bit that reads as zero.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Arm deprecates use of this bit, and recommends that implementations ignore the request.

`0b0` No action.

`0b1` Request Warm reset.

This field is in the Core power domain

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The PE ignores writes to this bit if any of the following are true:

- ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Non-secure state.
- ExternalSecureInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Secure state.
- ExternalSecureInvasiveDebugEnabled() == FALSE and EL3 is implemented.

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

On a Warm reset, this field resets to `0`.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus(), or OSLockStatus() or SoftwareLockStatus(), access to this field is WI.
- Otherwise, access to this field is WO.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

`0b0` If the system responds to a powerdown request, it powers down Core power domain.

`0b1` If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

When this bit reads as UNKNOWN, the PE ignores writes to this bit.

This field is in the Core power domain, and permitted accesses to this field map to the DBGPRCR.CORENPDRQ and DBGPRCR_EL1.CORENPDRQ fields.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see *Core power domain power states* on page H6-6808.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

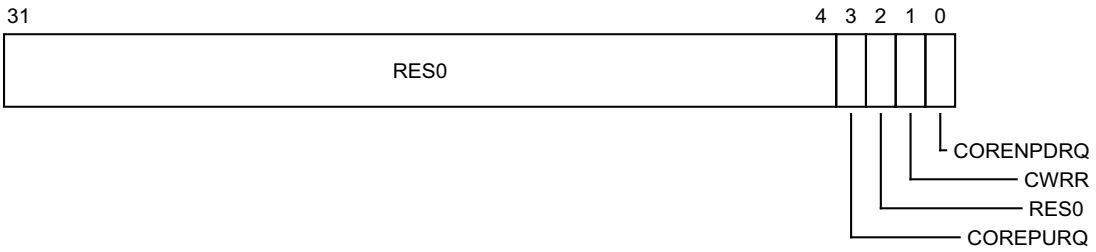
On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or OSLockStatus(), access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:



Bits [31:4]

Reserved, RES0.

COREPURQ bit [3]

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain, and that the power controller emulates powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

`0b0` Do not request power up of the Core power domain.

`0b1` Request power up of the Core power domain, and emulation of powerdown.

In an implementation that includes the recommended external debug interface, this bit drives the DBGPWRUPREQ signal.

This field is in the Debug power domain and can be read and written when the Core power domain is powered off.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a External debug reset, this field resets to `0`.

Accessing this field has the following behavior:

- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

Bit [2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request. Write-only bit that reads as zero.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Arm deprecates use of this bit, and recommends that implementations ignore the request.

`0b0` No action.

`0b1` Request Warm reset.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field is in the Core power domain

The PE ignores writes to this bit if any of the following are true:

- ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Non-secure state.
- ExternalSecureInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Secure state.
- ExternalSecureInvasiveDebugEnabled() == FALSE and EL3 is implemented.

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

On a Warm reset, this field resets to `0`.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus(), or OSLockStatus() or SoftwareLockStatus(), access to this field is WI.
- Otherwise, access to this field is WO.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

`0b0` If the system responds to a powerdown request, it powers down Core power domain.

`0b1` If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

When this bit reads as UNKNOWN, the PE ignores writes to this bit.

This field is in the Core power domain, and permitted accesses to this field map to the DBGPRCR.CORENPDRQ and DBGPRCR_EL1.CORENPDRQ fields.

In an implementation that includes the recommended external debug interface, this bit drives the DBGNOPWRDWN signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see *Core power domain power states* on page H6-6808.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or OSLockStatus(), access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

Accessing the EDPRCR:

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EDPRCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x310	EDPRCR

This interface is accessible as follows:

- When (ARMv8.3-DoPD is not implemented or IsCorePowered()) and SoftwareLockStatus() accesses to this register are RO.
- When (ARMv8.3-DoPD is not implemented or IsCorePowered()) and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.40 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

Purpose

Holds information about the reset and powerdown state of the PE.

Configurations

EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Some of the fields in the Core power domain are in the Cold reset domain and others are in the Warm reset domain. See the field descriptions for more information. However:

- Fields that are in the Cold reset domain are not affected by a warm reset and are not affected by an External debug reset.
- Fields in the Warm reset domain are also reset by a Cold reset but are not affected by an External debug reset.
- Fields in the Debug power domain are not affected by a Warm reset and are not affected by a Cold reset.

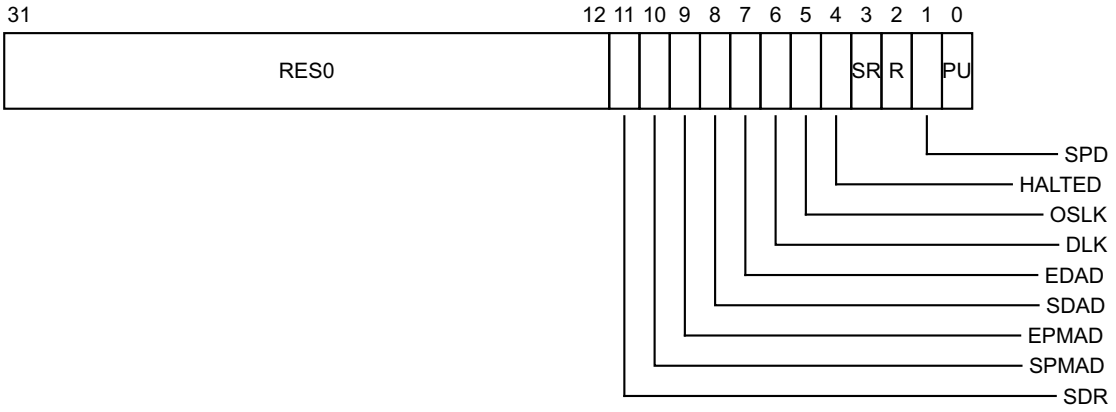
If ARMv8.3-DoPD is implemented then all fields in this register are in the Core power domain.

Attributes

EDPRSR is a 32-bit register.

Field descriptions

The EDPRSR bit assignments are:



Bits [31:12]

Reserved, RES0.

SDR, bit [11]

Sticky Debug Restart. Set to 1 when the PE exits Debug state.

Permitted values are:

`0b0` The PE has not restarted since EDPRSR was last read.

`0b1` The PE has restarted since EDPRSR was last read.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If a reset occurs when the PE is in Debug state, the PE exits Debug state. SDR is UNKNOWN on Warm reset, meaning a debugger must also use the SR bit to determine whether the PE has left Debug state.

If The Core power domain is powered up, then following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain and the Warm reset domain.

This field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC.

SPMAD, bit [10]

When ARMv8.4-Debug is implemented:

Sticky EPMAD error. Set to 1 if an external debug interface access to a Performance Monitors register returns an error because `AllowExternalPMUAccess()` == FALSE.

Permitted values are:

`0b0` No Non-secure external debug interface accesses to the external Performance Monitors registers have failed because `AllowExternalPMUAccess()` == FALSE for the access since EDPRSR was last read.

`0b1` At least one Non-secure external debug interface access to the external Performance Monitors register has failed and returned an error because `AllowExternalPMUAccess()` == FALSE for the access since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented, and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

On a Cold reset, this field resets to `0`.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC.

Otherwise:

Sticky EPMAD error.

`0b0` No external debug interface accesses to the Performance Monitors registers have failed because `AllowExternalPMUAccess()` == FALSE since EDPRSR was last read.

`0b1` At least one external debug interface access to the Performance Monitors registers has failed and returned an error because `AllowExternalPMUAccess()` == FALSE since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If ARMv8.0-DoubleLock is implemented, and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

On a Cold reset, this field resets to `0`.

Accessing this field has the following behavior:

- When !IsCorePowered(), or OSLockStatus(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC.

EPMAD, bit [9]

When ARMv8.4-Debug is implemented:

External Performance Monitors Access Disable status.

`0b0` External Non-secure Performance Monitors access enabled. `AllowExternalPMUAccess()` == TRUE for a Non-secure access.

`0b1` External Non-secure Performance Monitors access disabled. `AllowExternalPMUAccess()` == FALSE for a Non-secure access.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

Otherwise:

External Performance Monitors access disable status.

`0b0` External Performance Monitors access enabled. `AllowExternalPMUAccess()` == TRUE.

`0b1` External Performance Monitors access disabled. `AllowExternalPMUAccess()` == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or OSLockStatus(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

SDAD, bit [8]

When ARMv8.4-Debug is implemented:

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because `AllowExternalDebugAccess()` == FALSE.

`0b0` No Non-secure external debug interface accesses to the debug registers have failed because `AllowExternalDebugAccess()` == FALSE for the access since EDPRSR was last read.

`0b1` At least one Non-secure external debug interface access to the debug registers has failed and returned an error because `AllowExternalDebugAccess()` == FALSE for the access since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

On a Cold reset, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

Otherwise:

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because `AllowExternalDebugAccess()` == FALSE.

`0b0` No external debug interface accesses to the debug registers have failed because `AllowExternalDebugAccess()` == FALSE since EDPRSR was last read.

`0b1` At least one external debug interface access to the debug registers has failed and returned an error because `AllowExternalDebugAccess()` == FALSE since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This bit is UNKNOWN on reads if `OSLockStatus()` == TRUE and external debug writes to OSLAR_EL1 do not return an error when `AllowExternalDebugAccess()` == FALSE.

This field is in the Core power domain.

On a Cold reset, this field resets to `0`.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

EDAD, bit [7]

When ARMv8.4-Debug is implemented:

External Debug Access Disable status.

`0b0` External Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 enabled. `AllowExternalDebugAccess()` == TRUE for a Non-secure access.

`0b1` External Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 disabled. `AllowExternalDebugAccess()` == FALSE for a Non-secure access.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

When ARMv8.2-Debug is implemented:

External debug access disable status.

`0b0` External access to breakpoint registers, watchpoint registers, and OSLAR_EL1 enabled. `AllowExternalDebugAccess()` == TRUE.

`0b1` External access to breakpoint registers, watchpoint registers, and OSLAR_EL1 disabled. `AllowExternalDebugAccess()` == FALSE.

This bit is not valid and reads UNKNOWN if `OSLockStatus()` == TRUE and external debug writes to OSLAR_EL1 do not return an error when `AllowExternalDebugAccess()` == FALSE.

This field is in the Core power domain.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

Otherwise:

External Debug Access Disable status.

`0b0` External access to breakpoint registers, watchpoint registers, and OSLAR_EL1 enabled. `AllowExternalDebugAccess()` == TRUE.

`0b1` External access to breakpoint registers, watchpoint registers disabled. It is IMPLEMENTATION DEFINED whether accesses to OSLAR_EL1 are enabled or disabled. `AllowExternalDebugAccess()` == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), or DoubleLockStatus() or EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

DLK, bit [6]

When ARMv8.4-Debug is implemented:

This field is RES0.

When ARMv8.2-Debug is implemented and ARMv8.0-DoubleLock is implemented:

Double Lock.

From Armv8.2, this field is deprecated.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When IsCorePowered() and !DoubleLockStatus(), access to this field is RAZ.
- Otherwise, access to this field is UNKNOWN.

When ARMv8.0-DoubleLock is implemented:

Double Lock.

This field returns the result of the pseudocode function `DoubleLockStatus()`.

If the Core power domain is powered up and `DoubleLockStatus()` == TRUE, it is IMPLEMENTATION DEFINED whether:

- EDPRSR.PU reads as 1, EDPRSR.DLK reads as 1, and EDPRSR.SPD is UNKNOWN.
- EDPRSR.PU reads as 0, EDPRSR.DLK is UNKNOWN, and EDPRSR.SPD reads as 0.

This field is in the Core power domain.

`0b0` `DoubleLockStatus()` returns FALSE.

`0b1` `DoubleLockStatus()` returns TRUE and the Core power domain is powered up.

Accessing this field has the following behavior:

- When !IsCorePowered(), access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

Otherwise:

Reserved, RES0.

OSLK, bit [5]

OS Lock status bit.

A read of this bit returns the value of OSLSR_EL1.OSLK.

This field is in the Core power domain.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing this field has the following behavior:

- When !IsCorePowered(), DoubleLockStatus() and EDPRSR.R == 1, access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

HALTED, bit [4]

Halted status bit.

`0b0` PE is in Non-debug state.

`0b1` PE is in Debug state.

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered(), access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

SR, bit [3]

Sticky core Reset status bit.

Permitted values are:

`0b0` The non-debug logic of the PE is not in reset state and has not been reset since the last time EDPRSR was read.

`0b1` The non-debug logic of the PE is in reset state or has been reset since the last time EDPRSR was read.

If EDPRSR.PU reads as 1 and EDPRSR.R reads as 0, which means that the Core power domain is in a powerup state and that the non-debug logic of the PE is not in reset state, then following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain and the Warm reset domain.

This field resets to `1`.

Accessing this field has the following behavior:

- When !IsCorePowered() or DoubleLockStatus(), access to this field is UNKNOWN.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC.

R, bit [2]

PE reset status bit.

Permitted values are:

`0b0` The non-debug logic of the PE is not in reset state.

`0b1` The non-debug logic of the PE is in reset state.

If ARMv8.0-DoubleLock is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information see *EDPRSR.{DLK, R} and reset state* on page H6-6814

This field is in the Core power domain.

Accessing this field has the following behavior:

- When !IsCorePowered() or DoubleLockStatus(), access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

SPD, bit [1]

Sticky core Powerdown status bit.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If OS Double Lock is implemented and DoubleLockStatus() == TRUE then:

- If ARMv8.2-Debug is implemented, this bit reads as 0.
- If ARMv8.3-Debug is not implemented, this bit might read as 0 or 1.

For more information, see *EDPRSR.{DLK, SPD, PU} and the Core power domain* on page H6-6813.

`0b0` If EDPRSR.PU is 0, it is not known whether the state of the debug registers in the Core power domain is lost.

If EDPRSR.PU is 1, the state of the debug registers in the Core power domain has not been lost.

`0b1` The state of the debug registers in the Core power domain has been lost.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE this bit clears to 0.
- If ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

When the Core power domain is in either retention or powerdown state, the value of EDPRSR.SPD is IMPLEMENTATION DEFINED. For more information, see *EDPRSR.SPD when the Core domain is in either retention or powerdown state* on page H6-6814.

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see *EDPRSR.{DLK, SPD, PU} and the Core power domain* on page H6-6813.

This field is in the Core power domain and the Cold reset domain.

On a Cold reset, this field resets to `1`.

Accessing this field has the following behavior:

- When !IsCorePowered(), access to this field is RAZ.
- When IsCorePowered() and DoubleLockStatus(), access to this field is UNKNOWN.
- Otherwise, access to this field is RO.

PU, bit [0]

When ARMv8.3-DoPD is implemented:

Core Powerup status bit.

Access to this field is RAO.

When ARMv8.2-Debug is implemented:

Core Powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

`0b0` Either the Core power domain is in a low-power or powerdown state, or ARMv8.0-DoubleLock is implemented and `DoubleLockStatus()` == TRUE, meaning the debug registers in the Core power domain cannot be accessed.

`0b1` The Core power domain is in a powerup state, and either ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, meaning the debug registers in the Core power domain can be accessed.

If ARMv8.0-DoubleLock is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information see *EDPRSR.{DLK, R} and reset state* on page H6-6814

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see *EDPRSR.{DLK, SPD, PU} and the Core power domain* on page H6-6813

Access to this field is RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Core Powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

When the Core power domain is powered-up and `DoubleLockStatus()` == TRUE, then the value of EDPRSR.PU is IMPLEMENTATION DEFINED. See the description of the DLK bit for more information.

Otherwise, permitted values are:

`0b0` Core power domain is in a low-power or powerdown state where the debug registers in the Core power domain cannot be accessed.

`0b1` Core power domain is in a powerup state where the debug registers in the Core power domain can be accessed.

If ARMv8.0-DoubleLock is implemented, the Core power domain is powered up, and `DoubleLockStatus()` == TRUE, it is IMPLEMENTATION DEFINED whether this bit reads as 0 or 1.

If ARMv8.0-DoubleLock is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information see *EDPRSR.{DLK, R} and reset state* on page H6-6814

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see *EDPRSR.{DLK, SPD, PU} and the Core power domain* on page H6-6813

Access to this field is RO.

Accessing the EDPRSR:

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

If the Core power domain is powered up (EDPRSR.PU == 1), then following a read of EDPRSR:

- If ARMv8.0-DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, then:
  - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
  - EDPRSR.SR is cleared to 0 if the non-debug logic of the PE is not in reset state (EDPRSR.R == 0).
- Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

If the Core power domain is powered down (EDPRSR.PU == 0), then:

- EDPRSR.{SDR, SPMAD, SDAD, SR} are all UNKNOWN, and are either reset or restored on being powered up.
- EDPRSR.SPD is not cleared following a read of EDPRSR. See the SPD bit description for more information.

The clearing of bits is an indirect write to EDPRSR.

EDPRSR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0x314`	EDPRSR

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.41 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in EDSCR.

Configurations

EDRCR is in the Core power domain.

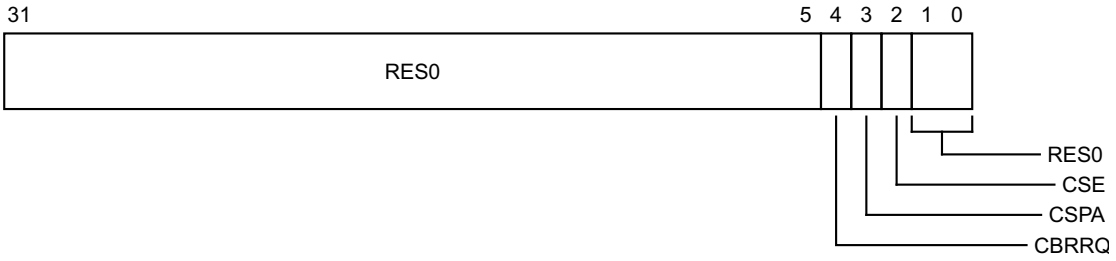
There are no configuration notes.

Attributes

EDRCR is a 32-bit register.

Field descriptions

The EDRCR bit assignments are:



Bits [31:5]

Reserved, RES0.

CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

`0b0` No action.

`0b1` Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the EDSCR.PipeAdv bit to 0. The actions on writing to this bit are:

`0b0` No action.

`0b1` Clear the EDSCR.PipeAdv bit to 0.

CSE, bit [2]

Clear Sticky Error. Used to clear the EDSCR cumulative error bits to 0. The actions on writing to this bit are:

`0b0` No action.

`0b1` Clear the EDSCR.{TXU, RXO, ERR} bits, and, if the PE is in Debug state, the EDSCR.ITO bit, to 0.

Bits [1:0]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the EDRCR:

EDRCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x090	EDRCR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are WI.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are WO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.42 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

Purpose

Main control register for the debug implementation.

Configurations

External register EDSCR[30:29] is architecturally mapped to AArch64 System register MDCCSR_EL0[30:29].

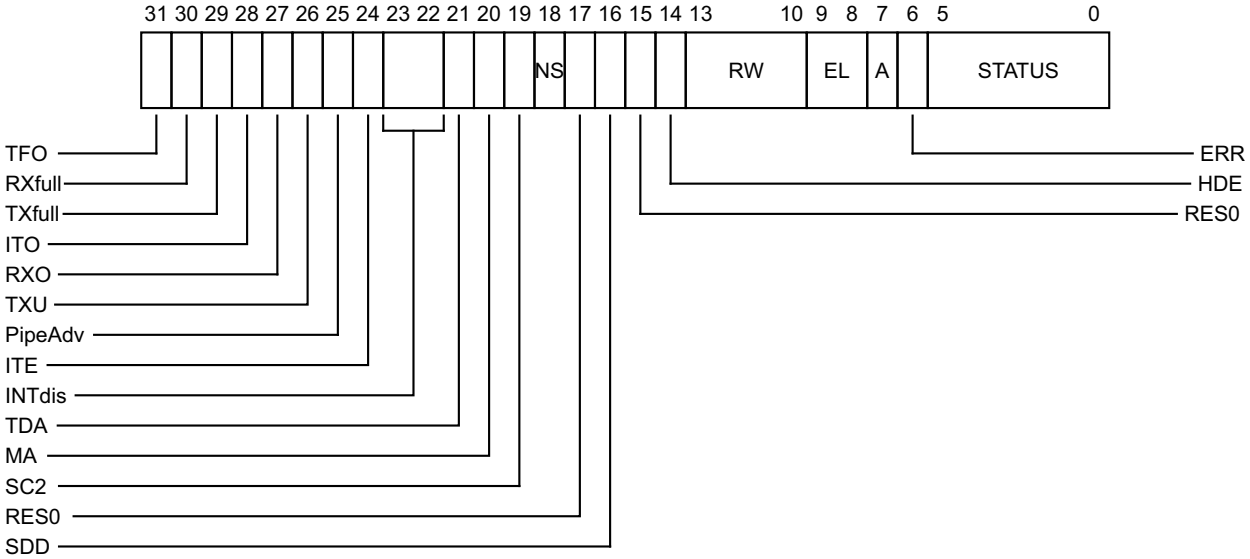
EDSCR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

EDSCR is a 32-bit register.

Field descriptions

The EDSCR bit assignments are:



TFO, bit [31]

When ARMv8.4-Trace is implemented:

Trace Filter Override. Overrides the Trace Filter controls allowing the external debugger to trace any visible Exception level.

`0b0` Trace Filter controls are not affected.

`0b1` Trace Filter controls in TRFCR_EL1, TRFCR_EL2, TRFCR, and HTRFCR are ignored.

When OSLSR_EL1.OSLK == 1, this bit can be indirectly read and written through the MDSCR_EL1 and DBGDSCRext System registers.

This bit is ignored by the PE when ExternalSecureNoninvasiveDebugEnabled() == FALSE and the Effective value of MDCR_EL3.STE == 1.

On a Cold reset, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

RXfull, bit [30]

DTRRX full. This bit is RO.

On a Cold reset, this field resets to `0`.

TXfull, bit [29]

DTRTX full. This bit is RO.

On a Cold reset, this field resets to `0`.

ITO, bit [28]

ITR overrun. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. ITO is set to 0 on entry to Debug state.

RXO, bit [27]

DTRRX overrun. This bit is RO.

On a Cold reset, this field resets to `0`.

TXU, bit [26]

DTRTX underrun. This bit is RO.

On a Cold reset, this field resets to `0`.

PipeAdv, bit [25]

Pipeline advance. This bit is RO. Set to 1 every time the PE pipeline retires one or more instructions. Cleared to 0 by a write to EDRCR.CSPA.

The architecture does not define precisely when this bit is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing.

ITE, bit [24]

ITR empty. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. It is always valid in Debug state.

INTdis, bits [23:22]

When ARMv8.4-Debug is implemented:

Interrupt disable. Disables taking interrupts in Non-Debug state.

`0b0` Masking of interrupts is controlled by PSTATE and interrupt routing controls.

`0b1` If ExternalSecureInvasiveDebugEnabled() == TRUE, then all interrupts, including virtual and SError interrupts, are masked.

If ExternalSecureInvasiveDebugEnabled() == FALSE, then all interrupts targetting Non-secure state are masked.

When OSLSR_EL1.OSLK == 1, this field can be indirectly read and written through the MDSCR_EL1 and DBGDSCRext System registers.

This field is ignored by the PE and treated as zero when ExternalDebugEnabled() == FALSE.

On a Cold reset, this field resets to `0`.

Otherwise:

Interrupt disable.

When OSLSR_EL1.OSLK == 1, this field can be indirectly read and written through the MDSCR_EL1 and DBGDSCRext System registers.

`0b00` Do not disable interrupts.

`0b01` Disable interrupts taken to Non-secure EL1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b10` Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If ExternalSecureInvasiveDebugEnabled() == TRUE, also disable interrupts taken to Secure EL1.

`0b11` Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If ExternalSecureInvasiveDebugEnabled() == TRUE, also disable all other interrupts.

On a Cold reset, this field resets to `0`.

TDA, bit [21]

Traps accesses to the following debug System registers:

- AArch64: DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, DBGWVR<n>_EL1.
- AArch32: DBGBCR<n>, DBGBVR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>.

The possible values of this field are:

`0b0` Accesses to debug System registers do not generate a Software Access Debug event.

`0b1` Accesses to debug System registers generate a Software Access Debug event, if OSLSR_EL1.OSLK is 0 and if halting is allowed.

On a Cold reset, this field resets to `0`.

MA, bit [20]

Memory access mode. Controls the use of memory-access mode for accessing ITR and the DCC. This bit is ignored if in Non-debug state and set to zero on entry to Debug state.

Possible values of this field are:

`0b0` Normal access mode.

`0b1` Memory access mode.

On a Cold reset, this field resets to `0`.

SC2, bit [19]

When ARMv8.0-PCSample is implemented, ARMv8.1-VHE is implemented and ARMv8.2-PCSample is not implemented:

Sample CONTEXTIDR_EL2. Controls whether the PC Sample-based Profiling Extension samples CONTEXTIDR_EL2 or VTTBR_EL2.VMID.

`0b0` Sample VTTBR_EL2.VMID.

`0b1` Sample CONTEXTIDR_EL2.

On a Cold reset, this field resets to `0`.

Otherwise:

Reserved, RES0.

NS, bit [18]

Non-secure status. Read-only. When in Debug state, gives the current Security state:

`0b0` Secure state, IsSecure() == TRUE.

`0b1` Non-secure state, IsSecure() == FALSE.

In Non-debug state, this bit is UNKNOWN.

Bit [17]

Reserved, RES0.

SDD, bit [16]

Secure debug disabled. This bit is RO.

On entry to Debug state:

- If entering in Secure state, SDD is set to 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If entering in Non-secure state, SDD is set to the inverse of ExternalSecureInvasiveDebugEnabled().

In Debug state, the value of the SDD bit does not change, even if ExternalSecureInvasiveDebugEnabled() changes.

In Non-debug state:

- SDD returns the inverse of ExternalSecureInvasiveDebugEnabled(). If the authentication signals that control ExternalSecureInvasiveDebugEnabled() change, a context synchronization event is required to guarantee their effect.
- This bit is unaffected by the Security state of the PE.

If EL3 is not implemented and the implementation is Non-secure, this bit is RES1.

Bit [15]

Reserved, RES0.

HDE, bit [14]

Halting debug enable. The possible values of this field are:

`0b0` Halting disabled for Breakpoint, Watchpoint and Halt Instruction debug events.

`0b1` Halting enabled for Breakpoint, Watchpoint and Halt Instruction debug events.

On a Cold reset, this field resets to `0`.

RW, bits [13:10]

Exception level Execution state status. Read-only. In Debug state, each bit gives the current Execution state of each Exception level:

`0b1111` All Exception levels are using AArch64 or the PE is in Non-debug state.

`0b1110` The PE is in Debug state. EL0 is using AArch32. All other Exception levels are using AArch64. Only permitted if the PE is executing at EL0.

`0b110x` The PE is in Debug state. EL0 and EL1 are using AArch32. EL2 and EL3 are using AArch64. Only permitted if EL2 is implemented and enabled in the current Security state.

`0b10xx` The PE is in Debug state. EL0, EL1, and, if implemented in the current Security state, EL2 are using AArch32. EL3 is using AArch64. Only permitted if EL3 is implemented.

`0b0xxx` The PE is in Debug state. All Exception levels are using AArch32.

In Non-debug state, this field is RAO.

EL, bits [9:8]

Exception level. Read-only. In Debug state, this gives the current EL of the PE.

In Non-debug state, this field is RAZ.

A, bit [7]

SError interrupt pending. Read-only. In Debug state, indicates whether an SError interrupt is pending:

- If HCR_EL2.{AMO, TGE} = {1, 0}, EL2 is enabled in the current Security state, and the PE is executing at EL0 or EL1, a virtual SError interrupt.
- Otherwise, a physical SError interrupt.

`0b0` No SError interrupt pending.

`0b1` SError interrupt pending.

A debugger can read EDSCR to check whether an SError interrupt is pending without having to execute further instructions. A pending SError might indicate data from target memory is corrupted.

UNKNOWN in Non-debug state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ERR, bit [6]

Cumulative error flag. This field is RO. It is set to 1 following exceptions in Debug state and on any signaled overrun or underrun on the DTR or EDITR.

On a Cold reset, this field resets to `0`.

STATUS, bits [5:0]

Debug status flags. This field is RO.

The possible values of this field are:

`0b000001` PE is restarting, exiting Debug state.

`0b000010` PE is in Non-debug state.

`0b000111` Breakpoint.

`0b010011` External debug request.

`0b011011` Halting step, normal.

`0b011111` Halting step, exclusive.

`0b100011` OS Unlock Catch.

`0b100111` Reset Catch.

`0b101011` Watchpoint.

`0b101111` HLT instruction.

`0b110011` Software access to debug register.

`0b110111` Exception Catch.

`0b111011` Halting step, no syndrome.

All other values of STATUS are reserved.

Accessing the EDSCR:

EDSCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0x088`	EDSCR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.43 EDVIDSR, External Debug Virtual Context Sample Register

The EDVIDSR characteristics are:

Purpose

Contains sampled values captured on reading EDPCSR[31:0].

Configurations

EDVIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented in the external debug registers space.

When the PC Sample-based Profiling Extension is implemented in the external debug registers space, if EL2 is not implemented and EL3 is not implemented, it is IMPLEMENTATION DEFINED whether EDVIDSR is implemented.

Note

ARMv8.2-PCSample implements the PC Sample-based Profiling Extension in the Performance Monitors registers space.

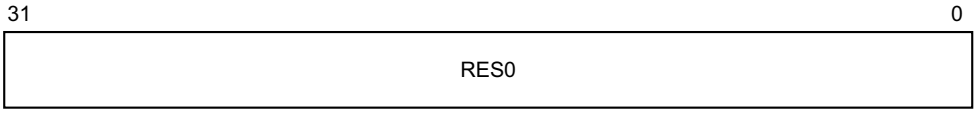
Attributes

If ARMv8.1-VHE is implemented, the format of this register differs depending on the value of EDSCR.SC2.

Field descriptions

The EDVIDSR bit assignments are:

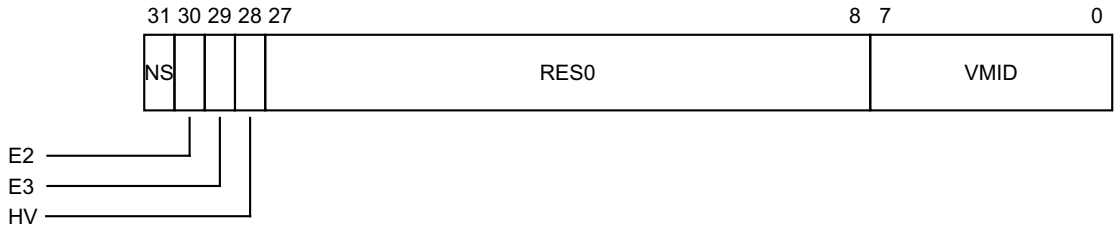
When ARMv8.2-PCSample is implemented:



Bits [31:0]

Reserved, RES0.

When ARMv8.1-VHE is not implemented:



NS, bit [31]

Non-secure state sample. Indicates the Security state associated with the most recent EDPCSR sample.

If EL3 is not implemented, this bit indicates the Effective value of SCR.NS.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E2, bit [30]

Exception level 2 status sample. Indicates whether the most recent EDPCSR sample was associated with EL2.

If EL2 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E3, bit [29]

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample was associated with EL3 using AArch64.

If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo (EDPCSR[31:0]) was read, this bit is 0.

If EL3 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HV, bit [28]

EDPCSRhi (EDPCSR[63:32]) valid. Indicates whether bits [63:32] of the most recent EDPCSR sample might be nonzero:

`0b0` Bits[63:32] of the most recent EDPCSR sample are zero.

`0b1` Bits[63:32] of the most recent EDPCSR sample might be nonzero.

An EDVIDSR.HV value of 1 does not mean that the value of EDPCSRhi is nonzero.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [27:8]

Reserved, RES0.

VMID, bits [7:0]

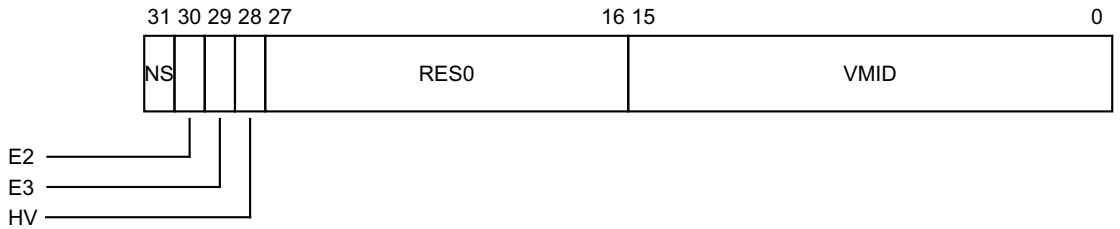
VMID sample. The VMID associated with the most recent EDPCSRlo (EDPCSR[31:0]) sample.

If EL2 is using AArch64 and the value of EDVIDSR.NS is 0 or the value of EDVIDSR.E2 is 1 this field is RES0.

If EL2 is not implemented, then this field is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 0:



This format applies in all Armv8.0 implementations.

NS, bit [31]

Non-secure state sample. Indicates the Security state associated with the most recent EDPCSR sample.

If EL3 is not implemented, this bit indicates the Effective value of SCR.NS.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2, bit [30]

Exception level 2 status sample. Indicates whether the most recent EDPCSR sample was associated with EL2.

If EL2 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

E3, bit [29]

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample was associated with EL3 using AArch64.

If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo (EDPCSR[31:0]) was read, this bit is 0.

If EL3 is not implemented, this bit is RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

HV, bit [28]

EDPCSRhi (EDPCSR[63:32]) valid. Indicates whether bits [63:32] of the most recent EDPCSR sample might be nonzero:

`0b0` Bits[63:32] of the most recent EDPCSR sample are zero.

`0b1` Bits[63:32] of the most recent EDPCSR sample might be nonzero.

An EDVIDSR.HV value of 1 does not mean that the value of EDPCSRhi is nonzero. An EDVIDSR.HV value of 0 is a hint that EDPCSRhi (EDPCSR[63:32]) does not need to be read.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [27:16]

Reserved, RES0.

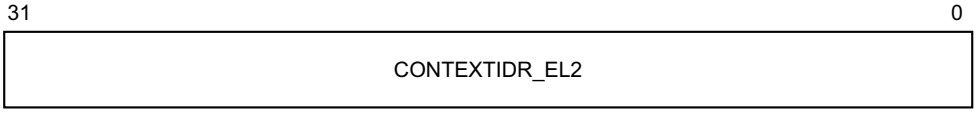
VMID, bits [15:0]

VMID sample. The VMID associated with the most recent EDPCSRlo (EDPCSR[31:0]) sample.

- If EL2 is using AArch64 and the value of EDVIDSR.NS is 0 or the value of EDVIDSR.E2 is 1 this field is RES0.
- If EL2 is not implemented, this field is RES0.
- If EL2 is implemented and is using AArch64, the VMID is held in VTTBR_EL2.VMID.
- If EL2 is implemented and is using AArch32, the VMID is held in VTTBR.VMID.
- If 16-bit VMIDs are not supported, EDVIDSR.VMID[15:8] is RES0.
- If 16-bit VMIDs are supported, but VTTBRx.VMID[15:8] are not used, EDVIDSR.VMID[15:8] is set to 0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 1:



CONTEXTIDR_EL2, bits [31:0]

Context ID.

- If EL2 is using AArch64 and if the value of EDPCSR.NS is 0, the value of CONTEXTIDR_EL2 as associated with the most recent EDPCSR sample.
- If the value of EDPCSR.NS is 0, then this field is set to an UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If neither of the above conditions are true, this field is set to an UNKNOWN value.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the EDVIDSR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824

EDVIDSR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x0A8	EDVIDSR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.44 EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

Purpose

Returns the virtual data address being accessed when a Watchpoint Debug Event was triggered.

Configurations

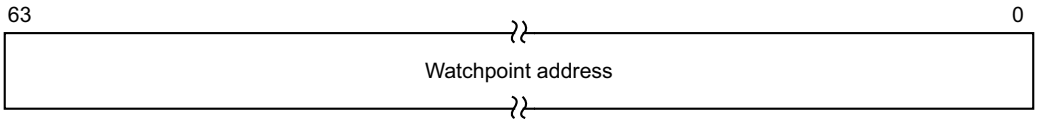
EDWAR is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

EDWAR is a 64-bit register.

Field descriptions

The EDWAR bit assignments are:



Bits [63:0]

Watchpoint address. The data virtual address being accessed when a Watchpoint Debug Event was triggered and caused entry to Debug state. This address must be within a naturally-aligned block of memory of power-of-two size no larger than the DC ZVA block size.

The value of this register is UNKNOWN if the PE is in Non-debug state, or if Debug state was entered other than for a Watchpoint debug event.

The value of EDWAR[63:32] is UNKNOWN if Debug state was entered for a Watchpoint debug event taken from AArch32 state.

The EDWAR is subject to the same alignment rules as the reporting of a watchpointed address in the FAR. See *Determining the memory location that caused a Watchpoint exception* on page D2-2439

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the EDWAR:

EDWAR[31:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	0x030	EDWAR	31:0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to EDWAR[31:0] are RO.
- Otherwise accesses to EDWAR[31:0] generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EDWAR[63:32] can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	0x034	EDWAR	63:32

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to EDWAR[63:32] are RO.
- Otherwise accesses to EDWAR[63:32] generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.45 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

Configurations

External register MIDR_EL1[31:0] is architecturally mapped to AArch64 System register MIDR_EL1[31:0].

External register MIDR_EL1[31:0] is architecturally mapped to AArch32 System register MIDR[31:0].

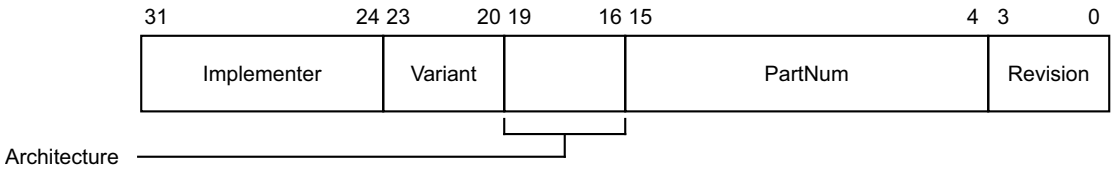
It is IMPLEMENTATION DEFINED whether MIDR_EL1 is implemented in the Core power domain or in the Debug power domain.

Attributes

MIDR_EL1 is a 32-bit register.

Field descriptions

The MIDR_EL1 bit assignments are:



Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm. Assigned codes include the following:

Hex representation	Implementer
0x00	Reserved for software use
0xC0	Ampere Computing
0x41	Arm Limited
0x42	Broadcom Corporation
0x43	Cavium Inc.
0x44	Digital Equipment Corporation
0x49	Infineon Technologies AG
0x4D	Motorola or Freescale Semiconductor Inc.
0x4E	NVIDIA Corporation
0x50	Applied Micro Circuits Corporation

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Hex representation	Implementer
0x51	Qualcomm Inc.
0x56	Marvell International Ltd.
0x69	Intel Corporation

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

0b0001 Armv4.

0b0010 Armv4T.

0b0011 Armv5 (obsolete).

0b0100 Armv5T.

0b0101 Armv5TE.

0b0110 Armv5TEJ.

0b0111 Armv6.

0b1111 Architectural features are individually identified in the ID_* registers, see Table K14-9 on page K14-7832

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1:

MIDR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xD00	MIDR_EL1

This interface is accessible as follows:

- When IsCorePowered() and !DoubleLockStatus() accesses to this register are RO.
- Otherwise accesses to this register are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.2.46 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS lock.

Configurations

External register OSLAR_EL1[31:0] is architecturally mapped to AArch64 System register OSLAR_EL1[31:0].

External register OSLAR_EL1[31:0] is architecturally mapped to AArch32 System register DBGOSLAR[31:0].

OSLAR_EL1 is in the Core power domain.

If ARMv8.2-Debug is not implemented, it is IMPLEMENTATION DEFINED whether external debug accesses to OSLAR_EL1 are ignored and return an error when AllowExternalDebugAccess() returns FALSE for the access.

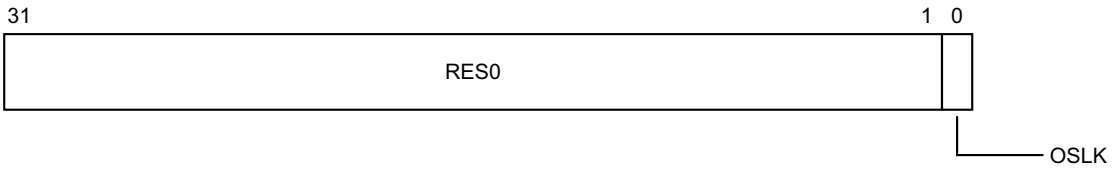
If ARMv8.2-Debug is implemented, external debug accesses to OSLAR_EL1 are ignored and return an error when AllowExternalDebugAccess() returns FALSE for the access.

Attributes

OSLAR_EL1 is a 32-bit register.

Field descriptions

The OSLAR_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.

Use EDPRSR.OSLK to check the current status of the lock.

Accessing the OSLAR_EL1:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

OSLAR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x300	OSLAR_EL1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() accesses to this register are WI.
- When IsCorePowered(), !DoubleLockStatus(), AllowExternalDebugAccess() and !SoftwareLockStatus() accesses to this register are WO.
- When IsCorePowered(), !DoubleLockStatus(), !AllowExternalDebugAccess() and ARMv8.2-Debug is not implemented accesses to this register are IMPDEF.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3 Cross-Trigger Interface registers

This section lists the Cross-Trigger Interface registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.1 ASICCTL, CTI External Multiplexer Control register

The ASICCTL characteristics are:

Purpose

Can be used to provide IMPLEMENTATION DEFINED controls for the CTI. For example, the register might be used to control multiplexors for additional IMPLEMENTATION DEFINED triggers. The IMPLEMENTATION DEFINED controls provided by this register might modify the architecturally defined behavior of the CTI.

Note

The architecturally-defined triggers must not be multiplexed.

Configurations

It is IMPLEMENTATION DEFINED whether ASICCTL is implemented in the Core power domain or in the Debug power domain.

If it is implemented in the Core power domain then it is IMPLEMENTATION DEFINED whether it is in the Cold reset domain or the Warm reset domain.

This register must reset to a value that supports the architecturally-defined behavior of the CTI. Changing the value of the register from its reset value causes IMPLEMENTATION DEFINED behavior that might differ from the architecturally-defined behavior of the CTI.

Other than the requirements listed in this register description, all aspects of the reset behavior of the ASICCTL are IMPLEMENTATION DEFINED.

Attributes

ASICCTL is a 32-bit register.

Field descriptions

The ASICCTL bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ASICCTL:

ASICCTL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x144	ASICCTL

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess() and SoftwareLockStatus() accesses to this register are RO.
- Otherwise accesses to this register are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.2 CTIAPPCLEAR, CTI Application Trigger Clear register

The CTIAPPCLEAR characteristics are:

Purpose

Clears bits of the Application Trigger register.

Configurations

CTIAPPCLEAR is in the Debug power domain.

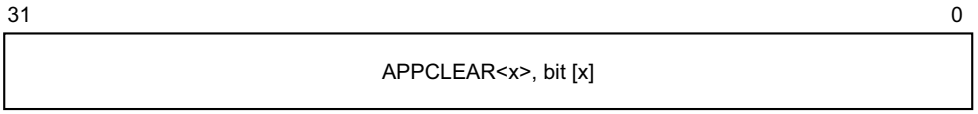
There are no configuration notes.

Attributes

CTIAPPCLEAR is a 32-bit register.

Field descriptions

The CTIAPPCLEAR bit assignments are:



APPCLEAR<x>, bit [x], for x = 0 to 31

Application trigger <x> disable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

`0b0` No effect.

`0b1` Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

If the ECT does not support multicycle channel events, use of CTIAPPCLEAR is deprecated and the debugger must only use CTIAPPPULSE.

Accessing the CTIAPPCLEAR:

CTIAPPCLEAR can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x018`	CTIAPPCLEAR

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are WI.
- When !SoftwareLockStatus() accesses to this register are WO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.3 CTIAPPPULSE, CTI Application Pulse register

The CTIAPPPULSE characteristics are:

Purpose

Causes event pulses to be generated on ECT channels.

Configurations

CTIAPPPULSE is in the Debug power domain.

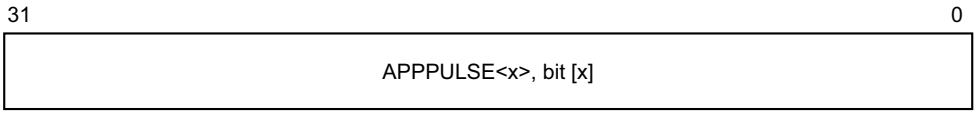
There are no configuration notes.

Attributes

CTIAPPPULSE is a 32-bit register.

Field descriptions

The CTIAPPPULSE bit assignments are:



APPPULSE<x>, bit [x], for x = 0 to 31

Generate event pulse on ECT channel <x>.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

`0b0` No effect.

`0b1` Channel <x> event pulse generated.

Note

- The CTIAPPPULSE operation does not affect the state of the Application Trigger register, CTIAPPTRIG. If the channel is active, either because of an earlier event or from the application trigger, then the value written to CTIAPPPULSE might have no effect.
- Multiple pulse events that occur close together might be merged into a single pulse event.

Accessing the CTIAPPPULSE:

It is CONSTRAINED UNPREDICTABLE whether a write to CTIAPPPULSE generates an event on a channel if CTICONTROL.GLBEN is 0.

CTIAPPPULSE can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x01C`	CTIAPPPULSE

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are WI.
- When !SoftwareLockStatus() accesses to this register are WO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.4 CTIAPPSET, CTI Application Trigger Set register

The CTIAPPSET characteristics are:

Purpose

Sets bits of the Application Trigger register.

Configurations

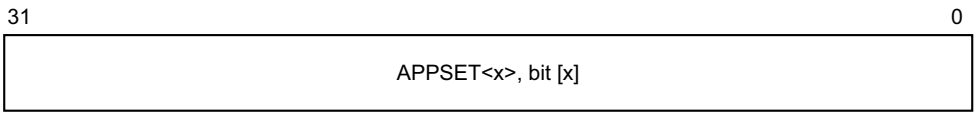
CTIAPPSET is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Attributes

CTIAPPSET is a 32-bit register.

Field descriptions

The CTIAPPSET bit assignments are:



APPSET<x>, bit [x], for x = 0 to 31

Application trigger <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0b0` Reading this means the application trigger is inactive. Writing this has no effect.

`0b1` Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPPTRIG to 1 and generates a channel event.

If the ECT does not support multicycle channel events, use of CTIAPPSET is deprecated and the debugger must only use CTIAPPPULSE.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing the CTIAPPSET:

CTIAPPSET can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x014`	CTIAPPSET

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.5 CTIAUTHSTATUS, CTI Authentication Status register

The CTIAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

Configurations

CTIAUTHSTATUS is in the Debug power domain.

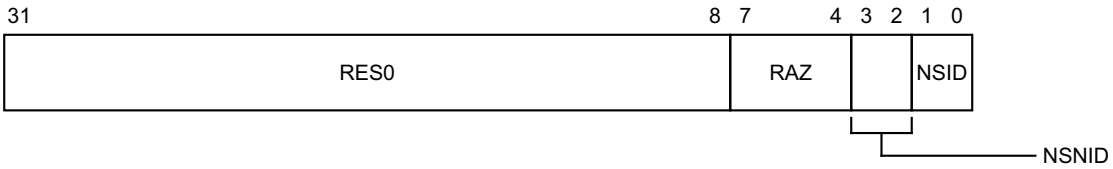
This register is OPTIONAL, and is required for CoreSight compliance.

Attributes

CTIAUTHSTATUS is a 32-bit register.

Field descriptions

The CTIAUTHSTATUS bit assignments are:



Bits [31:8]

Reserved, RES0.

Bits [7:4]

Reserved, RAZ.

NSNID, bits [3:2]

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SNID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSNID.

NSID, bits [1:0]

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSID.

Accessing the CTIAUTHSTATUS:

CTIAUTHSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFB8	CTIAUTHSTATUS

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.6 CTICHINSTATUS, CTI Channel In Status register

The CTICHINSTATUS characteristics are:

Purpose

Provides the raw status of the ECT channel inputs to the CTI.

Configurations

CTICHINSTATUS is in the Debug power domain.

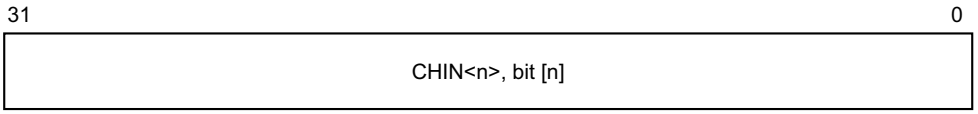
There are no configuration notes.

Attributes

CTICHINSTATUS is a 32-bit register.

Field descriptions

The CTICHINSTATUS bit assignments are:



CHIN<n>, bit [n], for n = 0 to 31

Input channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0b0` Input channel <n> is inactive.

`0b1` Input channel <n> is active.

If the ECT channels do not support multicycle events then it is IMPLEMENTATION DEFINED whether an input channel can be observed as active.

Accessing the CTICHINSTATUS:

CTICHINSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x138`	CTICHINSTATUS

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.7 CTICHOUTSTATUS, CTI Channel Out Status register

The CTICHOUTSTATUS characteristics are:

Purpose

Provides the status of the ECT channel outputs from the CTI.

Configurations

CTICHOUTSTATUS is in the Debug power domain.

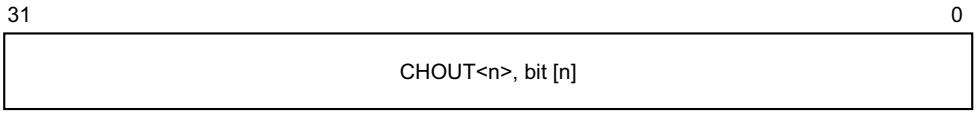
There are no configuration notes.

Attributes

CTICHOUTSTATUS is a 32-bit register.

Field descriptions

The CTICHOUTSTATUS bit assignments are:



CHOUT<n>, bit [n], for n = 0 to 31

Output channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0b0` Output channel <n> is inactive.

`0b1` Output channel <n> is active.

If the ECT channels do not support multicycle events then it is IMPLEMENTATION DEFINED whether an output channel can be observed as active.

Note

The value in CTICHOUTSTATUS is after gating by the channel gate. For more information, see CTIGATE.

Accessing the CTICHOUTSTATUS:

CTICHOUTSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x13C`	CTICHOUTSTATUS

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.8 CTICIDR0, CTI Component Identification Register 0

The CTICIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

CTICIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

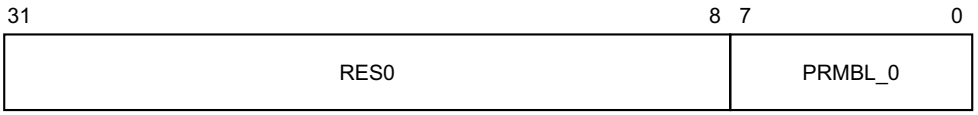
This register is required for CoreSight compliance.

Attributes

CTICIDR0 is a 32-bit register.

Field descriptions

The CTICIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the CTICIDR0:

CTICIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFF0`	CTICIDR0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.9 CTICIDR1, CTI Component Identification Register 1

The CTICIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

CTICIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

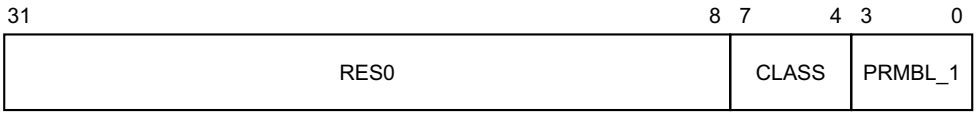
This register is required for CoreSight compliance.

Attributes

CTICIDR1 is a 32-bit register.

Field descriptions

The CTICIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the CTICIDR1:

CTICIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFF4`	CTICIDR1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.10 CTICIDR2, CTI Component Identification Register 2

The CTICIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

CTICIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

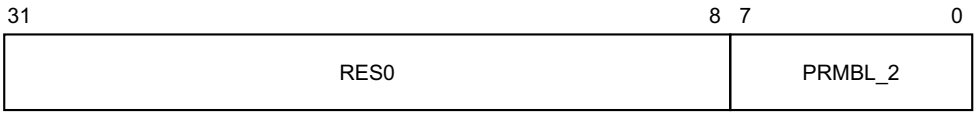
This register is required for CoreSight compliance.

Attributes

CTICIDR2 is a 32-bit register.

Field descriptions

The CTICIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the CTICIDR2:

CTICIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFF8`	CTICIDR2

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.11 CTICIDR3, CTI Component Identification Register 3

The CTICIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

CTICIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

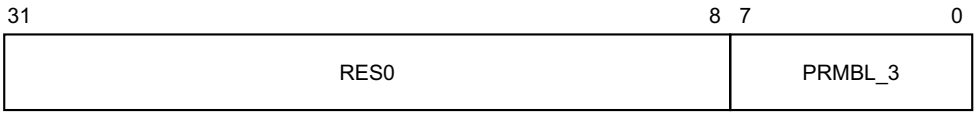
This register is required for CoreSight compliance.

Attributes

CTICIDR3 is a 32-bit register.

Field descriptions

The CTICIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the CTICIDR3:

CTICIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFFC`	CTICIDR3

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.12 CTICLAIMCLR, CTI Claim Tag Clear register

The CTICLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

Configurations

CTICLAIMCLR is in the Debug power domain.

This register is not affected by a Warm reset, and is not affected by a Cold reset.

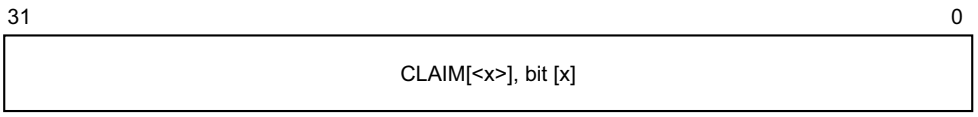
Implementation of this register is OPTIONAL.

Attributes

CTICLAIMCLR is a 32-bit register.

Field descriptions

The CTICLAIMCLR bit assignments are:



CLAIM[<x>], bit [x], for x = 0 to 31

CLAIM tag clear bit.

For values of x greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

For other values of x, reads return the value of CLAIM[x] and the behavior on writes is:

`0b0` No action.

`0b1` Indirectly clear CLAIM[x] to 0.

A single write to CTICLAIMCLR can clear multiple tags to 0.

Accessing the CTICLAIMCLR:

CTICLAIMCLR can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFA4`	CTICLAIMCLR

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.13 CTICLAIMSET, CTI Claim Tag Set register

The CTICLAIMSET characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

Configurations

CTICLAIMSET is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

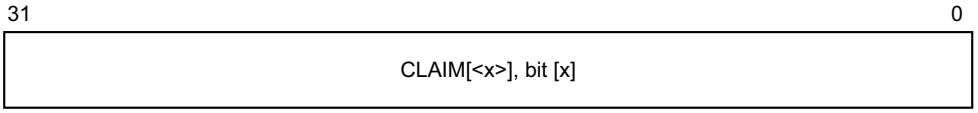
Implementation of this register is OPTIONAL.

Attributes

CTICLAIMSET is a 32-bit register.

Field descriptions

The CTICLAIMSET bit assignments are:



CLAIM[<x>], bit [x], for x = 0 to 31

CLAIM tag set bit.

For values of x greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

For other values of x, the bit is RAO and the behavior on writes is:

`0b0` No action.

`0b1` Indirectly set CLAIM[x] tag to 1.

A single write to CTICLAIMSET can set multiple tags to 1.

An External Debug reset clears the CLAIM tag bits to 0.

Accessing the CTICLAIMSET:

CTICLAIMSET can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFA0`	CTICLAIMSET

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.14 CTICONTROL, CTI Control register

The CTICONTROL characteristics are:

Purpose

Controls whether the CTI is enabled.

Configurations

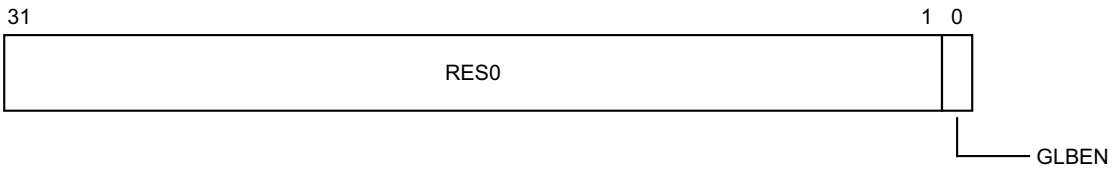
CTICONTROL is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Attributes

CTICONTROL is a 32-bit register.

Field descriptions

The CTICONTROL bit assignments are:



Bits [31:1]

Reserved, RES0.

GLBEN, bit [0]

Enables or disables the CTI mapping functions. Possible values of this field are:

`0b0` CTI mapping functions and application trigger disabled.

`0b1` CTI mapping functions and application trigger enabled.

When GLBEN is 0, the input channel to output trigger, input trigger to output channel, and application trigger functions are disabled and do not signal new events on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset.

If the ECT supports multicycle channel events any existing output channel events will be terminated.

On a External debug reset, this field resets to `0`.

Accessing the CTICONTROL:

CTICONTROL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x000`	CTICONTROL

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.15 CTIDEVAFF0, CTI Device Affinity register 0

The CTIDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

If the CTI is CTIv1, this register is OPTIONAL. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

In an Armv8.5 compliant implementation the CTI must be CTIv2.

If this register is implemented, then CTIDEVAFF1 must also be implemented. If the CTI of a PE does not implement the CTI Device Affinity registers, the CTI block of the external debug memory map must be located 64KB above the debug registers in the external debug interface.

Configurations

CTIDEVAFF0 is in the Debug power domain.

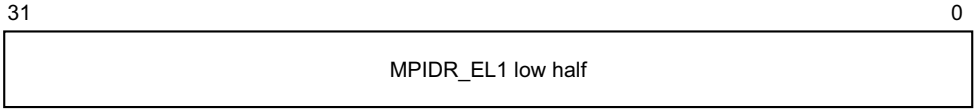
Implementation of this register is OPTIONAL.

Attributes

CTIDEVAFF0 is a 32-bit register.

Field descriptions

The CTIDEVAFF0 bit assignments are:



MPIDR_EL1 low half, bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF0:

CTIDEVAFF0 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFA8	CTIDEVAFF0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.16 CTIDEVAFF1, CTI Device Affinity register 1

The CTIDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

If the CTI is CTIv1, this register is OPTIONAL. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

In an Armv8.5 compliant implementation the CTI must be CTIv2.

If this register is implemented, then CTIDEVAFF0 must also be implemented. If the CTI of a PE does not implement the CTI Device Affinity registers, the CTI block of the external debug memory map must be located 64KB above the debug registers in the external debug interface.

Configurations

CTIDEVAFF1 is in the Debug power domain.

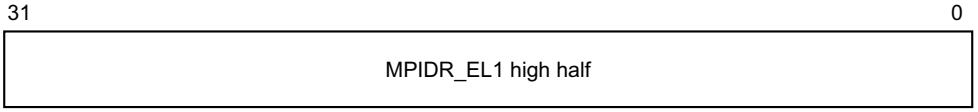
Implementation of this register is OPTIONAL.

Attributes

CTIDEVAFF1 is a 32-bit register.

Field descriptions

The CTIDEVAFF1 bit assignments are:



MPIDR_EL1 high half, bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF1:

CTIDEVAFF1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFAC	CTIDEVAFF1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.17 CTIDEVARCH, CTI Device Architecture register

The CTIDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the CTI component.

If the CTI is CTIv1, this register is OPTIONAL. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

In an Armv8.5 compliant implementation the CTI must be CTIv2.

If this register is not implemented, CTIDEVAFF0 and CTIDEVAFF1 are also not implemented.

Configurations

CTIDEVARCH is in the Debug power domain.

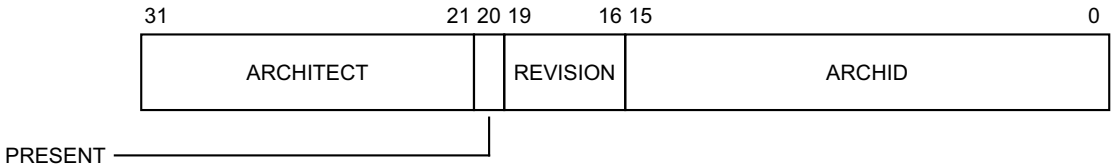
Implementation of this register is OPTIONAL.

Attributes

CTIDEVARCH is a 32-bit register.

Field descriptions

The CTIDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For CTI, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, `0x4`.

Bits [27:21] are the JEP106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in Armv8.

REVISION, bits [19:16]

Revision.

Defines the architecture revision of the component.

`0b0000` First revision.

`0b0001` **When ARMv8.3-DoPD is implemented** As `0b0000`, and also adds support for CTIDEVCTL.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an Armv8 debug component. For architectures defined by Arm this is further subdivided.

For CTI:

- Bits [15:12] are the architecture version, `0x1`.
- Bits [11:0] are the architecture part number, `0xA14`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This corresponds to CTI architecture version CTIv2.

Accessing the CTIDEVARCH:

CTIDEVARCH can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFBC	CTIDEVARCH

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.18 CTIDEVCTL, CTI Device Control register

The CTIDEVCTL characteristics are:

Purpose

Provides target-specific device controls

Configurations

CTIDEVCTL is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

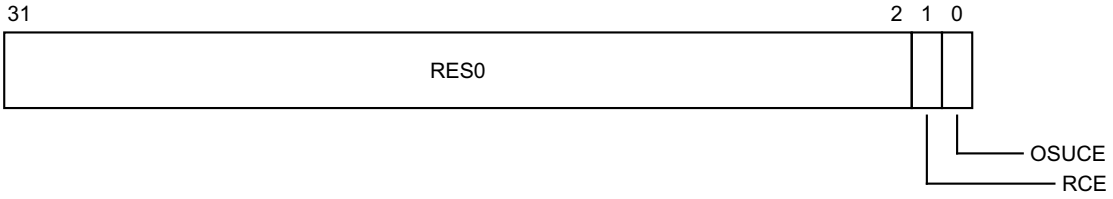
This register is present only when ARMv8.3-DoPD is implemented. Otherwise, direct accesses to CTIDEVCTL are RES0.

Attributes

CTIDEVCTL is a 32-bit register.

Field descriptions

The CTIDEVCTL bit assignments are:



Bits [31:2]

Reserved, RES0.

RCE, bit [1]

Reset Catch Enable.

`0b0` Reset Catch debug event disabled.

`0b1` Reset Catch debug event enabled.

On a External debug reset, this field resets to `0`.

OSUCE, bit [0]

OS Unlock Catch Enable

`0b0` OS Unlock Catch debug event disabled.

`0b1` OS Unlock Catch debug event enabled.

On a External debug reset, this field resets to `0`.

Accessing the CTIDEVCTL:

CTIDEVCTL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x150`	CTIDEVCTL

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.19 CTIDEVID, CTI Device ID register 0

The CTIDEVID characteristics are:

Purpose

Describes the CTI component to the debugger.

Configurations

CTIDEVID is in the Debug power domain.

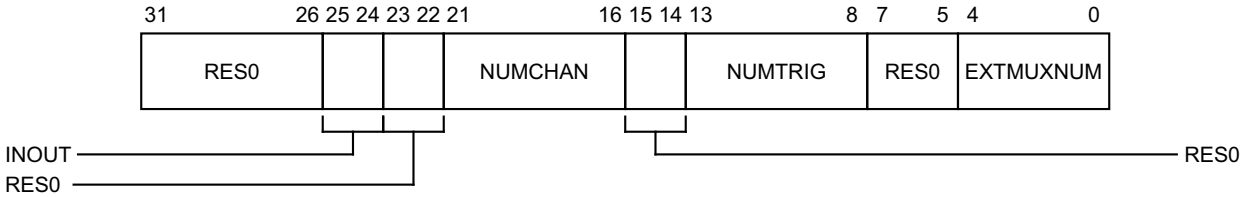
There are no configuration notes.

Attributes

CTIDEVID is a 32-bit register.

Field descriptions

The CTIDEVID bit assignments are:



Bits [31:26]

Reserved, RES0.

INOUT, bits [25:24]

Input/output options. Indicates presence of the input gate. If the CTM is not implemented or CTIv2 is not implemented, this field is RAZ.

`0b00` CTIGATE does not mask propagation of input events from external channels.

`0b01` CTIGATE masks propagation of input events from external channels.

All other values are reserved.

Bits [23:22]

Reserved, RES0.

NUMCHAN, bits [21:16]

Number of ECT channels implemented. IMPLEMENTATION DEFINED. For Armv8, valid values are:

`0b000011` 3 channels (0..2) implemented.

`0b000100` 4 channels (0..3) implemented.

`0b000101` 5 channels (0..4) implemented.

`0b000110` 6 channels (0..5) implemented.

and so on up to `0b100000`, 32 channels (0..31) implemented.

All other values are reserved.

Bits [15:14]

Reserved, RES0.

NUMTRIG, bits [13:8]

Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For Armv8, valid values are:

`0b000011` Up to 3 triggers (0..2) implemented.

`0b001000` Up to 8 triggers (0..7) implemented.

`0b001001` Up to 9 triggers (0..8) implemented.

`0b001010` Up to 10 triggers (0..9) implemented.

and so on up to `0b100000`, 32 triggers (0..31) implemented.

All other values are reserved. If the contains a Trace extension, this field must be at least `0b001000`. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.

Bits [7:5]

Reserved, RES0.

EXTMUXNUM, bits [4:0]

Number of multiplexors available on triggers. This value is used in conjunction with External Control register, ASICCTL.

Accessing the CTIDEVID:

CTIDEVID can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFC8`	CTIDEVID

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.20 CTIDEVID1, CTI Device ID register 1

The CTIDEVID1 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Configurations

CTIDEVID1 is in the Debug power domain.

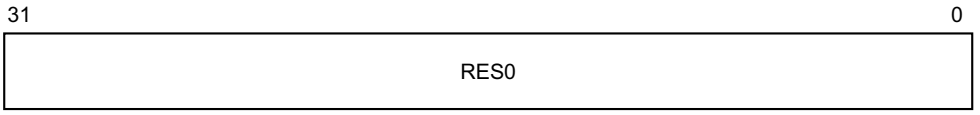
There are no configuration notes.

Attributes

CTIDEVID1 is a 32-bit register.

Field descriptions

The CTIDEVID1 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID1:

CTIDEVID1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFC4	CTIDEVID1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.21 CTIDEVID2, CTI Device ID register 2

The CTIDEVID2 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Configurations

CTIDEVID2 is in the Debug power domain.

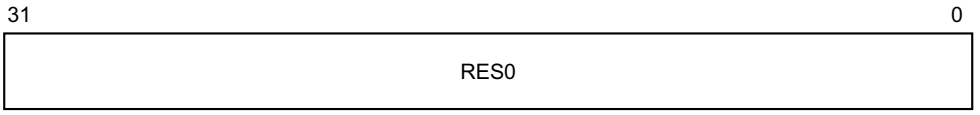
There are no configuration notes.

Attributes

CTIDEVID2 is a 32-bit register.

Field descriptions

The CTIDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID2:

CTIDEVID2 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFC0	CTIDEVID2

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.22 CTIDEVTYPE, CTI Device Type register

The CTIDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PEs cross-trigger interface.

Configurations

CTIDEVTYPE is in the Debug power domain.

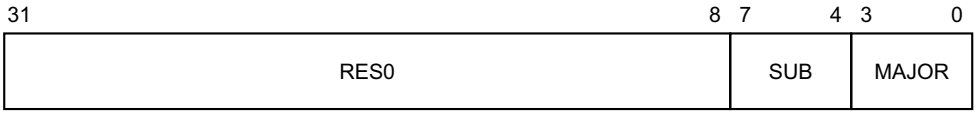
Implementation of this register is OPTIONAL.

Attributes

CTIDEVTYPE is a 32-bit register.

Field descriptions

The CTIDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as `0x4` to indicate this is a cross-trigger component.

Accessing the CTIDEVTYPE:

CTIDEVTYPE can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFCC`	CTIDEVTYPE

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.23 CTIGATE, CTI Channel Gate Enable register

The CTIGATE characteristics are:

Purpose

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

Configurations

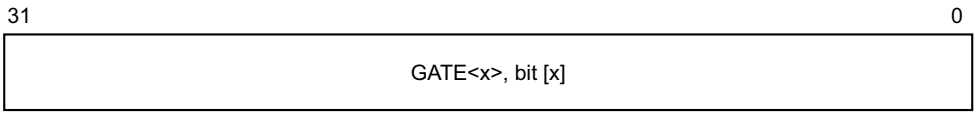
CTIGATE is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Attributes

CTIGATE is a 32-bit register.

Field descriptions

The CTIGATE bit assignments are:



GATE<x>, bit [x], for x = 0 to 31

Channel <x> gate enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0b0` Disable output and, if CTIDEVID.INOUT == `0b01`, input channel <x> propagation.

`0b1` Enable output and, if CTIDEVID.INOUT == `0b01`, input channel <x> propagation.

If GATE[x] is set to 0, no new events will be propagated to the ECT, and if the ECT supports multicycle channel events any existing output channel events will be terminated.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing the CTIGATE:

CTIGATE can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x140`	CTIGATE

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.24 CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31

The CTIINEN<n> characteristics are:

Purpose

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

Configurations

CTIINEN<n> is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

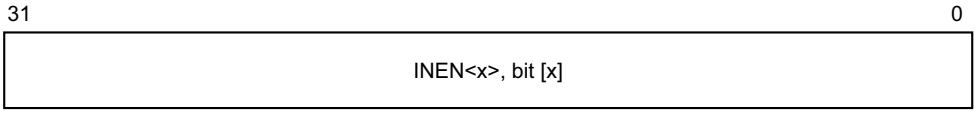
If input trigger n is not connected, the behavior of CTIINEN<n> is IMPLEMENTATION DEFINED.

Attributes

CTIINEN<n> is a 32-bit register.

Field descriptions

The CTIINEN<n> bit assignments are:



INEN<x>, bit [x], for x = 0 to 31

Input trigger <n> to output channel <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0b0` Input trigger <n> will not generate an event on output channel <x>.

`0b1` Input trigger <n> will generate an event on output channel <x>.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing the CTIINEN<n>:

CTIINEN<n> can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x020` + 4n	CTIINEN<n>

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.25 CTIINTACK, CTI Output Trigger Acknowledge register

The CTIINTACK characteristics are:

Purpose

Can be used to deactivate the output triggers.

Configurations

CTIINTACK is in the Debug power domain.

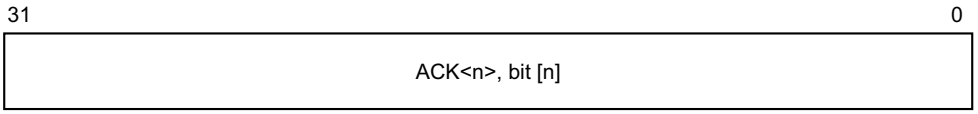
There are no configuration notes.

Attributes

CTIINTACK is a 32-bit register.

Field descriptions

The CTIINTACK bit assignments are:



ACK<n>, bit [n], for n = 0 to 31

Acknowledge for output trigger <n>.

Bits [31:N] are RAZ/WI. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

If any of the following is true, writes to ACK<n> are ignored:

- n >= CTIDEVID.NUMTRIG, the number of implemented triggers.
- Output trigger n is not active.
- The channel mapping function output, as controlled by CTIOUTEN<n>, is still active.

Otherwise, if any of the following are true, it is IMPLEMENTATION DEFINED whether writes to ACK<n> are ignored:

- Output trigger n is not implemented.
- Output trigger n is not connected.
- Output trigger n is self-acknowledging and does not require software acknowledge.

Otherwise, the behavior on writes to ACK<n> is as follows:

`0b0` No effect

`0b1` Deactivate the trigger.

Accessing the CTIINTACK:

A debugger must read CTITRIGOUTSTATUS to confirm that the output trigger has been acknowledged before generating any event that must be ordered after the write to CTIINTACK, such as a write to CTIAPPPULSE to activate another trigger.

CTIINTACK can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x010`	CTIINTACK

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are WI.
- When !SoftwareLockStatus() accesses to this register are WO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.26 CTIITCTRL, CTI Integration mode Control register

The CTIITCTRL characteristics are:

Purpose

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configurations

It is IMPLEMENTATION DEFINED whether CTIITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

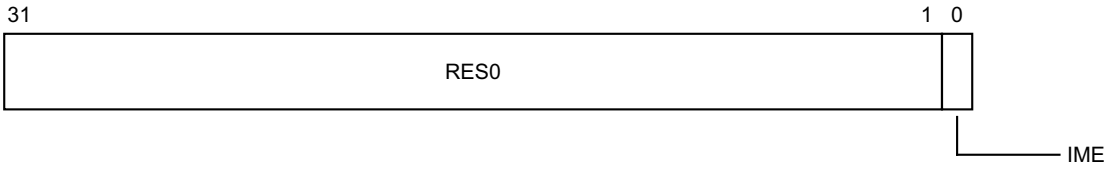
Implementation of this register is OPTIONAL.

Attributes

CTIITCTRL is a 32-bit register.

Field descriptions

The CTIITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0b0` Normal operation.

`0b1` Integration mode enabled.

On a Implementation reset, this field resets to `0`.

Accessing the CTIITCTRL:

CTIITCTRL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xF00`	CTIITCTRL

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register are IMPDEF.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.27 CTILAR, CTI Lock Access Register

The CTILAR characteristics are:

Purpose

Allows or disallows access to the CTI registers through a memory-mapped interface.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Configurations

CTILAR is in the Debug power domain.

If ARMv8.4-Debug is implemented, the Software Lock is not implemented.

Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

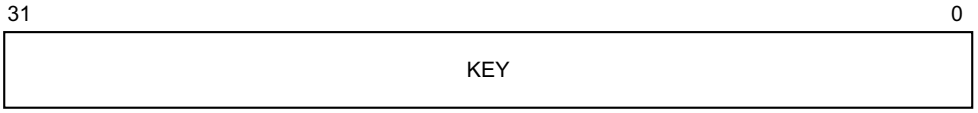
Attributes

CTILAR is a 32-bit register.

Field descriptions

The CTILAR bit assignments are:

When the Software Lock is implemented:

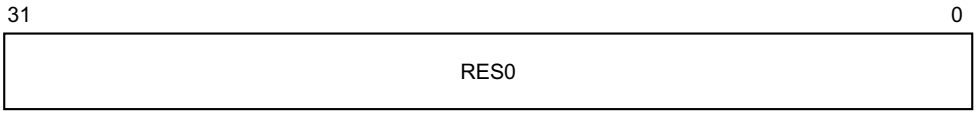


KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Otherwise:



Bits [31:0]

Reserved, RES0.

Accessing the CTILAR:

CTILAR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset	Instance
CTI	`0xFB0`	CTILAR

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are WO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.28 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

Purpose

Indicates the current status of the Software Lock for CTI registers.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Configurations

CTILSR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If ARMv8.4-Debug is implemented, the Software Lock is not implemented.

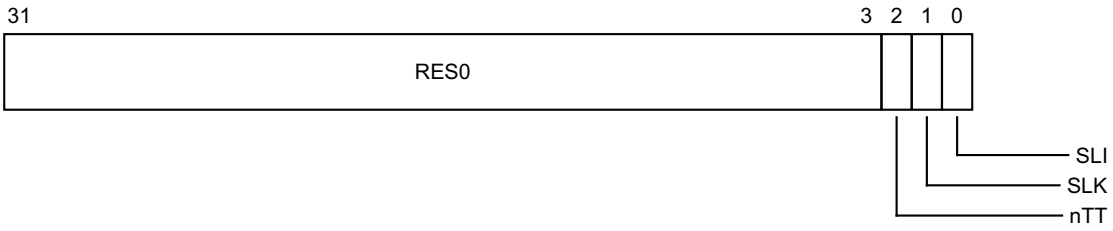
Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILSR is a 32-bit register.

Field descriptions

The CTILSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

When the Software Lock is implemented:

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the Software Lock is implemented, possible values of this field are:

`0b0` Lock clear. Writes are permitted to this component's registers.

`0b1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

On a External debug reset, this field resets to `1`.

Otherwise:

Reserved, RAZ.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0b0` Software Lock not implemented or not memory-mapped access.

`0b1` Software Lock implemented and memory-mapped access.

Accessing the CTILSR:

CTILSR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset	Instance
CTI	`0xFB4`	CTILSR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.29 CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31

The CTIOUTEN<n> characteristics are:

Purpose

Defines which input channels generate output trigger n.

Configurations

CTIOUTEN<n> is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

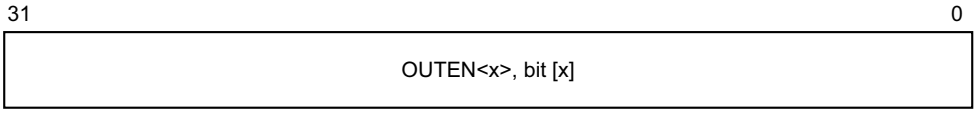
If output trigger n is not connected, the behavior of CTIOUTEN<n> is IMPLEMENTATION DEFINED.

Attributes

CTIOUTEN<n> is a 32-bit register.

Field descriptions

The CTIOUTEN<n> bit assignments are:



OUTEN<x>, bit [x], for x = 0 to 31

Input channel <x> to output trigger <n> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0b0` An event on input channel <x> will not cause output trigger <n> to be asserted.

`0b1` An event on input channel <x> will cause output trigger <n> to be asserted.

On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing the CTIOUTEN<n>:

CTIOUTEN<n> can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x0A0` + 4n	CTIOUTEN<n>

This interface is accessible as follows:

- When SoftwareLockStatus() accesses to this register are RO.
- When !SoftwareLockStatus() accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.30 CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

CTIPIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

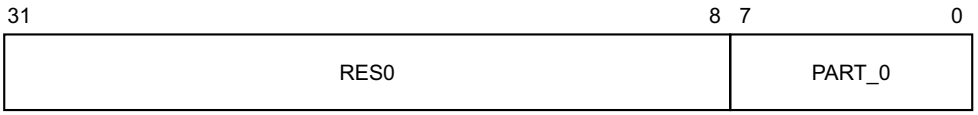
This register is required for CoreSight compliance.

Attributes

CTIPIDR0 is a 32-bit register.

Field descriptions

The CTIPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the CTIPIDR0:

CTIPIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFE0	CTIPIDR0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.31 CTIPIDR1, CTI Peripheral Identification Register 1

The CTIPIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

CTIPIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

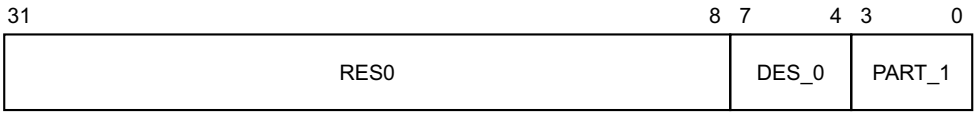
This register is required for CoreSight compliance.

Attributes

CTIPIDR1 is a 32-bit register.

Field descriptions

The CTIPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the CTIPIDR1:

CTIPIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFE4`	CTIPIDR1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.32 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

CTIPIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

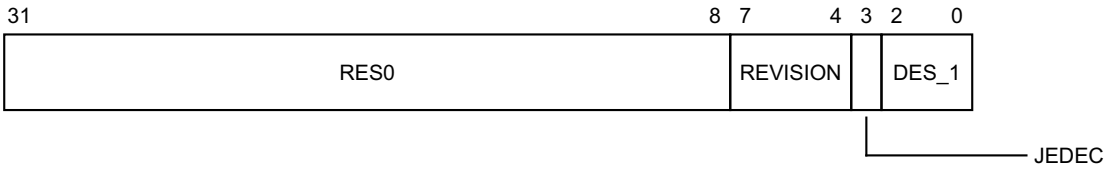
This register is required for CoreSight compliance.

Attributes

CTIPIDR2 is a 32-bit register.

Field descriptions

The CTIPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is `0b011`.

Accessing the CTIPIDR2:

CTIPIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFE8`	CTIPIDR2

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.33 CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

CTIPIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

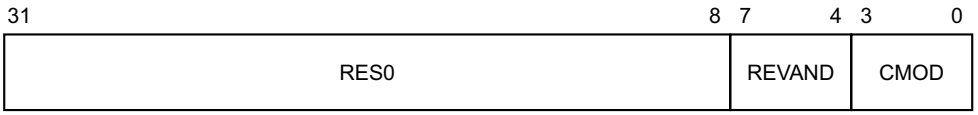
This register is required for CoreSight compliance.

Attributes

CTIPIDR3 is a 32-bit register.

Field descriptions

The CTIPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using CTIPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the CTIPIDR3:

CTIPIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFEC	CTIPIDR3

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.34 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

CTIPIDR4 is in the Debug power domain.

Implementation of this register is OPTIONAL.

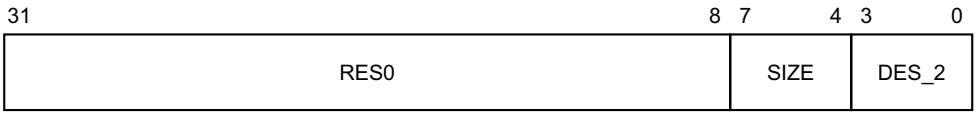
This register is required for CoreSight compliance.

Attributes

CTIPIDR4 is a 32-bit register.

Field descriptions

The CTIPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For Arm Limited, this field is `0b0100`.

Accessing the CTIPIDR4:

CTIPIDR4 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0xFD0`	CTIPIDR4

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.35 CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

Purpose

Provides the status of the trigger inputs.

Configurations

CTITRIGINSTATUS is in the Debug power domain.

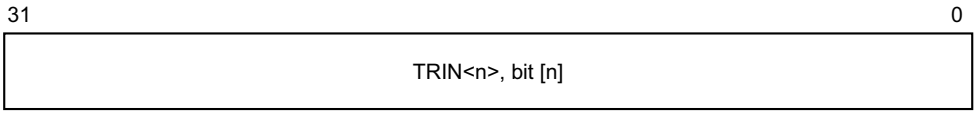
There are no configuration notes.

Attributes

CTITRIGINSTATUS is a 32-bit register.

Field descriptions

The CTITRIGINSTATUS bit assignments are:



TRIN<n>, bit [n], for n = 0 to 31

Trigger input <n> status.

Bits [31:N] are RAZ. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

Possible values of this bit are:

`0b0` Input trigger n is inactive.

`0b1` Input trigger n is active.

Not implemented and not-connected input triggers are always inactive.

It is IMPLEMENTATION DEFINED whether an input trigger that does not support multicycle events can be observed as active.

Accessing the CTITRIGINSTATUS:

CTITRIGINSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x130`	CTITRIGINSTATUS

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

H9.3.36 CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

Purpose

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

Configurations

CTITRIGOUTSTATUS is in the Debug power domain.

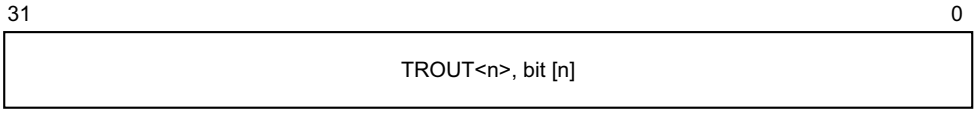
There are no configuration notes.

Attributes

CTITRIGOUTSTATUS is a 32-bit register.

Field descriptions

The CTITRIGOUTSTATUS bit assignments are:



TROUT<n>, bit [n], for n = 0 to 31

Trigger output <n> status.

Bits [31:N] are RAZ. N is the value in CTIDEVID.NUMTRIG.

If n < N, and output trigger <n> is implemented and connected, and either the trigger is not self-acknowledging or the CTI implements multicycle channel events, then permitted values for TROUT<n> are:

`0b0` Output trigger n is inactive.

`0b1` Output trigger n is active.

Otherwise when n < N it is IMPLEMENTATION DEFINED whether TROUT<n> behaves as described here or is RAZ.

Accessing the CTITRIGOUTSTATUS:

CTITRIGOUTSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	`0x134`	CTITRIGOUTSTATUS

This interface is accessible as follows:

- Accesses to this register are RO.

Part I

Memory-mapped Components of the Armv8 Architecture

Chapter I1
Requirements for Memory-mapped Components

This chapter provides some additional information about memory-mapped components. It contains the following sections:

- *Supported access sizes* on page I1-7008.
- *Synchronization of memory-mapped registers* on page I1-7010.
- *Access requirements for reserved and unallocated registers* on page I1-7012.

I1.1 Supported access sizes

The information in this section applies to all accesses to memory-mapped components of the Armv8 architecture, unless a register or component description explicitly states otherwise.

The memory access sizes that are supported by any peripheral are IMPLEMENTATION DEFINED by the peripheral.

When `HaveSecureExtDebugView`() == TRUE, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

An implementation of a memory-mapped component that is compatible with the Armv8 architecture must support the following:

- Word-aligned 32-bit accesses to access 32-bit registers.
- If any PE in the system implements AArch32, word-aligned 32-bit accesses to either half of a 64-bit register that is mapped to a doubleword-aligned pair of adjacent 32-bit locations.

  Note

  Some memory-mapped components of the Armv8 architecture require support for word-aligned 32-bit accesses to either half of a 64-bit memory mapped register regardless of whether any PE in the system implements AArch32. These include:

  — The memory-mapped interface to the external debug and CTI registers that are described in Chapter H9 *External Debug Register Descriptions*.

  — The memory-mapped interfaces to the Generic Timer registers that are described in Chapter I2 *System Level Implementation of the Generic Timer*.

  — The memory-mapped interfaces to the Performance Monitors registers that are described in Chapter I3 *Recommended External Interface to the Performance Monitors*.

- Doubleword-aligned 64-bit accesses to access 64-bit registers that are mapped to a doubleword-aligned pair of adjacent 32-bit locations.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte accesses.
- Halfword accesses.
- Unaligned word accesses. These accesses are not word single-copy atomic.
- Unaligned doubleword accesses. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair that forms a 64-bit register.
- Quadword accesses or higher accesses.
- Exclusive accesses.

For unsupported accesses, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an External abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN values.
- A write is ignored or sets the accessed register or registers to UNKNOWN.
- The access generates a fault handling interrupt or not. A read returns UNKNOWN data.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For memory-mapped accesses from a PE that complies with an Arm architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory that is accessed, determine the size of the access that is made by an instruction. Example I1-1 shows this.

Example I1-1 Access sizes for memory-mapped accesses

Two Load Doubleword instructions that are made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

The Armv8 architecture does not require the size of each element that is accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Unless otherwise specified by the component, any access to a memory-mapped component of the Armv8 architecture is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory type, and only single register load and store instructions, to create memory accesses that are supported by the peripheral. For more information, see *Memory types and attributes* on page B2-143.

I1.2 Synchronization of memory-mapped registers

This section describes the synchronization requirements for the memory-mapped accesses to System registers.

This section refers to accesses to external system control registers as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads and indirect writes.

Note

Synchronization requirements for AArch64 System registers on page D13-2819 and *Synchronization of changes to AArch32 System registers* on page G8-5896 define direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads and external writes as indirect writes.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. Unless otherwise stated, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible as external system control registers.

Unless required to be observable to all observers in finite time, without explicit synchronization, explicit synchronization is normally required following an external write to any register for that write to be observable by:

- A direct access.
- An indirect read by an instruction.
- An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

- The write has completed.
- The PE has executed a Context synchronization event.
- The Context synchronization event was executed after the write completed.

The order and synchronization of direct reads and direct writes of System registers is defined by:

- *Synchronization requirements for AArch64 System registers* on page D13-2819
- *Synchronization of changes to AArch32 System registers* on page G8-5896

The external agent must be able to guarantee completion of a write. For example, the agent can:

- Mark the memory as Device-nGnRnE and executing a DSB barrier, if the system supports this property.
- If the register is read/write and reads are not destructive, read back the value written.
- Use some guaranteed property of the connection between the PE and the external agent.

The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the Context synchronization event, and relying on the memory ordering rules provided by the memory model.

External reads and external write complete in the order in which they arrive at the PE. For accesses to different register locations the external agent must create this order. The agent can:

- Mark the memory as Device-nGnRnE or Device-nGnRE.
- Use the appropriate memory barriers.
- Rely on some guaranteed property of the connection between the PE and the external agent.

However, the external agent cannot force the synchronization of completed writes.

In a simple sequential execution, an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For example, some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means the simultaneous writes must be merged.

I1.3 Access requirements for reserved and unallocated registers

This section describes the access requirements for reserved and unallocated memory-mapped components.

The following information relates to certain types of reserved accesses:

- Reads and writes of unallocated locations. These accesses are reserved for the architecture.
- Reads and writes of locations for features that are not implemented, including:
  - OPTIONAL features that are not implemented.
  - Breakpoints and watchpoints that are not implemented.
  - Performance Monitors counters that are not implemented.
  - CTI triggers that are not implemented.
  - Error records that are not implemented.

  These accesses are reserved.
- Reads of WO locations. These accesses are reserved for the architecture.
- Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses are normally RAZ/WI. However, software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture. Software must treat reserved accesses as RES0.

Chapter I2
System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the Generic Timer. It contains the following sections:

- *About the Generic Timer specification* on page I2-7014.
- *Memory-mapped counter module* on page I2-7016.
- *Memory-mapped timer components* on page I2-7020.

Note

- *Generic Timer memory-mapped register descriptions* on page I5-7151 describes the System level Generic Timer registers. These registers are memory-mapped.
- Appendix K5 *Additional Information for Implementations of the Generic Timer* gives additional information, that does not form part of the architectural definition of a system level implementation of the Generic Timer,
- Chapter D11 *The Generic Timer in AArch64 state* gives a general description of the AArch64 state view of the Generic Timer, and describes the AArch64 System register interface to the Generic Timer.
- Chapter G6 *The Generic Timer in AArch32 state* gives a general description of the AArch32 state view of the Generic Timer, and describes the AArch32 System register interface to the Generic Timer.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I2.1 About the Generic Timer specification

Chapter D11 *The Generic Timer in AArch64 state* describes the Arm Generic Timer and its implementation as seen from AArch64 state. Chapter G6 *The Generic Timer in AArch32 state* describes the Arm Generic Timer and its implementation as seen from AArch32 state. These chapters include the definition of the low-latency System register interface to the Generic Timer. However, the Arm Generic Timer architecture also defines a memory-mapped component, that comprises:

- A memory-mapped counter module, that controls the generation of the Count value used by the Generic Timer.

  This memory-mapped counter module is required in any Arm Generic Timer implementation that requires software control of the Count value of the Generic Timer.

- Optional memory-mapped timer modules. These give a standardized way of providing timers for programmable system components other than PEs that implement the Arm architecture.

The full set of Generic Timer components on page D11-2791 summarizes these components as seen from AArch64 state, and *The full set of Generic Timer components* on page G6-5859 summarizes them as seen from AArch32 state. *The system level components of the Generic Timer* on page I2-7015 summarizes the system level components.

I2.1.1 Registers in the system level implementation of the Generic Timer

Registers that control components of the system level implementation of the Generic Timer are grouped into *frames*. This specification defines the registers in each frame, and their offsets within the frame. The system defines the position of each frame in the memory map. This means the base addresses for each frame is IMPLEMENTATION DEFINED.

Note

The final 12 words of the first or only 4KB block of a register memory frame is an ID block.

Each frame must be in its own memory page, or memory protection region, and must be aligned to the size of the translation granule or protection granule.

Note

When a system level implementation of the Generic Timer is accessed by a PE:

- Using a VMSA, each frame is in its own memory page, aligned to the size of the translation granule.
- Using a PMSA, each frame is in its own memory protection region, aligned to the size of the memory protection granule.

The following sections give more information about the requirements for the system level Generic Timer component:

- *Endianness and supported access sizes*.
- *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Endianness and supported access sizes

All memory-mapped peripherals defined in the Arm architecture must be little-endian. This means the system-level Generic Timer registers, and the register frames, are little-endian.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the memory-mapped Generic Timer registers implementations must:

- Comply with the requirements of *Supported access sizes* on page I1-7008.
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations, even if no PE in the system implements AArch32.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Power and reset domains for the system level implementation of the Generic Timer

The power and reset domains of the system level implementation of the Generic Timer are IMPLEMENTATION DEFINED as part of the system implementation. These domains can be outside the PE power and reset domains defined by the remainder of this manual.

The Arm architecture requires that the CNTCR.{FCREQ, EN} and CNTSR.FCACK fields reset to 0. These reset values apply only on powerup of the power domain in which the registers are implemented or a reset of the reset domain in which they are implemented.

Every other register, or register field, of a system level implementation of the Generic Timer resets to a value that is architecturally UNKNOWN if it has a meaningful reset value. This applies on powerup of the power domain in which the register is implemented, and on a reset of the reset domain in which it is implemented.

I2.1.2 The system level components of the Generic Timer

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, CNTControlBase.
- A status frame, CNTReadBase.

Memory-mapped counter module on page I2-7016 describes this component.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, CNTCTLBase.

The CNTCTLBase frame on page I2-7021 describes this frame.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBase*N* frame.
- Optionally provides an unprivileged view of the timer in the CNTEL0Base*N* frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

The CNTBaseN and CNTEL0BaseN frames on page I2-7022 describes these frames.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I2.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. The CNTControlBase frame holds the registers for the memory-mapped counter, and provides:

- An RW control register CNTCR, that provides:
  - An enable bit for the system counter.
  - An enable bit for Halt-on-debug. For more information, see *Halt-on-debug* on page I2-7018.
  - A field that can be written to request a change to the update frequency of the system counter, with a corresponding change to the increment made at each update. This mechanism means that, for example, if the update frequency is halved, the increment at each update is doubled.

    For more information, see *Control of counter operating frequency and increment* on page I2-7017.

  Writes to this register are rare. In a system that supports two Security states, this register is writable only by Secure writes.

- A RO status register, CNTSR, that provides:
  - A bit that indicates whether the system counter is halted because of an asserted Halt-on-debug signal.
  - A field that indicates the current update frequency of the system counter. This field can be polled to determine when a requested change to the update frequency has been made.

- Two contiguous 32-bit RW registers that hold the current system counter value, CNTCV. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

  The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.

  Writes to these registers are rare. In a system that supports two Security states, these registers are writable only by Secure writes.

- A *Frequency modes table* of one or more 32-bit entries, where:
  - The first entry in the table defines the *base frequency* of the system counter. This is the maximum frequency at which the counter updates.
  - Each subsequent entry in the table defines an alternative frequency of the system counter, that must be an exact divisor of the base frequency.

  A 32-bit zero entry immediately follows the last table entry.

  This table can be RO or RW. For more information, see *The Frequency modes table* on page I2-7017.

In addition, the CNTReadBase frame includes a read-only copy of the system counter value, CNTCV, as two contiguous 32-bit RO registers. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

Counter module control and status register summary on page I2-7018 describes CNTReadBase and CNTControlBase memory maps, and the registers in each frame.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I2.2.1 Control of counter operating frequency and increment

The system counter has a fixed *base frequency*, and must maintain the required counter accuracy, meaning Arm recommends that it does not gain or lose more than ten seconds in a 24-hour period, see *The system counter* on page D11-2792. However, the counter can increment at a lower frequency than the base frequency, using a correspondingly larger increment. For example, it can increment by four at a quarter of the base frequency. Any lower-frequency operation, and any switching between operating frequencies, must not reduce the accuracy of the counter.

Control of the system counter frequency and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- *The Frequency modes table*.
- *Changing the system counter and increment*.

The Frequency modes table

The Frequency modes table starts at offset `0x20` in the CNTControlBase frame.

Table entries are 32-bits, and each entry specifies a system counter update frequency, in Hz.

The first entry in the table specifies the base frequency of the system counter.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

increment = (base_frequency) / (selected_frequency)

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the Frequency modes table is in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the CNTControlBase memory map shows the table region as RO or RW.

Arm strongly recommends that the Frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the Frequency modes table, including the zero-word end marker, and the maximum number of entries is IMPLEMENTATION DEFINED, up to this limit.

Note

- Arm considers it likely that implementations will require significantly fewer entries than the architectural limit.
- In the CNTControlBase frame, the offset range `0x0C0-0x0FC` can be used for IMPLEMENTATION DEFINED registers. If any registers are defined in this space, then the Frequency modes table cannot extend beyond offset `0x0B8`, with a zero word at offset `0x0BC`. This means that if any IMPLEMENTATION DEFINED registers are defined the maximum number of entries in the table is 40, including the zero-word end marker.

Changing the system counter and increment

The value of the CNTCR.FCREQ field specifies which entry in the Frequency modes table specifies the system counter update frequency.

Changing the value of CNTCR.FCREQ requests a change to the system counter update frequency. To ensure the frequency change does not affect the overall accuracy of the counter, a change is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
  1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
  2. Switches to operating at the lower frequency.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When changing from a lower frequency to a higher frequency, the counter:
  1. Waits until the end of the current lower-frequency cycle.
  2. Makes the counter increment required for operation at that lower frequency.
  3. Switches to operating at the higher frequency.

When the frequency has changed, CNTSR is updated to indicate the new frequency. Therefore, a system component that is waiting for a frequency change can poll CNTSR to detect the change.

I2.2.2 Halt-on-debug

The CNTCR register provides an enable bit for an OPTIONAL Halt-on-debug signal.

When the CNTCR.HDBG bit is set to 1, and the Halt-on-debug signal is implemented and asserted, the system counter is halted. Otherwise, the system counter ignores the state of this signal.

Arm recommends that a system counter implements a Halt-on-debug signal that can be controlled by a debugger using the Embedded Cross-Trigger (ECT) using a system-level cross-trigger interface that includes:

- A debug request output trigger event that asserts the Halt-on-debug signal.
- A restart request output trigger event that deasserts the Halt-on-debug signal.

For more information, see *About the Embedded Cross-Trigger (ECT)* on page H5-6790.

Note

Software must use the Halt-on-debug enable bit to ensure that the timers cannot be halted maliciously in an attempt to prohibit progress.

For more information about Halt-on-debug, contact Arm.

I2.2.3 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory *frames*:

- A control frame, with base address CNTControlBase.
- A status frame, with base address CNTReadBase.

Each of these register memory frames is in its own memory page or memory protection region, and the frame base address points to the start of this region. Each base address must be aligned to the size of the translation granule or protection granule.

Note

Each frame of a memory-mapped Generic Timer takes the name of its base address.

In each register memory frame, the memory at offset `0xFD0-0xFFF` is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the CounterID<n> register descriptions for more information.

Note

The Arm architecture requires memory-mapped peripherals to be little-endian, and therefore the counter is little-endian.

In an implementation that supports Secure and Non-secure memory maps, CNTControlBase is accessible only by Secure accesses.

Table I2-1 on page I2-7019 shows the CNTControlBase control registers, in order of their offsets from the CNTControlBase base address, for an implementation that includes registers in the implementation defined register space `0x0C0-0x0FC`, and also has fewer than 39 CNTFID<n> registers. *The Frequency modes table* on page I2-7017 describes how this memory map differs if more CNTFID<n> registers are implemented.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Generic Timer memory-mapped register descriptions on page I5-7151 describes each of these registers.

Table I2-1 CNTControlBase memory map

Offset	Name	Type	Description
0x000	CNTCR	RW	Counter Control Register.
0x004	CNTSR	RO	Counter Status Register.
0x008	CNTCV[31:0]	RW	Counter Count Value register.
0x00C	CNTCV[63:32]	RW	
0x010	CNTSCR[a]	RW	Counter Scale Register.
0x014-0x018	-	RES0	Reserved.
0x01C	CNTID[a]	RO	Counter Identification Register.
0x020	CNTFID0	RO or RW	Frequency modes table, and end marker. For more information, see *The Frequency modes table* on page I2-7017.
0x020+4*n*	CNTFID<n>	RO or RW	
0x024+4*n*	-	RO or RW, RAZ	
(0x028+4*n*)-0x0BC	-	RO, RES0	Reserved.
0x0C0-0x0FC	-	IMPLEMENTATION DEFINED	Reserved for IMPLEMENTATION DEFINED registers.
0x100-0xFCC	-	RO, RES0	Reserved.
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11.

a. Implemented only if ARMv8.4-CNTSC is implemented.

Table I2-2 shows the CNTReadBase control registers, in order of their offsets from the CNTReadBase base address. *Generic Timer memory-mapped register descriptions* on page I5-7151 describes each of these registers.

Table I2-2 CNTReadBase memory map

Offset	Name	Type	Description
0x000	CNTCV[31:0]	RO	Counter Count Value register
0x004	CNTCV[63:32]	RO	
0x008-0xFCC	-	RES0	Reserved
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11

I2.3 Memory-mapped timer components

This part of the Arm Generic Timer specification defines an optional memory-mapped timer component. This can be implemented as part of any programmable system component that does not incorporate a System register mapped Arm Generic Timer, to provide that system component with the timer functionality of an Arm Generic Timer.

The memory map consists of up to eight timer *frames*. The base address of a frame is CNTBaseN, where *N* numbers from 0 up to a maximum permitted value of 7.

Each CNTBaseN timer frame:

- Provides its own set of timers and associated interrupts.
- Is implemented in its own memory page or memory protection region.
- Is implemented at a base address, identified as CNTBaseN, that is aligned to the size of the translation granule or memory protection region.

For each implemented CNTBaseN frame the system can optionally provide an unprivileged view of the frame, described as the EL0 view of the frame. The base address of this second view of the CNTBaseN frame is CNTEL0BaseN.

Note

In the naming of the registers associated with a CNTBaseNor CNTEL0BaseN frame, the value of *N* is represented as <n>, for example CNTACR<n>.

If a CNTEL0BaseN frame is implemented:

- Is implemented in its own memory page or memory protection region and is aligned to the size of the translation granule or memory protection region.
- All registers visible in CNTBaseN, except for CNTVOFF and CNTEL0ACR, can be visible in CNTEL0BaseN.
  - Control fields in CNTEL0ACR determine whether each register is visible.
- The offsets of all visible registers are the same as their offsets in the CNTBaseN frame.

In addition to the implemented CNTBaseN and CNTEL0BaseN frames, the system must provide a single control frame at base address CNTCTLBase. CNTCTLBase must be implemented in its own memory page or memory protection region and is aligned to the size of the translation granule or memory protection region.

The system defines the position of each frame in the memory map. This means the values of each of the CNTBaseN, CNTEL0BaseN, and CNTCTLBase base addresses is IMPLEMENTATION DEFINED.

Note

The Arm architecture requires memory-mapped peripherals to be little-endian, and therefore the memory-mapped timers are little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

- *The CNTCTLBase frame* on page I2-7021.
- *The CNTBaseN and CNTEL0BaseN frames* on page I2-7022.

Note

Providing a complete set of features in a system level implementation on page K5-7686 gives an implementation example for a system level Generic Timer implementation that provides equivalent features to a System registers Generic Timer implementation in a PE that includes all of the Exception levels.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I2.3.1 The CNTCTLBase frame

The CNTCTLBase frame contains:

- An identification register for the features of the memory-mapped counter and timer implementation.
- Access controls for each CNTBaseN frame.
- A virtual offset register for frames that implement a virtual timer.

Table I2-3 shows the CNTCTLBase registers, in order of their offsets from the CNTCTLBase base address.

Note

CNTFRQ and CNTVOFF registers are also implemented in a System register interface to the Generic Timer.

Generic Timer memory-mapped register descriptions on page I5-7151 describes each of these registers.

Table I2-3 CNTCTLBase memory map

Offset	Register	Type	Security[a]	Description
0x000	CNTFRQ[b]	RW	Secure only	Counter Frequency register.
0x004	CNTNSAR	RW	Secure only	Counter Non-Secure Access register.
0x008	CNTTIDR	RO	Both	Counter Timer ID register.
0x00C- 0x03F	-	RES0	-	Reserved.
0x040+4*N*[c]	CNTACR<n>	RW	Configurable[d]	Counter Access Control register *N*.
0x060- 0x07F	-	RES0	-	Reserved.
0x080+8*N*[c]	CNTVOFF<n>[31:0][b]	RW[e]	Configurable[d]	Virtual Offset register *N*. If the CNTBaseN frame has virtual timer capability then CNTVOFFis implemented as an RW register, otherwise its location is RAZ/WI.
0x084+8*N*[c]	CNTVOFF<n>[63:32][b]	RW[e]		
0x0C0-0x0FC	-	RES0	-	Reserved.
0x100-0x7FC	-	-	-	IMPLEMENTATION DEFINED.
0x800-0xFBC	-	RES0	-	Reserved.
0xFC0-0xFCF	-	-	-	IMPLEMENTATION DEFINED.
0xFD0- 0xFFC	CounterID<n>	RO	Both	Counter ID registers 0-11.

a. Access security requirement in an implementation that supports two Security states. In an implementation that does not support multiple Security states all registers are accessible as shown in the *Type* column.

b. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers* on page D13-3685 and *Generic Timer registers* on page G8-6627. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

c. Implemented for each value of *N* from 0 to 7 for which a CNTBaseN frame is implemented.

d. The CNTNSAR determines the Non-secure accessibility of the CNTACR<n>s and the CNTVOFF<n> in the CNTCTLBase frame. For more information, see the register descriptions.

e. Address is reserved, RAZ/WI if register not implemented.

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF register that defines the virtual offset between the physical count and the virtual count. If a memory-mapped Generic Timer component does not distinguish between real time and virtual time, then it can implement CNTVOFF as RAZ/WI. Otherwise CNTVOFF is an RW register, and Arm strongly recommends that the system only permits access to CNTVOFF from EL2 or higher.

I2.3.2 The CNTBaseN and CNTEL0BaseN frames

Each CNTBaseN frame, or {CNTBaseN, CNTEL0BaseN} pair of frames, provides a memory-mapped counter and timer, see:

- *The CNTBaseN frame*.
- *The CNTEL0BaseN frame* on page I2-7023.
- *CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-7023.

The CNTBase*N* frame

Table I2-4 shows the CNTBaseN registers, in order of their offsets from the CNTBaseN base address. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not, then memory at offsets `0x030-0x03C` is RAZ/WI. Except for CNTEL0ACR and the CounterID<n> registers, equivalent registers are also implemented in a System register interface to the timer component of a Generic Timer.

Generic Timer memory-mapped register descriptions on page I5-7151 describes each of these registers.

Table I2-4 CNTBase*N* memory map

Offset	Register	Type	Description
`0x000`	CNTPCT[31:0][a]	RO	Physical Count register.
`0x004`	CNTPCT[63:32][a]	RO	
`0x008`	CNTVCT[31:0][a]	RO	Virtual Count register.
`0x00C`	CNTVCT[63:32][a]	RO	
`0x010`	CNTFRQ[a]	RO[c]	Counter Frequency register.
`0x014`	CNTEL0ACR	RW[b]	Counter EL0 Access Control Register, optional in the CNTBaseN memory map.
`0x018`	CNTVOFF[31:0][a]	RO[c]	Virtual Offset register. If CNTVOFFin the CNTCTLBase frame is an RW register, a read of this register returns the value of that register. Otherwise is RAZ.
`0x01C`	CNTVOFF[63:32][a]	RO[c]	
`0x020`	CNTP_CVAL[31:0][a]	RW	Physical Timer CompareValue register.
`0x024`	CNTP_CVAL[63:32][a]	RW	
`0x028`	CNTP_TVAL[a]	RW	Physical TimerValue register.
`0x02C`	CNTP_CTL[a]	RW	Physical Timer Control register.
`0x030`	CNTV_CVAL[31:0][a]	RW[b]	Virtual Timer CompareValue register, optional in the CNTBaseN memory map.
`0x034`	CNTV_CVAL[63:32][a]	RW[b]	
`0x038`	CNTV_TVAL[a]	RW[b]	Virtual TimerValue register, optional in the CNTBaseN memory map.
`0x03C`	CNTV_CTL[a]	RW[b]	Virtual Timer Control register, optional in the CNTBaseN memory map.
`0x040-0xFCF`	-	RES0	Reserved.
`0xFD0-0xFFC`	CounterID<n>	RO	Counter ID registers 0-11.

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers* on page D13-3685 and *Generic Timer registers* on page G8-6627. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. Address is reserved, RAZ/WI if register not implemented.

c. The CNTCTLBase frame includes an RW view of this register.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The CNTEL0Base*N* frame

For any value of *N*, the layout of the registers in the CNTEL0Base*N* frame is identical to the CNTBaseN frame, except that, in the CNTEL0Base*N* frame:

- CNTVOFF is never visible, and the memory at `0x018-0x01C` is RAZ/WI.
- CNTEL0ACR is never visible, and the memory at `0x014` is RAZ/WI.
- If implemented in the CNTBaseN frame, CNTEL0ACR controls whether CNTPCT, CNTVCT, CNTFRQ, the Physical Timer, and the Virtual Timer registers are visible in the CNTEL0BaseN frame.

  If CNTEL0ACR is not implemented then these registers are not visible in the CNTEL0BaseN frame, and their addresses in that frame are RAZ/WI.

If an implementation supports 64-bit atomic accesses, then CNTPCT, CNTVCT, CNTVOFF, CNTP_CVAL, and CNTV_CVAL must be accessible as atomic 64-bit values.

CNTCTLBase status and control fields for the CNTBase*N* and CNTEL0Base*N* frames

In the CNTCTLBase frame:

CNTTIDR controls:

- Whether each CNTBaseN frame is implemented.
- If a CNTBaseN frame is implemented, whether:
  - That CNTBaseN frame has virtual timer capability.
  - A corresponding CNTEL0BaseN frame is implemented.

CNTNSAR controls:

In an implementation that recognizes two Security states, determines whether each implemented CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

This control also determines whether, in the CNTCTLBase frame, the CNTACR<n> and CNTVOFF<n> registers are accessible by Non-secure accesses.

The CNTACR<n> registers control:

For each implemented CNTBaseN frame, the accessibility of the following registers in that frame:

- CNTP_CTL, CNTP_CVAL, and CNTP_TVAL.
- CNTV_CTL, CNTV_CVAL, and CNTV_TVAL.
- CNTVOFF.
- CNTFRQ.
- CNTPCT.
- CNTVCT.

For CNTACR<n>, the value of <n> corresponds to the value of *N* for the controlled CNTBaseN frame.

The CNTVOFF<n> registers provide:

For each implemented CNTBaseN frame that has virtual capability, the RW copy of the CNTVOFF register for that frame.

Note

In a CNTBaseN frame that has virtual timer capability the CNTVOFF register is RO.

For CNTVOFF<n>, the value of <n> corresponds to the value of *N* for the controlled CNTBaseN frame.

Chapter I3
Recommended External Interface to the Performance Monitors

This chapter describes the recommended external interface to the Performance Monitors. It contains the following section:

- *About the external interface to the Performance Monitors registers* on page I3-7026.

Note

Performance Monitors external register descriptions on page I5-7039 describes the external view of the Performance Monitors registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I3.1 About the external interface to the Performance Monitors registers

Arm recommends that:

- An implementation provides the OPTIONAL external debug interface to the Performance Monitors registers.

  Note

  A debugger can use this interface to access counters in the Performance Monitors.

- The implementation includes the OPTIONAL support for memory-mapped access to the External debug interface.

  Note

  — Software running on any PE in a system can use this interface to access counters in the Performance Monitors.

  — Privileged software should use the MMU to control access to this interface.

- The external debug interface is implemented as defined in Appendix K2 *Recommended External Debug Interface*.

The following sections describe the memory-mapped views of the Performance Monitors registers:

- *Differences in the external views of the Performance Monitors registers*.
- *Synchronization of changes to the memory-mapped views* on page I3-7027.
- *Access permissions for external views of the Performance Monitors* on page I3-7027.

In this section, unless the context explicitly indicates otherwise, any reference to *a memory-mapped view* applies equally to a register view using:

- An access through an external debug interface.
- A memory-mapped access.

I3.1.1 Endianness and supported access sizes

When an implementation supports memory-mapped access to the external debug interface the interface is accessed as a little-endian memory-mapped peripheral. *External Performance Monitors registers summary* on page I5-7036 gives the memory map of these registers.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the external interface to the Performance Monitors registers implementations must:

- Comply with the requirements of *Supported access sizes* on page I1-7008.
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations, even if no PE in the system implements AArch32.

I3.1.2 Differences in the external views of the Performance Monitors registers

An external view of the Performance Monitors registers accesses the same registers as the System registers interface described in *Performance Monitors Extension registers* on page D7-2723, except that:

1. The PMSELR is accessible only in the System registers interface.
2. The following registers are accessible only in external views:
   - PMCFGR
   - PMDEVAFF0
   - PMDEVAFF1
   - PMLAR
   - PMLSR
   - PMAUTHSTATUS

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- PMDEVARCH
- PMDEVTYPE
- PMPIDR0
- PMPIDR1
- PMPIDR2
- PMPIDR3
- PMPIDR4
- PMCIDR0
- PMCIDR1
- PMCIDR2
- PMCIDR3

Performance Monitors external register descriptions on page I5-7039 describes these registers.

3. The following controls do not affect the external views:
   - PMSELR.
   - PMUSERENR.
   - HDCR.{TPM, TPMCR, HPMN}.

   Instead, see the register descriptions in Chapter I5 *External System Control Register Descriptions*.

I3.1.3 Synchronization of changes to the memory-mapped views

Synchronization must comply with *Synchronization of memory-mapped registers* on page I1-7010.

In particular, if a Performance Monitor is visible in both System register and an external view, and is accessed simultaneously through these two mechanisms, the behavior must be as if the access occurred atomically in any order. For more information, see *Synchronization of changes to the external debug registers* on page H8-6828.

I3.1.4 Access permissions for external views of the Performance Monitors

For more information, see *External debug interface register access permissions* on page H8-6835.

Table I3-1 on page I3-7028 shows the access permissions for the Performance Monitors registers in a v8 Debug implementation. This table uses the following terms:

DLK When ARMv8.0-DoubleLock is implemented and locked, `DoubleLockStatus()` == TRUE, accesses to some registers produce an error. Applies to both interfaces.

EPMAD When `AllowExternalPMUAccess()` == FALSE, external debug access is disabled for the access. If ARMv8.4-Debug is implemented, this applies only for Non-secure access to the register. See also *Behavior of a not permitted memory-mapped access* on page H8-6833.

Error Indicates that the access gives an error response.

Default This shows the default access permissions, if none of the conditions in this list prevent access to the register.

Off The Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed, and EDPRSR.PU will read as zero.

Note

If debug power is off, then all external debug interface accesses return an error.

OSLK When the OS Lock is locked, OSLAR_EL1.OSLK == 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.

SLK This indicates the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the optional Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-6832.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For all other accesses, this column is ignored.

- Indicates that the control has no effect on the behavior of the access:
  - If no other control affects the behavior, the Default access behavior applies.
  - However, another control might determine the behavior.

Table I3-1 Access permissions for the Performance Monitors registers

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0x000+8xn	PMEVCNTR<n>_EL0[a]	Core	Error	Error	Error	Error	RW	RO

Table I3-1 Access permissions for the Performance Monitors registers (continued)

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0xE40	PMMIR	Core	Error	Error	Error	Error	RO	RO
0xE80-0xEFC	Integration registers	-	Access is IMPLEMENTATION DEFINED					
0xF00-0xFFC	*Management registers and CoreSight compliance* on page K2-7655							

a. Implemented counters only. *n* is the counter number.
b. Implemented only if ARMv8.2-PCSample is implemented. See Chapter H7 *The PC Sample-based Profiling Extension*.
c. Only if the OPTIONAL PMSWINC_EL0 register is implemented in the external debug interface.

I3.1.5 Power domains and Performance Monitors registers reset

For Armv8-A implementations, Arm recommends that Performance Monitors are implemented as part of the Core power domain, not as part of a separate Debug power domain. There is no interface to access the Performance Monitors registers when the Core power domain is powered down.

A Warm or Cold reset sets the Performance Monitors registers to their reset values. An External Debug reset does not change the values of the Performance Monitors registers.

For more information about the reset scheme recommended for a v8 Debug implementation see Chapter H6 *Debug Reset and Powerdown Support*.

Table I3-2 shows the Performance Monitors register resets for writable register fields. The column headings use the following terms:

64 This is the architectural reset value when resetting into AArch64 state.

32 This is the architectural reset value when resetting into AArch32 state.

- This indicates an IMPLEMENTATION DEFINED reset value on the specified reset. This might be UNKNOWN.

Note

This table does not include:

- Read-only identification registers and fields that have a fixed value. In this case, the reset value is that fixed value. An example of this is PMCR_EL0.N.
- Write-only registers and fields that only have an effect on writes. These do not have a reset value. An example of this is PMSWINC_EL0.
- IMPLEMENTATION DEFINED registers. In this case, the reset domains are IMPLEMENTATION DEFINED. The reset values are IMPLEMENTATION DEFINED and might be UNKNOWN.

Table I3-2 Performance Monitors System register resets

Register	Domain	Field	64	32	Description
PMCR_EL0	Warm	DP	-	0	Disable PMCCNTR_EL0 when prohibited
		X	-	0	Export enable
		D	-	0	Clock divider
		E	0	0	Performance Monitors enable

Chapter I4
Recommended External Interface to the Activity Monitors

This chapter describes the optional external interface to the Activity Monitors Extension registers. It contains the following section:

- *About the external interface to the Activity Monitors Extension registers* on page I4-7032

Note

Activity Monitors external register descriptions on page I5-7115 describes the external view of the Activity Monitors Extension registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I4.1 About the external interface to the Activity Monitors Extension registers

If an implementation supports the Activity Monitors Extension, it may optionally support an external memory-mapped interface to the Activity Monitors Extension, and, if so, may further optionally support CoreSight device registers and ID registers.

The memory access sizes supported by the memory-mapped interface are IMPLEMENTATION DEFINED and comply with the requirements of *Supported access sizes* on page I1-7008.

The base address of the memory-mapped view is aligned to a 4KB boundary, but is otherwise IMPLEMENTATION DEFINED. The address offsets for the memory-mapped view are given in Table I5-2 on page I5-7113.

I4.1.1 Differences in the external views of the Activity Monitors Extension registers

The external memory-mapped interface view of the Activity Monitors Extension registers accesses the same registers as the System registers interface to the registers, except that:

- AMUSERENR is accessible only in the System registers interface.
- If implemented, the following registers are accessible only in the memory-mapped view:
  - AMIIDR
  - AMDEVAFF0
  - AMDEVAFF1
  - AMDEVARCH
  - AMDEVTYPE
  - AMPIDR0
  - AMPIDR1
  - AMPIDR2
  - AMPIDR3
  - AMPIDR4
  - AMCIDR0
  - AMCIDR1
  - AMCIDR2
  - AMCIDR3

  Activity Monitors external register descriptions on page I5-7115 describes these registers.

I4.1.2 Access during reset and power transitions

As described in *Power and reset domains* on page D8-2727, the power and reset domains of the activity monitoring unit are IMPLEMENTATION DEFINED, and when a Cold reset of the power domain of the activity monitoring unit occurs, the activity monitoring unit is reset and the counters are reset to zero.

If the power domain of the activity monitoring unit is an always-on power domain, while the PE is reset or powered down counter values may be preserved and might be accessible by memory-mapped access.

If the power domain of the activity monitoring unit is the Core power domain, while the PE is reset or powered down and when a memory-mapped access occurs, the access reads as zero and the bus access completes without an error.

Chapter I5
External System Control Register Descriptions

This chapter describes the external system control registers. It excludes the External debug registers that are described in Chapter H9 *External Debug Register Descriptions*. It contains the following sections:

- *About the external system control register descriptions* on page I5-7034.
- *External Performance Monitors registers summary* on page I5-7036.
- *Performance Monitors external register descriptions* on page I5-7039.
- *External Activity Monitors Extension registers summary* on page I5-7113.
- *Activity Monitors external register descriptions* on page I5-7115.
- *Generic Timer memory-mapped registers overview* on page I5-7150.
- *Generic Timer memory-mapped register descriptions* on page I5-7151.
- *RAS Registers* on page I5-7199.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.1 About the external system control register descriptions

This chapter describes the external system control registers other than the external debug registers. That is, it describes:

An external view of the Performance Monitors registers

Arm recommends that implementations provide access to the Performance Monitors registers through the OPTIONAL External debug interface, and provide the OPTIONAL memory-mapped interface to this interface:

- *External Performance Monitors registers summary* on page I5-7036 lists the registers that are accessible in this view of the Performance Monitors, and describes their memory map.
- *Performance Monitors external register descriptions* on page I5-7039 describes each of the memory-mapped registers.

Chapter I3 *Recommended External Interface to the Performance Monitors* describes the recommended interface to these registers.

Note

Chapter D7 *The Performance Monitors Extension* describes the Performance Monitors. The following sections describe the System register interfaces to the Performance Monitors:

- *Performance Monitors registers* on page D13-3526, for accesses from an Exception level that is using AArch64.
- *Performance Monitors registers* on page G8-6479, for accesses from an Exception level that is using AArch32.

An external view of the Activity Monitors Extension registers

An implementation which supports the Activity Monitors Extension may support an optional external memory-mapped interface to the Activity Monitors Extension registers.

- *External Activity Monitors Extension registers summary* on page I5-7113 lists the registers that are accessible in this view of the Performance Monitors, and describes their memory map.
- *Activity Monitors external register descriptions* on page I5-7115 describes each of the memory-mapped registers.

Chapter I3 *Recommended External Interface to the Performance Monitors* describes the recommended interface to these registers.

Note

Chapter D8 *The Activity Monitors Extension* describes the Activity Monitors. The following sections describe the System register interfaces to the Activity Monitors:

- *Activity Monitors registers* on page D13-3584, for accesses from an Exception level that is using AArch64.
- *Activity Monitors registers* on page G8-6542, for accesses from an Exception level that is using AArch32.

The registers for the system level Generic Timer component

Any implementation that includes the Generic Timer must include the memory-mapped system level component described in Chapter I2 *System Level Implementation of the Generic Timer*. In this chapter:

- *Generic Timer memory-mapped registers overview* on page I5-7150 gives an overview of the registers, referring to Chapter I2 for more information.
- *Generic Timer memory-mapped register descriptions* on page I5-7151 describes each of the memory-mapped registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Chapter D11 *The Generic Timer in AArch64 state* describes the Generic Timer component that is accessible using the System registers. The following sections describe the System register interfaces to that component:

- *Generic Timer registers* on page D13-3685, for accesses from an Exception level that is using AArch64.
- *Generic Timer registers* on page G8-6627, for accesses from an Exception level that is using AArch32.

Note

Chapter H9 *External Debug Register Descriptions* describes the external debug registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.2 External Performance Monitors registers summary

When an implementation provides access to the Performance Monitors registers through the External debug interface, that interface provides access to:

- Performance Monitors System registers.
- A read-only configuration register, PMCFGR.
- The OPTIONAL CoreSight registers for the Performance Monitors, if they are implemented.

The locations of the registers are defined as offsets from a system-defined base address. *Performance Monitors external register views* defines this memory map.

I5.2.1 Performance Monitors external register views

Table I5-1 shows the external view of the Performance Monitors registers. All other entries are reserved.

Note

- Counters that are reserved because HDCR.HPMN has been changed from its reset value remain visible in any external view.
- The registers that relate to an implemented event counter, PMN*x*, are PMEVCNTR<n> and PMEVTYPER<n>.
- The mapping of the *Performance Monitors Event Counter Registers*, at offsets `0x000-0x0F4`, has changed compared to the mappings of the equivalent registers in Armv7.

Each entry in the Name column links to the register description in *Performance Monitors external register descriptions* on page I5-7039, and:

- If the *System register?* column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
  - *Performance Monitors registers* on page D13-3526, for the AArch64 System register.
  - *Performance Monitors registers* on page G8-6479, for the AArch32 System register.
- Otherwise, the register is accessible only using the external interface.

Table I5-1 Performance Monitors external register views (continued)

Name	Type	Description	System register?	Offset
PMCIDR0[c]	RO	Component ID registers	No	0xFF0
PMCIDR1[c]	RO			0xFF4
PMCIDR2[c]	RO			0xFF8
PMCIDR3[c]	RO			0xFFC

a. The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.

b. PC Sample-based Profiling Extension registers. Implemented only when ARMv8.2-PCSample is implemented, except that from Armv8.2 PMDEVIDt is required regardless of whether ARMv8.2-PCSample is implemented.

Before Armv8.2. the PC Sample-based Profiling Extension can, instead, be implemented in the memory-mapped debug registers space, see Chapter H7 *The PC Sample-based Profiling Extension*.

c. CoreSight interface registers, see *Management registers and CoreSight compliance* on page K2-7655.

d. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

I5.3 Performance Monitors external register descriptions

This section describes the external view of the Performance Monitors registers. *External Performance Monitors registers summary* on page I5-7036 lists these registers in offset order.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

Configurations

It is IMPLEMENTATION DEFINED whether PMAUTHSTATUS is implemented in the Core power domain or in the Debug power domain.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

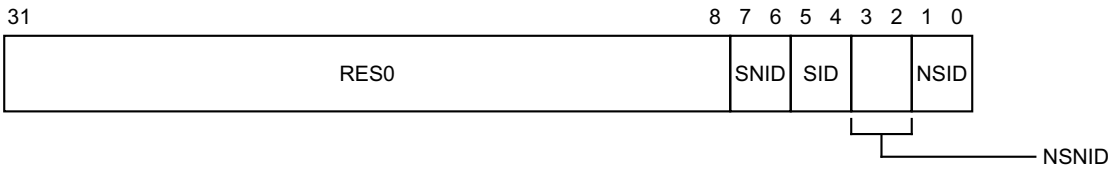
This register is OPTIONAL, and is required for CoreSight compliance. Arm recommends that this register is implemented.

Attributes

PMAUTHSTATUS is a 32-bit register.

Field descriptions

The PMAUTHSTATUS bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Holds the same value as DBGAUTHSTATUS_EL1.SNID.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

`0b00` Not implemented.

All other values are reserved.

NSNID, bits [3:2]

Holds the same value as DBGAUTHSTATUS_EL1.NSNID.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

`0b00` Not implemented.

All other values are reserved.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMAUTHSTATUS:

PMAUTHSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xFB8	PMAUTHSTATUS

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.2 PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

Configurations

External register PMCCFILTR_EL0[31:0] is architecturally mapped to AArch64 System register PMCCFILTR_EL0[31:0].

External register PMCCFILTR_EL0[31:0] is architecturally mapped to AArch32 System register PMCCFILTR[31:0].

PMCCFILTR_EL0 is in the Core power domain.

On a Warm or Cold reset RW fields in this register reset:

- To architecturally UNKNOWN values if the reset is to an Exception level that is using AArch64.
- To 0 if the reset is to an Exception level that is using AArch32.

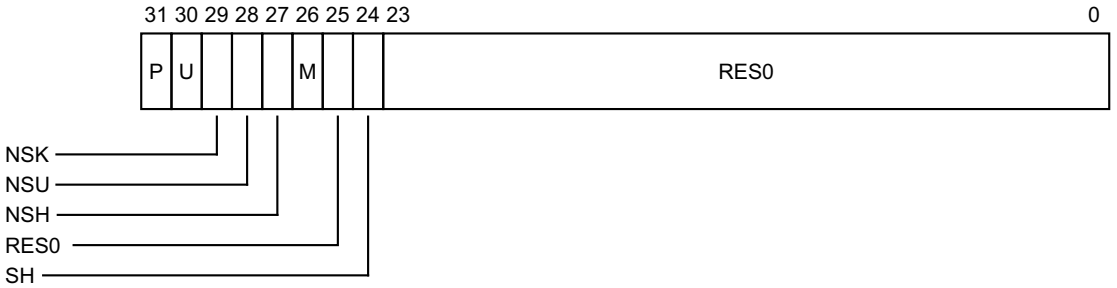
The register is not affected by an External debug reset.

Attributes

PMCCFILTR_EL0 is a 32-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:



P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMCCFILTR_EL0.NSK bit. The possible values of this bit are:

`0b0` Count cycles in EL1.

`0b1` Do not count cycles in EL1.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMCCFILTR_EL0.NSU bit. The possible values of this bit are:

`0b0` Count cycles in EL0.

`0b1` Do not count cycles in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMCCFILTR_EL0.U bit, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

NSH, bit [27]

EL2 (Hypervisor) filtering bit. Controls counting in EL2. If EL2 is not implemented, this bit is RES0. If Secure EL2 is implemented, counting in Secure EL2 is further controlled by the PMCCFILTR_EL0.SH bit.

`0b0` Do not count cycles in EL2.

`0b1` Count cycles in EL2.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMCCFILTR_EL0.P bit, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

Note

This field is not visible in the AArch32 PMCCFILTR System register.

Bit [25]

Reserved, RES0.

SH, bit [24]

When ARMv8.4-SecEL2 is implemented:

Secure EL2 filtering.

If the value of this bit is not equal to the value of the PMCCFILTR_EL0.NSH bit, cycles in Secure EL2 are counted.

Otherwise, cycles in Secure EL2 are not counted.

If Secure EL2 is not implemented or is disabled, this field is RES0.

Note

This field is not visible in the AArch32 PMCCFILTR System register.

Otherwise:

Reserved, RES0.

Bits [23:0]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMCCFILTR_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCCFILTR_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0x47C	PMCCFILTR_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.3 PMCCNTR_EL0, Performance Monitors Cycle Counter

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See *Time as measured by the Performance Monitors cycle counter* on page D7-2671 for more information.

PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

Configurations

External register PMCCNTR_EL0[63:0] is architecturally mapped to AArch64 System register PMCCNTR_EL0[63:0].

External register PMCCNTR_EL0[63:0] is architecturally mapped to AArch32 System register PMCCNTR[63:0].

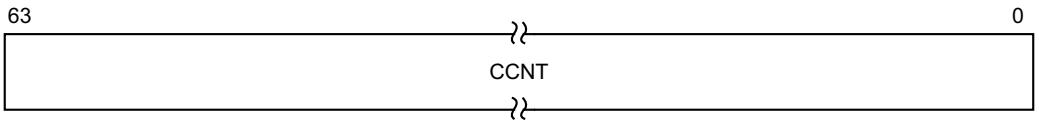
PMCCNTR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

The PMCCNTR_EL0 bit assignments are:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMCCNTR_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCCNTR_EL0[31:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
PMU	0x0F8	PMCCNTR_EL0	31:0

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to PMCCNTR_EL0[31:0] are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to PMCCNTR_EL0[31:0] are RW.
- Otherwise accesses to PMCCNTR_EL0[31:0] generate an error response.

PMCCNTR_EL0[63:32] can be accessed through the external debug interface:

Component	Offset	Instance	Range
PMU	0x0FC	PMCCNTR_EL0	63:32

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to PMCCNTR_EL0[63:32] are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to PMCCNTR_EL0[63:32] are RW.
- Otherwise accesses to PMCCNTR_EL0[63:32] generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.4 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range `0x0000` to `0x001F`

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D7-2693.

Note

- Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.
- This view of the register was previously called PMCEID0_EL0.

Configurations

External register PMCEID0[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[31:0].

External register PMCEID0[31:0] is architecturally mapped to AArch32 System register PMCEID0[31:0].

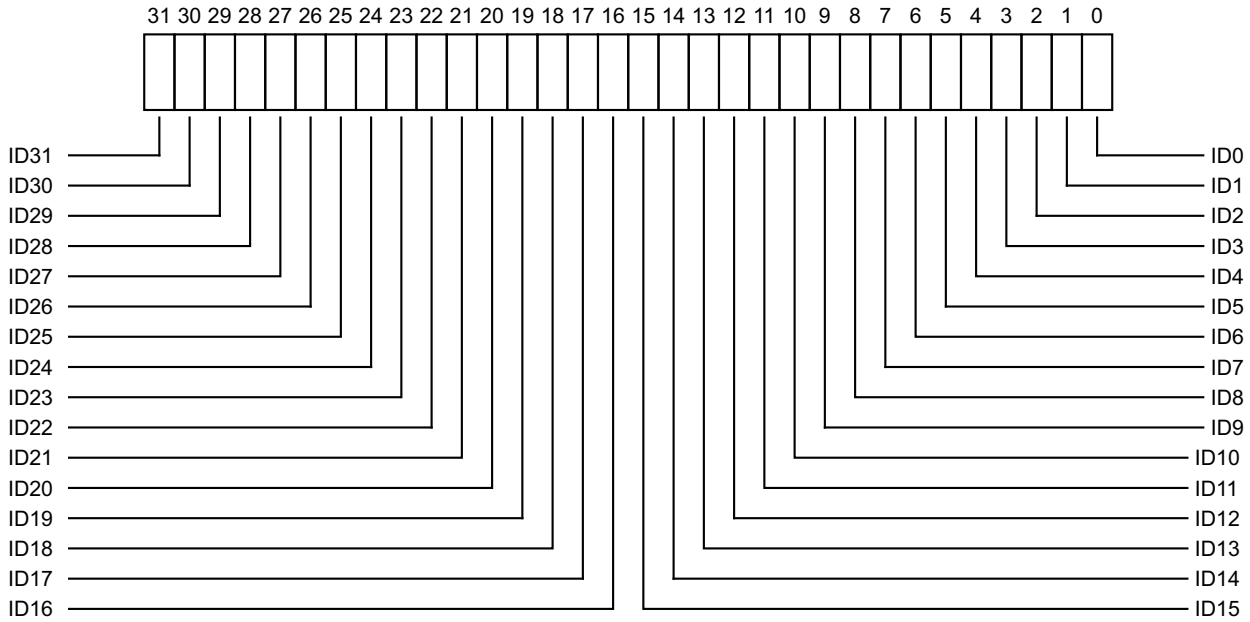
PMCEID0 is in the Core power domain.

Attributes

PMCEID0 is a 32-bit register.

Field descriptions

The PMCEID0 bit assignments are:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event n.

For each bit:

`0b0` The common event is not implemented, or not counted.

`0b1` The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing the PMCEID0:

Note

AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xE20`	PMCEID0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.5 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range `0x020` to `0x03F`.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D7-2693.

Note

- Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.
- This view of the register was previously called PMCEID1_EL0.

Configurations

External register PMCEID1[31:0] is architecturally mapped to AArch64 System register PMCEID1_EL0[31:0].

External register PMCEID1[31:0] is architecturally mapped to AArch32 System register PMCEID1[31:0].

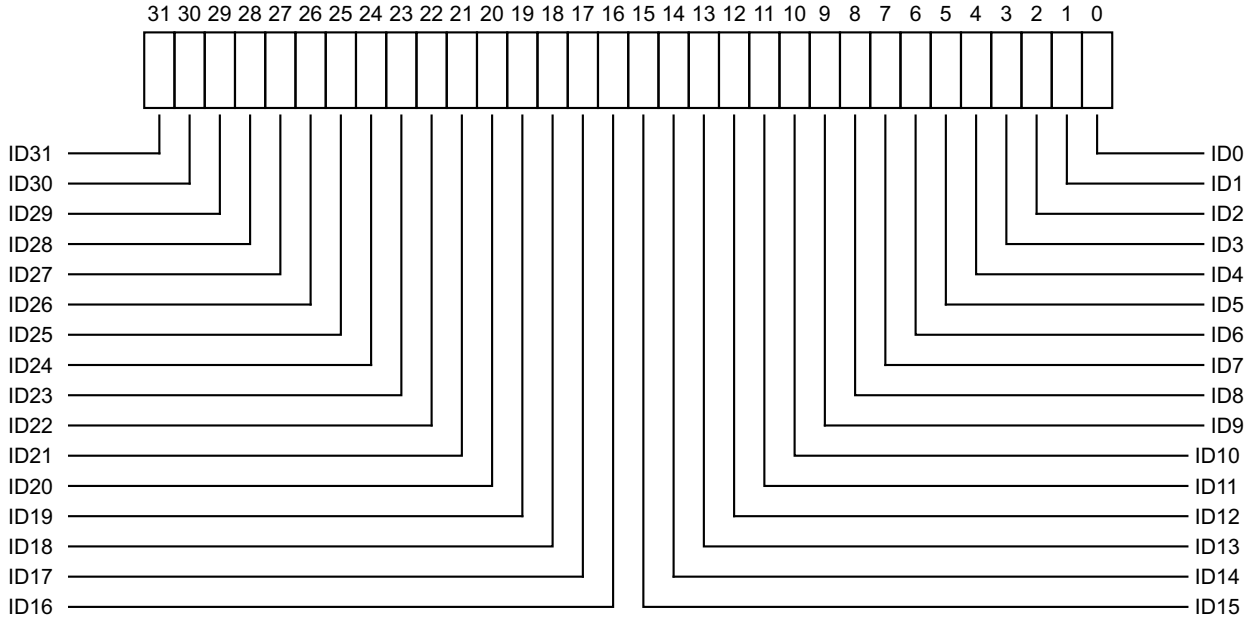
PMCEID1 is in the Core power domain.

Attributes

PMCEID1 is a 32-bit register.

Field descriptions

The PMCEID1 bit assignments are:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ID<n>, bit [n], for n = 0 to 31

ID[n] corresponds to common event (0x0020 + n).

For each bit:

0b0 The common event is not implemented, or not counted.

0b1 The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing the PMCEID1:

Note

AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID1 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xE24	PMCEID1

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.6 PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range `0x4000` to `0x401F`.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D7-2693.

Configurations

External register PMCEID2[31:0] is architecturally mapped to AArch64 System register PMCEID0_EL0[63:32].

External register PMCEID2[63:32] is architecturally mapped to AArch32 System register PMCEID2[31:0].

PMCEID2 is in the Core power domain.

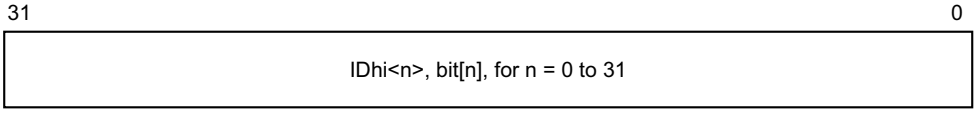
This register is present only when ARMv8.1-PMU is implemented. Otherwise, direct accesses to PMCEID2 are RES0.

Attributes

PMCEID2 is a 32-bit register.

Field descriptions

The PMCEID2 bit assignments are:



IDhi<n>, bit [n], for n = 0 to 31

IDhi[n] corresponds to common event (`0x4000` + n).

For each bit:

`0b0` The common event is not implemented, or not counted.

`0b1` The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMCEID2:

Note

AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID2 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xE28	PMCEID2

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.7 PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

Purpose

Defines which common architectural events and common microarchitectural events are implemented, or counted, using PMU events in the range `0x4020` to `0x403F`.

When the value of a bit in the register is 1 the corresponding common event is implemented and counted.

Note

Arm recommends that, if a common event is never counted, the value of the corresponding register bit is 0.

For more information about the common events and the use of the PMCEIDn registers see *The PMU event number space and common events* on page D7-2693.

Configurations

External register PMCEID3[31:0] is architecturally mapped to AArch64 System register PMCEID1_EL0[63:32].

External register PMCEID3[63:32] is architecturally mapped to AArch32 System register PMCEID3[31:0].

PMCEID3 is in the Core power domain.

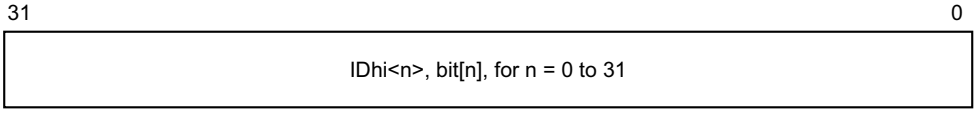
This register is present only when ARMv8.1-PMU is implemented. Otherwise, direct accesses to PMCEID3 are RES0.

Attributes

PMCEID3 is a 32-bit register.

Field descriptions

The PMCEID3 bit assignments are:



IDhi<n>, bit [n], for n = 0 to 31

IDhi[n] corresponds to common event (`0x4020` + n).

For each bit:

`0b0` The common event is not implemented, or not counted.

`0b1` The common event is implemented.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMCEID3:

Note

AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCEID3 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xE2C	PMCEID3

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.8 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

Purpose

Contains PMU-specific configuration data.

Configurations

PMCFGR is in the Core power domain.

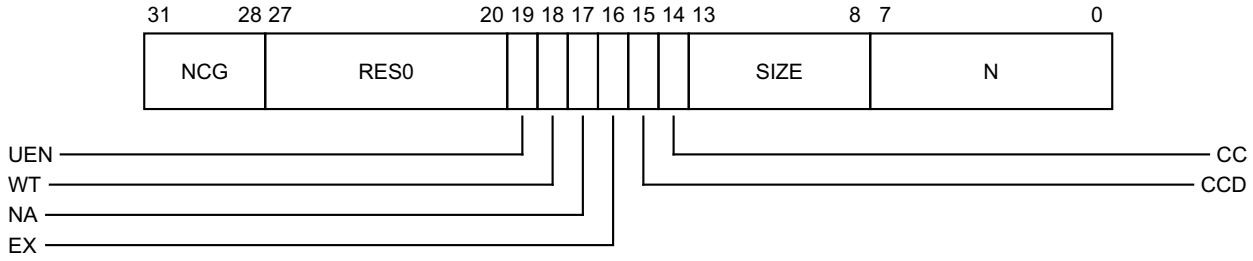
There are no configuration notes.

Attributes

PMCFGR is a 32-bit register.

Field descriptions

The PMCFGR bit assignments are:



NCG, bits [31:28]

This feature is not supported, so this field is RAZ.

Bits [27:20]

Reserved, RES0.

UEN, bit [19]

User-mode Enable Register supported. PMUSERENR_EL0 is not visible in the external debug interface, so this bit is RAZ.

WT, bit [18]

This feature is not supported, so this bit is RAZ.

NA, bit [17]

This feature is not supported, so this bit is RAZ.

EX, bit [16]

Export supported. Value is IMPLEMENTATION DEFINED.

`0b0` PMCR_EL0.X is RES0.

`0b1` PMCR_EL0.X is read/write.

CCD, bit [15]

Cycle counter has prescale. This is RES1 if AArch32 is supported at any EL, and RAZ otherwise.

`0b0` PMCR_EL0.D is RES0.

`0b1` PMCR_EL0.D is read/write.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CC, bit [14]

Dedicated cycle counter (counter 31) supported. This bit is RAO.

SIZE, bits [13:8]

Size of counters, minus one. This field defines the size of the largest counter implemented by the Performance Monitors Unit.

From Armv8, the largest counter is 64-bits, so the value of this field is `0b111111`.

This field is used by software to determine the spacing of the counters in the memory-map. From Armv8, the counters are a doubleword-aligned addresses.

N, bits [7:0]

Number of counters implemented in addition to the cycle counter, PMCCNTR_EL0. The maximum number of event counters is 31.

`0x00` Only PMCCNTR_EL0 implemented.

`0x01` PMCCNTR_EL0 plus one event counter implemented.

and so on up to `0b00011111`, which indicates PMCCNTR_EL0 and 31 event counters implemented.

Accessing the PMCFGR:

Note

AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCFGR can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xE00`	PMCFGR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and AllowExternalPMUAccess() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.9 PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether PMCIDR0 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

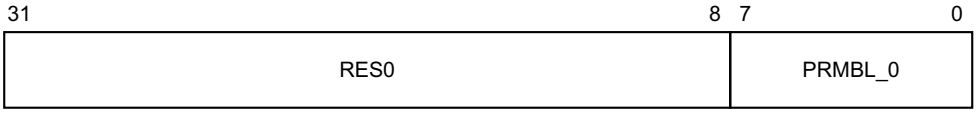
This register is required for CoreSight compliance.

Attributes

PMCIDR0 is a 32-bit register.

Field descriptions

The PMCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the PMCIDR0:

PMCIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFF0`	PMCIDR0

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.10 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether PMCIDR1 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

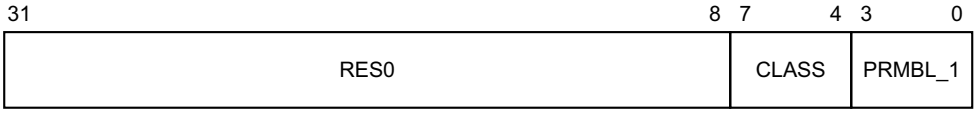
This register is required for CoreSight compliance.

Attributes

PMCIDR1 is a 32-bit register.

Field descriptions

The PMCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the PMCIDR1:

PMCIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xFF4	PMCIDR1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.11 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether PMCIDR2 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

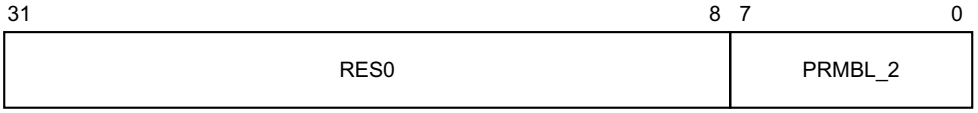
This register is required for CoreSight compliance.

Attributes

PMCIDR2 is a 32-bit register.

Field descriptions

The PMCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the PMCIDR2:

PMCIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFF8`	PMCIDR2

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.12 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Component Identification scheme* on page K2-7663.

Configurations

It is IMPLEMENTATION DEFINED whether PMCIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

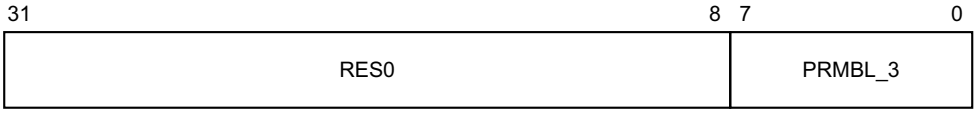
This register is required for CoreSight compliance.

Attributes

PMCIDR3 is a 32-bit register.

Field descriptions

The PMCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the PMCIDR3:

PMCIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFFC`	PMCIDR3

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.13 PMCID1SR, CONTEXTIDR_EL1 Sample Register

The PMCID1SR characteristics are:

Purpose

Contains the sampled value of CONTEXTIDR_EL1, captured on reading PMPCSR[31:0].

Configurations

PMCID1SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only when ARMv8.2-PCSample is implemented. Otherwise, direct accesses to PMCID1SR are RES0.

Note

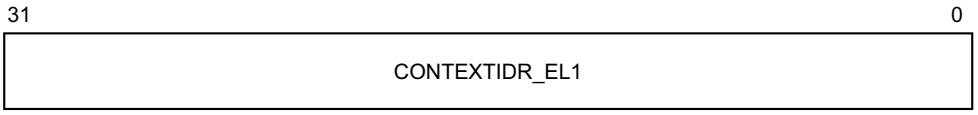
Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

Attributes

PMCID1SR is a 32-bit register.

Field descriptions

The PMCID1SR bit assignments are:



CONTEXTIDR_EL1, bits [31:0]

Context ID. The value of CONTEXTIDR that is associated with the most recent PMPCSR sample.

- If EL1 is using AArch64, then the Context ID is sampled from CONTEXTIDR_EL1.
- If EL1 is using AArch32, then the Context ID is sampled from CONTEXTIDR.
- If EL3 is implemented and is using AArch32, then CONTEXTIDR is a banked register and PMCID1SR samples the current banked copy of CONTEXTIDR for the Security state that is associated with the most recent PMPCSR sample.

Because the value written to PMCID1SR is an indirect read of CONTEXTIDR, therefore it is CONSTRAINED UNPREDICTABLE whether PMCID1SR is set to the original or new value if a read of PMPCSR samples:

- An instruction that writes to CONTEXTIDR_EL1.
- The next Context synchronization event.
- Any instruction executed between these two instructions.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMCID1SR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCID1SR can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0x208	PMCID1SR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

PMCID1SR can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0x228	PMCID1SR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.14 PMCID2SR, CONTEXTIDR_EL2 Sample Register

The PMCID2SR characteristics are:

Purpose

Contains the sampled value of CONTEXTIDR_EL2, captured on reading PMPCSR[31:0].

Configurations

PMCID2SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only when ARMv8.2-PCSample is implemented. Otherwise, direct accesses to PMCID2SR are RES0.

Note

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

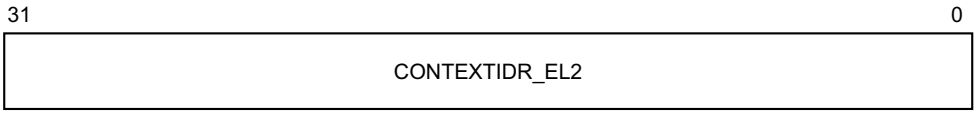
If EL2 is not implemented, this register is RES0.

Attributes

PMCID2SR is a 32-bit register.

Field descriptions

The PMCID2SR bit assignments are:



CONTEXTIDR_EL2, bits [31:0]

Context ID. The value of CONTEXTIDR that is associated with the most recent PMPCSR sample.

- If EL2 is using AArch64, then the Context ID sampled from CONTEXTIDR_EL2.
- If EL2 is using AArch32, then this field is set to an UNKNOWN value.

Because the value written to PMCID2SR is an indirect read of CONTEXTIDR, therefore it is CONSTRAINED UNPREDICTABLE whether PMCID2SR is set to the original or new value if a read of PMPCSR samples:

- An instruction that writes to CONTEXTIDR_EL2.
- The next Context synchronization event.
- Any instruction executed between these two instructions.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMCID2SR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCID2SR can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0x22C	PMCID2SR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.15 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

Configurations

External register PMCNTENCLR_EL0[31:0] is architecturally mapped to AArch64 System register PMCNTENCLR_EL0[31:0].

External register PMCNTENCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENCLR[31:0].

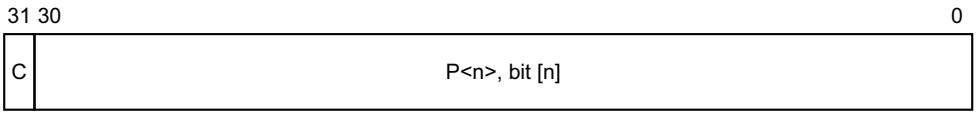
PMCNTENCLR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMCNTENCLR_EL0 is a 32-bit register.

Field descriptions

The PMCNTENCLR_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:

`0b0` When read, means the cycle counter is disabled. When written, has no effect.

`0b1` When read, means the cycle counter is enabled. When written, disables the cycle counter.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter disable bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

`0b0` When read, means that PMEVCNTR<n>_EL0 is disabled. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n>_EL0 is enabled. When written, disables PMEVCNTR<n>_EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMCNTENCLR_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCNTENCLR_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xC20	PMCNTENCLR_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.16 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<n>. Reading this register shows which counters are enabled.

Configurations

External register PMCNTENSET_EL0[31:0] is architecturally mapped to AArch64 System register PMCNTENSET_EL0[31:0].

External register PMCNTENSET_EL0[31:0] is architecturally mapped to AArch32 System register PMCNTENSET[31:0].

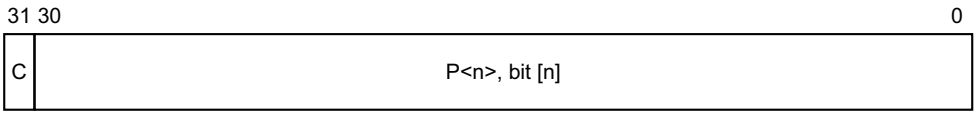
PMCNTENSET_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMCNTENSET_EL0 is a 32-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

`0b0` When read, means the cycle counter is disabled. When written, has no effect.

`0b1` When read, means the cycle counter is enabled. When written, enables the cycle counter.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter enable bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

`0b0` When read, means that PMEVCNTR<n>_EL0 is disabled. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n>_EL0 event counter is enabled. When written, enables PMEVCNTR<n>_EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMCNTENSET_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCNTENSET_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xC00	PMCNTENSET_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.17 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Configurations

External register PMCR_EL0[7:0] is architecturally mapped to AArch32 System register PMCR[7:0].

External register PMCR_EL0[7:0] is architecturally mapped to AArch64 System register PMCR_EL0[7:0].

PMCR_EL0 is in the Core power domain. Some or all RW fields of this register have defined reset values. The field descriptions identify when the reset values apply.

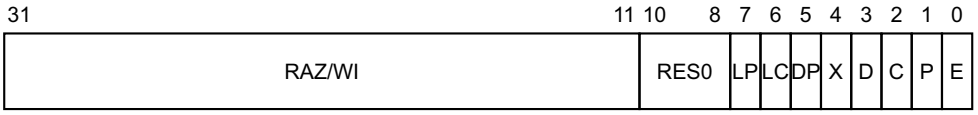
This register is only partially mapped to the internal PMCR System register. An external agent must use other means to discover the information held in PMCR[31:11], such as accessing PMCFGR and the ID registers.

Attributes

PMCR_EL0 is a 32-bit register.

Field descriptions

The PMCR_EL0 bit assignments are:



Bits [31:11]

Reserved, RAZ/WI.

Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

Bits [10:8]

Reserved, RES0.

LP, bit [7]

When ARMv8.5-PMU is implemented:

Long event counter enable. Determines when unsigned overflow is recorded by a counter overflow bit.

`0b0` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>_EL0[31:0].

`0b1` Event counter overflow on increment that causes unsigned overflow of PMEVCNTR<n>_EL0[63:0].

If EL2 is implemented and MDCR_EL2.HPMN or HDCR.HPMN is less than PMCR_EL0.N, this bit does not affect the operation of event counters in the range [HDCR.HPMN..(PMCR_EL0.N-1)] or [MDCR_EL2.HPMN:(PMCR_EL0.N-1)].

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

If the highest implemented Exception level is using AArch32, it is IMPLEMENTATION DEFINED whether this bit is RW or RAZ/WI.

Otherwise:

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines when unsigned overflow is recorded by the cycle counter overflow bit.

`0b0` Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[31:0].

`0b1` Cycle counter overflow on increment that causes unsigned overflow of PMCCNTR_EL0[63:0].

Arm deprecates use of PMCR_EL0.LC = 0.

In an AArch64 only implementation, this field is RES1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

`0b0` Cycle counting by PMCCNTR_EL0 is not affected by this bit.

`0b1` When event counting for counters in the range [0..(MDCR_EL2.HPMN-1)] is prohibited, cycle counting by PMCCNTR_EL0 is disabled.

For more information about the interaction between the Performance Monitors and EL3, see *Effect of EL3 and EL2* on page D7-2679.

When EL3 is not implemented, this field is RES0:

- When ARMv8.1-PMU is not implemented.
- When ARMv8.1-PMU is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

`0b0` Do not export events.

`0b1` Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL PE trace unit. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

D, bit [3]

Clock divider. The possible values of this bit are:

`0b0` When enabled, PMCCNTR_EL0 counts every clock cycle.

`0b1` When enabled, PMCCNTR_EL0 counts once every 64 clock cycles.

In an AArch64 only implementation this field is RES0, otherwise it is an RW field. If PMCR_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

Arm deprecates use of PMCR_EL0.D = 1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

`0b0` No action.

`0b1` Reset PMCCNTR_EL0 to zero.

This bit is always RAZ.

Note

Resetting PMCCNTR_EL0 does not change the cycle counter overflow bit.

The value of PMCR_EL0.LC is ignored, and bits [63:0] of all affected events are reset.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

`0b0` No action.

`0b1` Reset all event counters, not including PMCCNTR_EL0, to zero.

This bit is always RAZ.

Note

Resetting the event counters does not change the event counter overflow bits.

If ARMv8.5-PMU is implemented, the values of MDCR_EL2.HLP, and PMCR_EL0.LP are ignored and bits [63:0] of all event counters are reset.

E, bit [0]

Enable.

`0b0` All event counters in the range [0..(PMN-1)] and PMCCNTR_EL0, are disabled.

`0b1` All event counters in the range [0..(PMN-1)] and PMCCNTR_EL0, are enabled by PMCNTENSET_EL0.

This bit is RW.

If EL2 is implemented then:

- If EL2 is using AArch32, PMN is HDCR.HPMN.
- If EL2 is using AArch64, PMN is MDCR_EL2.HPMN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If PMN is less than PMCR_EL0.N, this bit does not affect the operation of event counters in the range [PMN..(PMCR_EL0.N-1)].

If EL2 is not implemented, PMN is PMCR_EL0.N.

Note

The effect of MDCR_EL2.HPMN or HDCR.HPMN on the operation of this bit always applies if EL2 is implemented, at all Exception levels including EL2 and EL3, and regardless of whether EL2 is enabled in the current Security state. For more information, see the description of MDCR_EL2.HPMN or HDCR.HPMN.

On a Warm reset, this field resets to `0`.

Accessing the PMCR_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMCR_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xE04`	PMCR_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.18 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Configurations

It is IMPLEMENTATION DEFINED whether PMDEVAFF0 is implemented in the Core power domain or in the Debug power domain.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

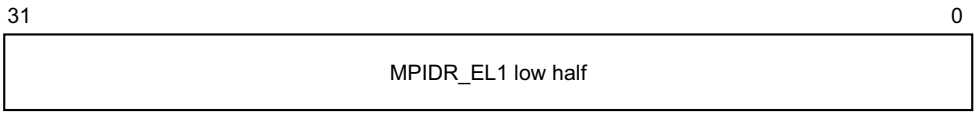
This register is required if the external interface to the PMU is implemented.

Attributes

PMDEVAFF0 is a 32-bit register.

Field descriptions

The PMDEVAFF0 bit assignments are:



MPIDR_EL1 low half, bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the PMDEVAFF0:

PMDEVAFF0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xFA8	PMDEVAFF0

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.19 PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Configurations

It is IMPLEMENTATION DEFINED whether PMDEVAFF1 is implemented in the Core power domain or in the Debug power domain.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

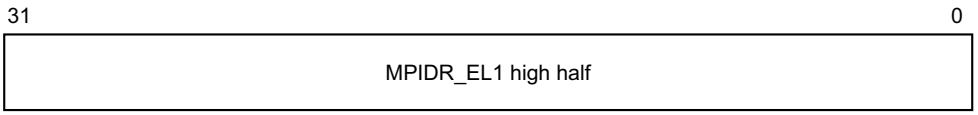
This register is required if the external interface to the PMU is implemented.

Attributes

PMDEVAFF1 is a 32-bit register.

Field descriptions

The PMDEVAFF1 bit assignments are:



MPIDR_EL1 high half, bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the PMDEVAFF1:

PMDEVAFF1 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xFAC	PMDEVAFF1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.20 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the Performance Monitor component.

Configurations

It is IMPLEMENTATION DEFINED whether PMDEVARCH is implemented in the Core power domain or in the Debug power domain.

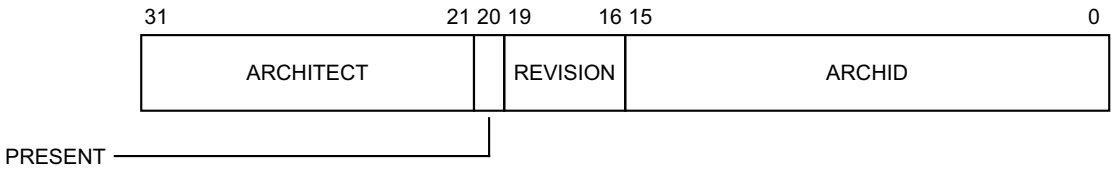
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

PMDEVARCH is a 32-bit register.

Field descriptions

The PMDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For Performance Monitors, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, `0x4`.

Bits [27:21] are the JEP106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in Armv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

For Performance Monitors, the revision defined by Armv8 is `0x0`.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an Armv8 debug component. For architectures defined by Arm this is further subdivided.

For Performance Monitors:

- Bits [15:12] are the architecture version, `0x2`.
- Bits [11:0] are the architecture part number, `0xA16`.

This corresponds to Performance Monitors architecture version PMUv3.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The PMUv3 memory-mapped programmers' model can be used by devices other than Armv8 processors. Software must determine whether the PMU is attached to an Armv8 processor by using the PMDEVAFF0 and PMDEVAFF1 registers to discover the affinity of the PMU to any Armv8 processors.

Accessing the PMDEVARCH:

PMDEVARCH can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xFBC	PMDEVARCH

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.21 PMDEVID, Performance Monitors Device ID register

The PMDEVID characteristics are:

Purpose

Provides information about features of the Performance Monitors implementation.

Configurations

It is IMPLEMENTATION DEFINED whether PMDEVID is implemented in the Core power domain or in the Debug power domain.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

This register is required from Armv8.2 and in any implementation that includes ARMv8.2-PCSample. Otherwise, its location is RES0.

Note

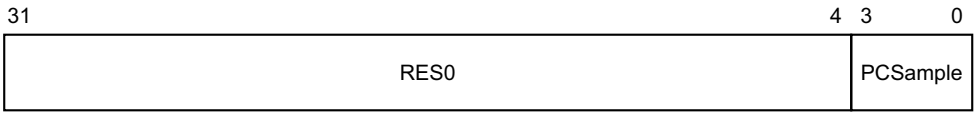
Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

Attributes

PMDEVID is a 32-bit register.

Field descriptions

The PMDEVID bit assignments are:



Bits [31:4]

Reserved, RES0.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using Performance Monitors registers. Permitted values of this field are:

`0b0000` PC Sample-based Profiling Extension is not implemented in the Performance Monitors register space.

`0b0001` PC Sample-based Profiling Extension is implemented in the Performance Monitors register space.

All other values are reserved.

ARMv8.2-PCSample implements the functionality identified by the value `0b0001`.

Accessing the PMDEVID:

PMDEVID can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFC8`	PMDEVID

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.22 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PEs performance monitor interface.

Configurations

It is IMPLEMENTATION DEFINED whether PMDEVTYPE is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

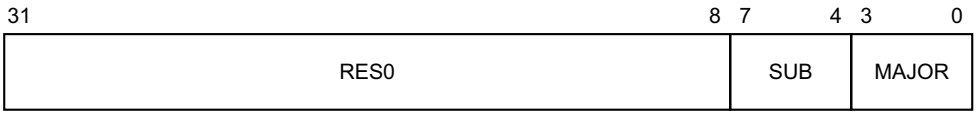
If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Attributes

PMDEVTYPE is a 32-bit register.

Field descriptions

The PMDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as `0x6` to indicate this is a performance monitor component.

Accessing the PMDEVTYPE:

PMDEVTYPE can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFCC`	PMDEVTYPE

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.23 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configurations

External register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to AArch64 System register PMEVCNTR<n>_EL0[31:0].

External register PMEVCNTR<n>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVCNTR<n>[31:0].

PMEVCNTR<n>_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. The field descriptions identify when the reset values apply.

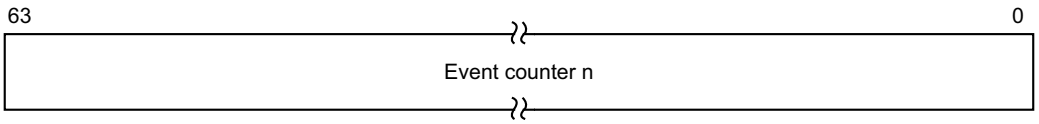
Attributes

PMEVCNTR<n>_EL0 is a 64-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:

When ARMv8.5-PMU is implemented:



Bits [63:0]

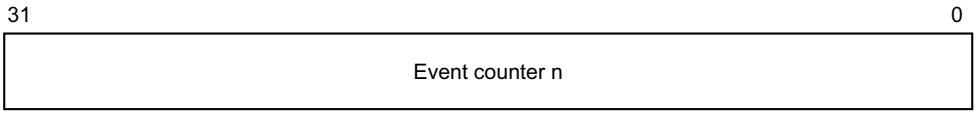
Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

If the highest implemented Exception level is using AArch32, the optional external interface to the performance monitors is implemented, and the PMCR.LP and HDCR.HLP bits are RAZ/WI, then locations in the external interface to the performance monitors that map to PMEVCNTR<n>_EL0[63:32] return UNKNOWN values on reads.

If the implementation does not support AArch64 at any Exception level, bits [63:32] of the event counters are not required to be implemented.

This field resets to an architecturally UNKNOWN value.

Otherwise:



Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMEVCNTR<n>_EL0:

External accesses to the performance monitors ignore PMUSERENR_EL0 and, if implemented, MDCR_EL2.{TPM, TPMCR, HPMN} and MDCR_EL3.TPM. This means that all counters are accessible regardless of the current Exception level or privilege of the access.

If ARMv8.5-PMUis not implemented, when IsCorePowered(), DoubleLockStatus(), OSLockStatus() or !AllowExternalPMUAccess(), 32-bit access to `0x004`+8n has a CONSTRAINED UNPREDICTABLE behavior.

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMEVCNTR<n>_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0x000` + 8n	PMEVCNTR<n>_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Non-Confidential

I5.3.24 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configurations

External register PMEVTYPER<n>_EL0[31:0] is architecturally mapped to AArch64 System register PMEVTYPER<n>_EL0[31:0].

External register PMEVTYPER<n>_EL0[31:0] is architecturally mapped to AArch32 System register PMEVTYPER<n>[31:0].

PMEVTYPER<n>_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

If event counter n is not implemented then accesses to this register are:

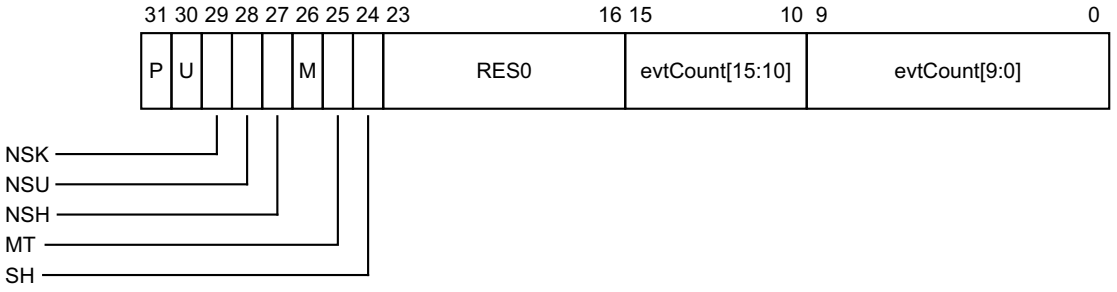
- RES0 when IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalPMUAccess().
- A CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR otherwise.

Attributes

PMEVTYPER<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVTYPER<n>_EL0 bit assignments are:



P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the PMEVTYPER<n>_EL0.NSK bit. The possible values of this bit are:

`0b0` Count events in EL1.

`0b1` Do not count events in EL1.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the PMEVTYPER<n>_EL0.NSU bit. The possible values of this bit are:

`0b0` Count events in EL0.

`0b1` Do not count events in EL0.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.P bit, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.U bit, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

NSH, bit [27]

EL2 (Hypervisor) filtering bit. Controls counting in EL2. If EL2 is not implemented, this bit is RES0. If Secure EL2 is implemented, counting in Secure EL2 is further controlled by the PMEVTYPER<n>_EL0.SH bit.

`0b0` Do not count events in EL2.

`0b1` Count events in EL2.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of the PMEVTYPER<n>_EL0.P bit, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to `0b0`.

Note

This field is not visible in the AArch32 PMEVTYPER<n> System register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

`0b0` Count events only on controlling PE.

`0b1` Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

Note

- When the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach, an implementation is described as multi-threaded. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of the MPIDR_EL1.MT bit, when read at the highest implemented Exception level, is `0b1`.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SH, bit [24]

When ARMv8.4-SecEL2 is implemented:

Secure EL2 filtering.

If the value of this bit is not equal to the value of the PMEVTYPER<n>_EL0.NSH bit, events in Secure EL2 are counted.

Otherwise, events in Secure EL2 are not counted.

If Secure EL2 is not implemented or is disabled, this field is RES0.

Note

This field is not visible in the AArch32 PMEVTYPER<n> System register.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [23:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

When ARMv8.1-PMU is implemented:

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>_EL0.

Software must program this field with an event that is supported by the PE being programmed.

There are three types of event:

- Common architectural and microarchitectural events.
- Arm recommended common architectural and microarchitectural events.
- IMPLEMENTATION DEFINED events.

The ranges of event numbers allocated to each type of event are shown in Table D7-6 on page D7-2693.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range `0x000` to `0x03F`, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

Arm recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Non-Confidential

Accessing the PMEVTYPER<n>_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMEVTYPER<n>_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0x400 + 4n	PMEVTYPER<n>_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

I5.3.25 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

Configurations

External register PMINTENCLR_EL1[31:0] is architecturally mapped to AArch64 System register PMINTENCLR_EL1[31:0].

External register PMINTENCLR_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENCLR[31:0].

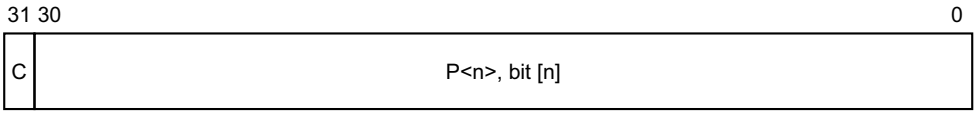
PMINTENCLR_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:

`0b0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`0b1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

`0b0` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is disabled. When written, has no effect.

`0b1` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR<n>_EL0 interrupt request.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMINTENCLR_EL1:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMINTENCLR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xC60	PMINTENCLR_EL1

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

I5.3.26 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

Configurations

External register PMINTENSET_EL1[31:0] is architecturally mapped to AArch64 System register PMINTENSET_EL1[31:0].

External register PMINTENSET_EL1[31:0] is architecturally mapped to AArch32 System register PMINTENSET[31:0].

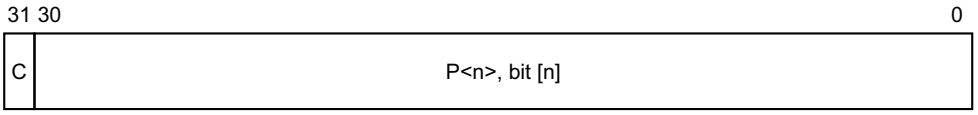
PMINTENSET_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMINTENSET_EL1 is a 32-bit register.

Field descriptions

The PMINTENSET_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:

`0b0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`0b1` When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

`0b0` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is disabled. When written, has no effect.

`0b1` When read, means that the PMEVCNTR<n>_EL0 event counter interrupt request is enabled. When written, enables the PMEVCNTR<n>_EL0 interrupt request.

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing the PMINTENSET_EL1:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMINTENSET_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xC40	PMINTENSET_EL1

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

I5.3.27 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configurations

It is IMPLEMENTATION DEFINED whether PMITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

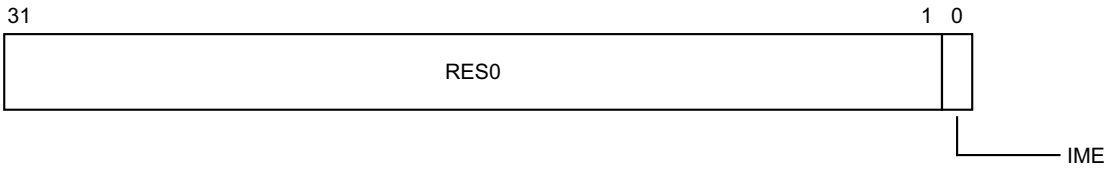
Implementation of this register is OPTIONAL.

Attributes

PMITCTRL is a 32-bit register.

Field descriptions

The PMITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0b0` Normal operation.

`0b1` Integration mode enabled.

On a Implementation reset, this field resets to `0`.

Accessing the PMITCTRL:

PMITCTRL can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xF00`	PMITCTRL

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register are IMPDEF.

I5.3.28 PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

Purpose

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Configurations

It is IMPLEMENTATION DEFINED whether PMLAR is implemented in the Core power domain or in the Debug power domain.

If AMRMv8.4-Debug is implemented, the Software Lock is not implemented.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

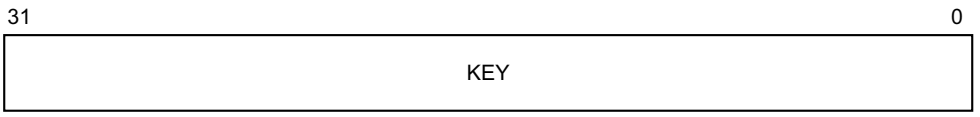
Attributes

PMLAR is a 32-bit register.

Field descriptions

The PMLAR bit assignments are:

When the Software Lock is implemented:

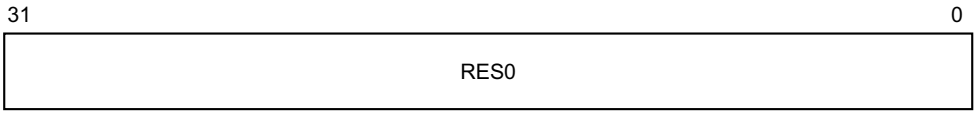


KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Otherwise:



Bits [31:0]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMLAR:

PMLAR can be accessed through its memory-mapped interface:

Component	Offset	Instance
PMU	0xFB0	PMLAR

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are WO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.29 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

Purpose

Indicates the current status of the software lock for Performance Monitors registers.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Configurations

It is IMPLEMENTATION DEFINED whether PMLSR is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

If ARMv8.4-Debug is implemented, the Software Lock is not implemented.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

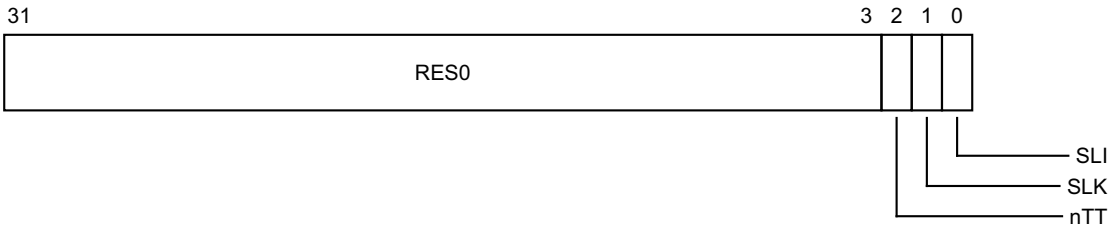
Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

Attributes

PMLSR is a 32-bit register.

Field descriptions

The PMLSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

When the Software Lock is implemented:

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

`0b0` Lock clear. Writes are permitted to this component's registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

The following resets apply:

- If Armv8.3-DoPD is implemented, this register is reset by Cold reset and not affected by External debug reset. If Armv8.3-DoPD is not implemented, this register is reset by External debug reset and not affected by Cold reset.
- On a reset, this field resets to 1.

Otherwise:

Reserved, RAZ.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

0b0 Software Lock not implemented or not memory-mapped access.

0b1 Software Lock implemented and memory-mapped access.

Accessing the PMLSR:

PMLSR can be accessed through its memory-mapped interface:

Component	Offset	Instance
PMU	0xFB4	PMLSR

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.30 PMMIR, Performance Monitors Machine Identification Register

The PMMIR characteristics are:

Purpose

Describes Performance Monitors parameters specific to the implementation.

Configurations

PMMIR is in the Core power domain.

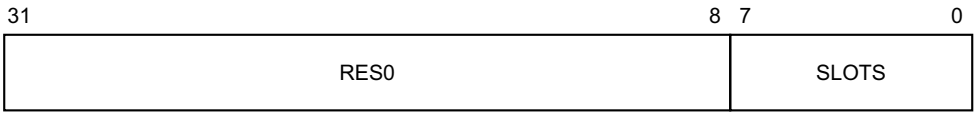
This register is present only when ARMv8.4-PMU is implemented. Otherwise, direct accesses to PMMIR are RES0.

Attributes

PMMIR is a 32-bit register.

Field descriptions

The PMMIR bit assignments are:



Bits [31:8]

Reserved, RES0.

SLOTS, bits [7:0]

Operation width. The largest value by which the STALL_SLOT event might increment by in a single cycle. If the STALL_SLOT event is implemented, this field must not be zero.

Accessing the PMMIR:

If the Core power domain is off or in a low-power state, access on this interface returns an Error.

PMMIR can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xE40	PMMIR

This interface is accessible as follows:

- When !IsCorePowered(), or DoubleLockStatus(), or OSLockStatus() or !AllowExternalPMUAccess() accesses to this register generate an error response.
- Otherwise accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.31 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSCLR_EL0 characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>. Writing to this register clears these bits.

Configurations

External register PMOVSCLR_EL0[31:0] is architecturally mapped to AArch64 System register PMOVSCLR_EL0[31:0].

External register PMOVSCLR_EL0[31:0] is architecturally mapped to AArch32 System register PMOVSR[31:0].

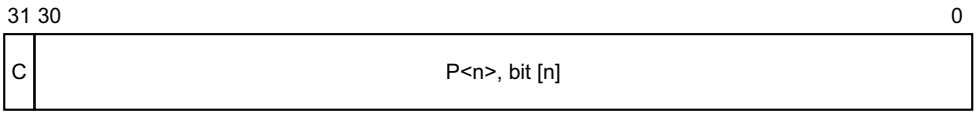
PMOVSCLR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMOVSCLR_EL0 is a 32-bit register.

Field descriptions

The PMOVSCLR_EL0 bit assignments are:



C, bit [31]

Cycle counter overflow clear bit.

`0b0` When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means the cycle counter has overflowed since this bit was last cleared. When written, clears the cycle counter overflow bit to 0.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow clear bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

`0b0` When read, means that PMEVCNTR<n>_EL0 has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n>_EL0 has overflowed since this bit was last cleared. When written, clears the PMEVCNTR<n>_EL0 overflow bit to 0.

If ARMv8.5-PMU is implemented, MDCR_EL2.HLP and PMCR_EL0.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR<n>_EL0[31:0] or unsigned overflow of PMEVCNTR<n>_EL0[63:0].

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMOVSCLR_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMOVSCLR_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xC80	PMOVSCLR_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.32 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<n>.

Configurations

External register PMOVSSET_EL0[31:0] is architecturally mapped to AArch64 System register PMOVSSET_EL0[31:0].

External register PMOVSSET_EL0[31:0] is architecturally mapped to AArch32 System register PMOVSSET[31:0].

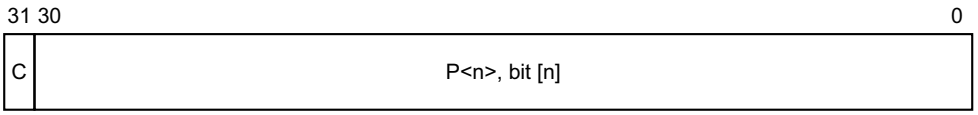
PMOVSSET_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMOVSSET_EL0 is a 32-bit register.

Field descriptions

The PMOVSSET_EL0 bit assignments are:



C, bit [31]

Cycle counter overflow set bit.

`0b0` When read, means the cycle counter has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means the cycle counter has overflowed since this bit was last cleared. When written, sets the cycle counter overflow bit to 1.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

On a Warm reset, this field resets to an architecturally UNKNOWN value.

P<n>, bit [n], for n = 0 to 30

Event counter overflow set bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are RAZ/WI.

`0b0` When read, means that PMEVCNTR<n>_EL0 has not overflowed since this bit was last cleared. When written, has no effect.

`0b1` When read, means that PMEVCNTR<n>_EL0 has overflowed since this bit was last cleared. When written, sets the PMEVCNTR<n>_EL0 overflow bit to 1.

If ARMv8.5-PMU is implemented, MDCR_EL2.HLP and PMCR_EL0.LP control whether an overflow is detected from unsigned overflow of PMEVCNTR<n>_EL0[31:0] or unsigned overflow of PMEVCNTR<n>_EL0[63:0].

On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMOVSSET_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

PMOVSSET_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xCC0	PMOVSSET_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are RO.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are RW.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.33 PMPCSR, Program Counter Sample Register

The PMPCSR characteristics are:

Purpose

Holds a sampled instruction address value.

Configurations

PMPCSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only when ARMv8.2-PCSample is implemented. Otherwise, direct accesses to PMPCSR are RES0.

Note

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

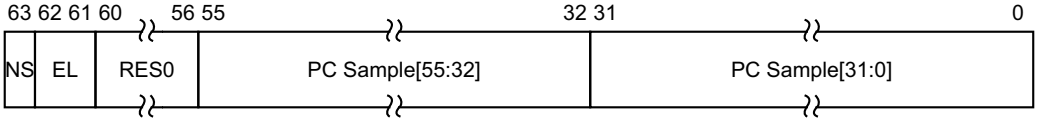
Support for 64-bit atomic reads is IMPLEMENTATION DEFINED. If 64-bit atomic reads are implemented, a 64-bit read of PMPCSR has the same side-effect as a 32-bit read of PMCSR[31:0] followed by a 32-bit read of PMPCSR[63:32], returning the combined value. For example, if the PE is in Debug state then a 64-bit atomic read returns bits[31:0] == `0xFFFFFFFF` and bits[63:32] UNKNOWN.

Attributes

PMPCSR is a 64-bit register.

Field descriptions

The PMPCSR bit assignments are:



NS, bit [63]

Non-secure state sample. Indicates the Security state that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

EL, bits [62:61]

Exception level status sample. Indicates the Exception level that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

`0b00` Sample is from EL0.

`0b01` Sample is from EL1.

`0b10` Sample is from EL2.

`0b11` Sample is from EL3.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [60:56]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PC Sample[55:32], bits [55:32]

Bits[55:32] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PC Sample[31:0], bits [31:0]

Bits[31:0] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

For a read of PMPCSR[31:0] from the memory-mapped interface, if PMLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.

In any other cases, a read of PMPCSR[31:0] has the side-effect of indirectly writing to PMPCSR[63:32], PMCID1SR, PMCID2SR, and PMVIDSR:

- If the PE is in Debug state, or PC Sample-based profiling is prohibited, PMPCSR[31:0] reads as `0xFFFFFFFF`, and PMPCSR[63:32], PMCID1SR, PMCID2SR, and PMVIDSR become UNKNOWN.
- If the PE is in Reset state, the sampled value is UNKNOWN and PMPCSR[63:32], PMCID1SR, PMCID2SR, and PMVIDSR become UNKNOWN.
- If no instruction has been sampled since the PE left Reset state, Debug state, or a state where PC Sample-based Profiling is prohibited, the sampled value is `0xFFFFFFFF`, and PMPCSR.[63:32], PMCID1SR, PMCID2SR, and PMVIDSR become UNKNOWN. Any subsequent read will return an instruction address value.

Accessing the PMPCSR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824

PMPCSR[31:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
PMU	`0x200`	PMPCSR	31:0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to PMPCSR[31:0] are RO.
- Otherwise accesses to PMPCSR[31:0] generate an error response.

PMPCSR[31:0] can be accessed through the external debug interface:

Component	Offset	Instance	Range
PMU	`0x220`	PMPCSR	31:0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to PMPCSR[31:0] are RO.
- Otherwise accesses to PMPCSR[31:0] generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMPCSR[63:32] can be accessed through the external debug interface:

Component	Offset	Instance	Range
PMU	0x204	PMPCSR	63:32

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to PMPCSR[63:32] are RO.
- Otherwise accesses to PMPCSR[63:32] generate an error response.

PMPCSR[63:32] can be accessed through the external debug interface:

Component	Offset	Instance	Range
PMU	0x224	PMPCSR	63:32

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to PMPCSR[63:32] are RO.
- Otherwise accesses to PMPCSR[63:32] generate an error response.

I5.3.34 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether PMPIDR0 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

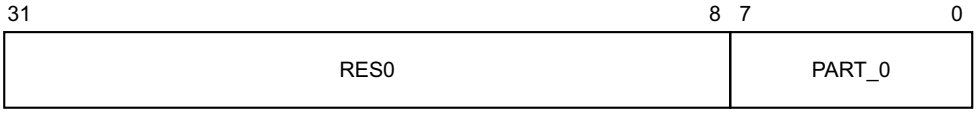
This register is required for CoreSight compliance.

Attributes

PMPIDR0 is a 32-bit register.

Field descriptions

The PMPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the PMPIDR0:

PMPIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xFE0	PMPIDR0

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.35 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether PMPIDR1 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

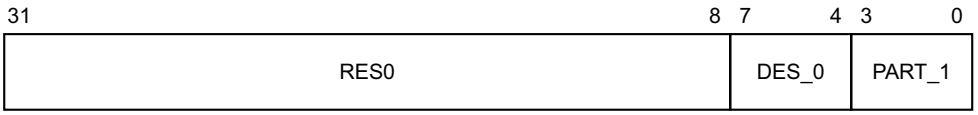
This register is required for CoreSight compliance.

Attributes

PMPIDR1 is a 32-bit register.

Field descriptions

The PMPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the PMPIDR1:

PMPIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFE4`	PMPIDR1

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.36 PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether PMPIDR2 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

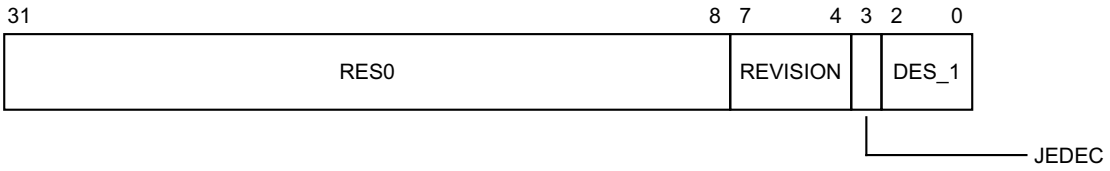
This register is required for CoreSight compliance.

Attributes

PMPIDR2 is a 32-bit register.

Field descriptions

The PMPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is `0b011`.

Accessing the PMPIDR2:

PMPIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFE8`	PMPIDR2

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.37 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether PMPIDR3 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

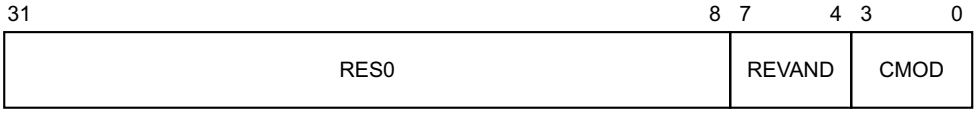
This register is required for CoreSight compliance.

Attributes

PMPIDR3 is a 32-bit register.

Field descriptions

The PMPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using PMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the PMPIDR3:

PMPIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xFEC	PMPIDR3

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.38 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see *About the Peripheral identification scheme* on page K2-7661.

Configurations

It is IMPLEMENTATION DEFINED whether PMPIDR4 is implemented in the Core power domain or in the Debug power domain.

Implementation of this register is OPTIONAL.

If ARMv8.3-DoPD is implemented, this register is in the Core power domain. If ARMv8.3-DoPD is not implemented, this register is in the Debug power domain.

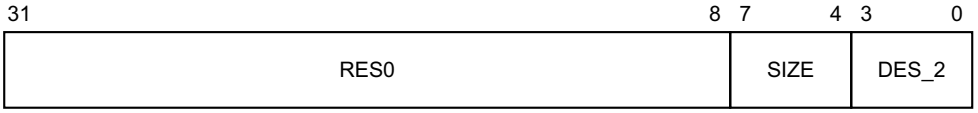
This register is required for CoreSight compliance.

Attributes

PMPIDR4 is a 32-bit register.

Field descriptions

The PMPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For Arm Limited, this field is `0b0100`.

Accessing the PMPIDR4:

PMPIDR4 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	`0xFD0`	PMPIDR4

This interface is accessible as follows:

- When ARMv8.3-DoPD is not implemented or IsCorePowered() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.39 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`. For more information, see SW_INCR.

Configurations

External register PMSWINC_EL0[31:0] is architecturally mapped to AArch64 System register PMSWINC_EL0[31:0].

External register PMSWINC_EL0[31:0] is architecturally mapped to AArch32 System register PMSWINC[31:0].

PMSWINC_EL0 is in the Core power domain.

Implementation of this register is OPTIONAL.

If this register is implemented, use of it is deprecated.

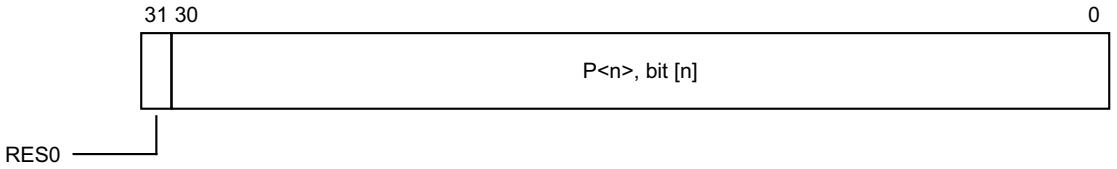
If 1 is written to bit [n] from the external debug interface, it is CONSTRAINED UNPREDICTABLE whether or not a SW_INCR event is created for counter n. This is consistent with not implementing the register in the external debug interface.

Attributes

PMSWINC_EL0 is a 32-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:



Bit [31]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 30

Event counter software increment bit for PMEVCNTR<n>_EL0.

If PMCFGR.N is less than 31, bits [30:PMCFGR.N] are WI.

`0b0` No action. The write to this bit is ignored.

`0b1` It is CONSTRAINED UNPREDICTABLE whether a SW_INCR event is generated for event counter n.

Accessing the PMSWINC_EL0:

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalPMUAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMSWINC_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0xCA0	PMSWINC_EL0

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and SoftwareLockStatus() accesses to this register are WI.
- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalPMUAccess() and !SoftwareLockStatus() accesses to this register are WO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.3.40 PMVIDSR, VMID Sample Register

The PMVIDSR characteristics are:

Purpose

Contains the sampled VMID value that is captured on reading PMPCSR[31:0].

Configurations

PMVIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

This register is present only when ARMv8.2-PCSample is implemented. Otherwise, direct accesses to PMVIDSR are RES0.

Note

Before Armv8.2, the PC Sample-based Profiling Extension can be implemented in the external debug register space, as indicated by the value of EDDEVID.PCSample.

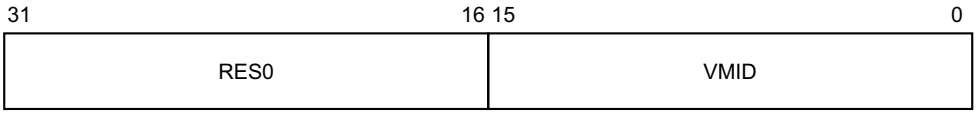
If EL2 is not implemented, this register is RES0.

Attributes

PMVIDSR is a 32-bit register.

Field descriptions

The PMVIDSR bit assignments are:



Bits [31:16]

Reserved, RES0.

VMID, bits [15:0]

VMID sample. The VMID associated with the most recent PMPCSR sample.

- If EL2 is implemented and is using AArch64, then the VMID is held in VTTBR_EL2.VMID.
- If EL2 is implemented and is using AArch32, then the VMID is held in VTTBR.VMID.
- This field is set to an UNKNOWN value if any of the following apply:
  - PMPCSR.NS == 0.
  - PMPCSR.EL == 0b10.
  - PMPCSR.NS == 1, PMPCSR.EL == 0b00, EL2 is using AArch64, HCR_EL2.E2H == 1, and HCR_EL2.TGE == 1.
- If EL2 is not implemented, then this field is RES0.
- If 16-bit VMIDs are not supported, PMVIDSR.VMID[15:8] is RES0.
- If 16-bit VMIDs are supported, but VTTBRx.VMID[15:8] are not used, PMVIDSR.VMID[15:8] is set to RES0.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the PMVIDSR:

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see *Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN* on page H7-6824

PMVIDSR can be accessed through the external debug interface:

Component	Offset	Instance
PMU	0x20C	PMVIDSR

This interface is accessible as follows:

- When IsCorePowered(), !DoubleLockStatus() and !OSLockStatus() accesses to this register are RO.
- Otherwise accesses to this register generate an error response.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.4 External Activity Monitors Extension registers summary

The memory-mapped interface to the Activity Monitors Extension registers provides read-only access to:

- Read-only copies of the Activity Monitors Extension System registers, with the exception of AMUSERENR.
- An implementation identification register, AMIIDR.
- If they are implemented, the OPTIONAL Activity Monitors CoreSight and ID registers.

The locations of the registers are defined as offsets from a base address. The base address of the memory-mapped view must be aligned to a 4KB boundary, but is otherwise IMPLEMENTATION DEFINED. *Activity Monitors external register views* defines this memory map.

I5.4.1 Activity Monitors external register views

Table I5-2 shows the external view of the Activity Monitors registers. All implemented registers are RO. Offsets within the 4KB region not defined in this table are *RAZ/WI*.

Each entry in the Name column links to the register description in *Activity Monitors external register descriptions* on page I5-7115, and:

- If the *System register?* on page I5-7036 column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
  - *Activity Monitors registers* on page D13-3584, for the AArch64 System register.
  - *Activity Monitors registers* on page G8-6542, for the AArch32 System register.
- Otherwise, the register is accessible only using the external memory-mapped interface.

Table I5-2 Activity Monitors external register views

Name	Description	System register?	Offset
AMEVCNTR0<n>[31:0] AMEVCNTR0<n>[63:32]	Activity Monitor Event Counter registers 0	Yes	0x000+8n 0x004+8n
AMEVCNTR1<n>[31:0] AMEVCNTR1<n>[63:32]	Activity Monitor Event Counter registers 1	Yes	0x100+8n 0x104+8n
AMEVTYPER0<n>	Activity Monitor Event Type registers 0	Yes	0x400+4n
AMEVTYPER1<n>	Activity Monitor Event Type registers 1	Yes	0x480+4n
AMCNTENSET0	Activity Monitors Counter Enable Set register 0	Yes	0xC00
AMCNTENSET1	Activity Monitors Counter Enable Set register 1	Yes	0xC04

I5.5 Activity Monitors external register descriptions

This section lists the external Activity Monitors registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.1 AMCFGR, Activity Monitors Configuration Register

The AMCFGR characteristics are:

Purpose

Global configuration register for the activity monitors.

Provides information on supported features, the number of counter groups implemented, the total number of activity monitor event counters implemented, and the size of the counters. AMCFGR is applicable to both the architected and the auxiliary counter groups.

Configurations

External register AMCFGR[31:0] is architecturally mapped to AArch64 System register AMCFGR_EL0[31:0].

External register AMCFGR[31:0] is architecturally mapped to AArch32 System register AMCFGR[31:0].

The power domain of AMCFGR is IMPLEMENTATION DEFINED.

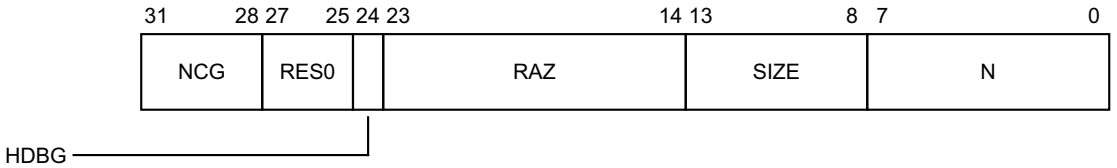
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCFGR are RES0.

Attributes

AMCFGR is a 32-bit register.

Field descriptions

The AMCFGR bit assignments are:



NCG, bits [31:28]

Defines the number of counter groups.

The number of implemented counter groups is defined as [AMCFGR.NCG + 1].

If the number of implemented auxiliary activity monitor event counters is zero, this field has a value of `0b0000`. Otherwise, this field has a value of `0b0001`.

Bits [27:25]

Reserved, RES0.

HDBG, bit [24]

Halt-on-debug supported.

From Armv8, this feature must be supported, and so this bit is `0b1`.

`0b0` AMCR.HDBG is RES0.

`0b1` AMCR.HDBG is read/write.

Bits [23:14]

Reserved, RAZ.

SIZE, bits [13:8]

Defines the size of activity monitor event counters.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The size of the activity monitor event counters implemented by the Activity Monitors Extension is defined as [AMCFGR.SIZE + 1].

From Armv8, the counters are 64-bit, and so this field is `0b111111`.

Note

Software also uses this field to determine the spacing of counters in the memory-map. From Armv8, the counters are at doubleword-aligned addresses.

N, bits [7:0]

Defines the number of activity monitor event counters.

The total number of counters implemented in all groups by the Activity Monitors Extension is defined as [AMCFGR.N + 1].

Accessing the AMCFGR:

AMCFGR can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xE00`	AMCFGR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.2 AMCGCR, Activity Monitors Counter Group Configuration Register

The AMCGCR characteristics are:

Purpose

Provides information on the number of activity monitor event counters implemented within each counter group.

Configurations

External register AMCGCR[31:0] is architecturally mapped to AArch64 System register AMCGCR_EL0[31:0].

External register AMCGCR[31:0] is architecturally mapped to AArch32 System register AMCGCR[31:0].

The power domain of AMCGCR is IMPLEMENTATION DEFINED.

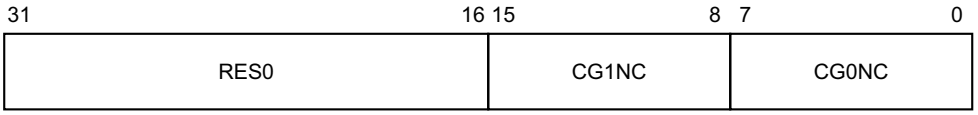
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCGCR are RES0.

Attributes

AMCGCR is a 32-bit register.

Field descriptions

The AMCGCR bit assignments are:



Bits [31:16]

Reserved, RES0.

CG1NC, bits [15:8]

Counter Group 1 Number of Counters. The number of counters in the auxiliary counter group.

In AMUv1, the permitted range of values is 0 to 16.

CG0NC, bits [7:0]

Counter Group 0 Number of Counters. The number of counters in the architected counter group.

In AMUv1, the value of this field is 4.

Accessing the AMCGCR:

AMCGCR can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0xCE0	AMCGCR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.3 AMCIDR0, Activity Monitors Component Identification Register 0

The AMCIDR0 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Component Identification scheme* on page K2-7663 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMCIDR0 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

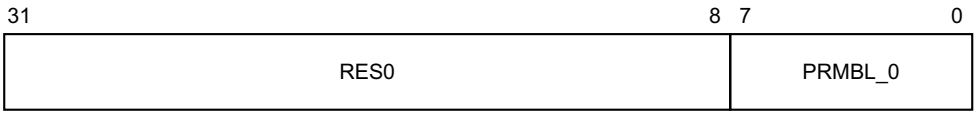
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR0 are RES0.

Attributes

AMCIDR0 is a 32-bit register.

Field descriptions

The AMCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the AMCIDR0:

AMCIDR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFF0`	AMCIDR0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.4 AMCIDR1, Activity Monitors Component Identification Register 1

The AMCIDR1 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Component Identification scheme* on page K2-7663 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMCIDR1 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

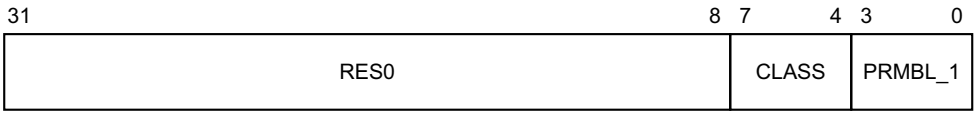
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR1 are RES0.

Attributes

AMCIDR1 is a 32-bit register.

Field descriptions

The AMCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, CoreSight component.

PRMBL_1, bits [3:0]

Preamble. Reads as `0x0`.

Accessing the AMCIDR1:

AMCIDR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFF4`	AMCIDR1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.5 AMCIDR2, Activity Monitors Component Identification Register 2

The AMCIDR2 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Component Identification scheme* on page K2-7663 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMCIDR2 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

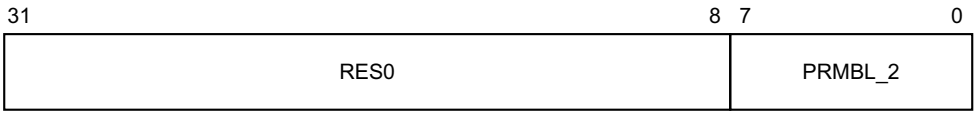
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR2 are RES0.

Attributes

AMCIDR2 is a 32-bit register.

Field descriptions

The AMCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Reads as `0x05`.

Accessing the AMCIDR2:

AMCIDR2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFF8`	AMCIDR2

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.6 AMCIDR3, Activity Monitors Component Identification Register 3

The AMCIDR3 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Component Identification scheme* on page K2-7663 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMCIDR3 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

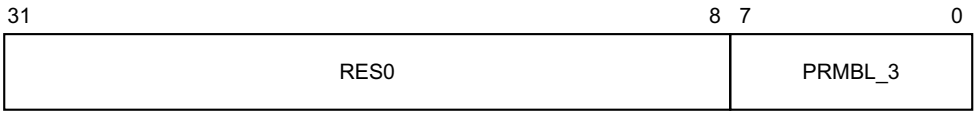
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCIDR3 are RES0.

Attributes

AMCIDR3 is a 32-bit register.

Field descriptions

The AMCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Reads as `0xB1`.

Accessing the AMCIDR3:

AMCIDR3 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFFC`	AMCIDR3

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.7 AMCNTENCLR0, Activity Monitors Count Enable Clear Register 0

The AMCNTENCLR0 characteristics are:

Purpose

Disable control bits for the architected s event counters, AMEVCNTR0<n>.

Configurations

External register AMCNTENCLR0[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR0_EL0[31:0].

External register AMCNTENCLR0[31:0] is architecturally mapped to AArch32 System register AMCNTENCLR0[31:0].

The power domain of AMCNTENCLR0 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

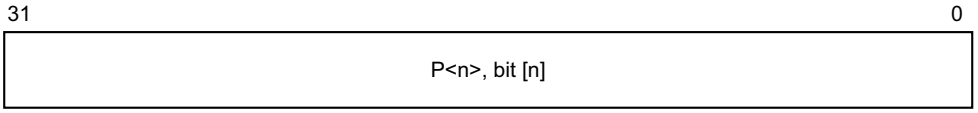
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR0 are RES0.

Attributes

AMCNTENCLR0 is a 32-bit register.

Field descriptions

The AMCNTENCLR0 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Activity monitor event counter disable bit for AMEVCNTR0<n>.

Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG0NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR0<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR0<n> is enabled. When written, disables AMEVCNTR0<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENCLR0:

AMCNTENCLR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xC20`	AMCNTENSET0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.8 AMCNTENCLR1, Activity Monitors Count Enable Clear Register 1

The AMCNTENCLR1 characteristics are:

Purpose

Disable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

Configurations

External register AMCNTENCLR1[31:0] is architecturally mapped to AArch64 System register AMCNTENCLR1_EL0[31:0].

External register AMCNTENCLR1[31:0] is architecturally mapped to AArch32 System register AMCNTENCLR1[31:0].

The power domain of AMCNTENCLR1 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

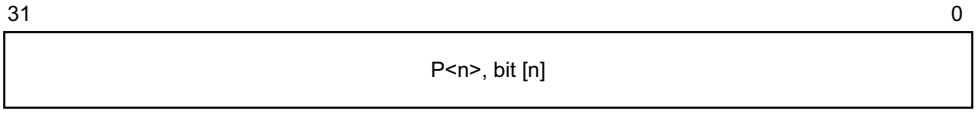
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENCLR1 are RES0.

Attributes

AMCNTENCLR1 is a 32-bit register.

Field descriptions

The AMCNTENCLR1 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Activity monitor event counter disable bit for AMEVCNTR1<n>.

Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG1NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR1<n> is enabled. When written, disables AMEVCNTR1<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENCLR1:

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENCLR1 are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

Note

The number of auxiliary activity monitor event counters implemented is zero exactly when AMCFGR.NCG == `0b0000`.

AMCNTENCLR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xC24`	AMCNTENCLR1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.9 AMCNTENSET0, Activity Monitors Count Enable Set Register 0

The AMCNTENSET0 characteristics are:

Purpose

Enable control bits for the architected activity monitors event counters, AMEVCNTR0<n>.

Configurations

External register AMCNTENSET0[31:0] is architecturally mapped to AArch64 System register AMCNTENSET0_EL0[31:0].

External register AMCNTENSET0[31:0] is architecturally mapped to AArch32 System register AMCNTENSET0[31:0].

The power domain of AMCNTENSET0 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

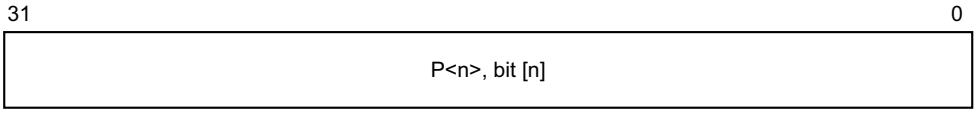
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET0 are RES0.

Attributes

AMCNTENSET0 is a 32-bit register.

Field descriptions

The AMCNTENSET0 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Activity monitor event counter enable bit for AMEVCNTR0<n>.

Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG0NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR0<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR0<n> is enabled. When written, enables AMEVCNTR0<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENSET0:

AMCNTENSET0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xC00`	AMCNTENSET0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.10 AMCNTENSET1, Activity Monitors Count Enable Set Register 1

The AMCNTENSET1 characteristics are:

Purpose

Enable control bits for the auxiliary activity monitors event counters, AMEVCNTR1<n>.

Configurations

External register AMCNTENSET1[31:0] is architecturally mapped to AArch64 System register AMCNTENSET1_EL0[31:0].

External register AMCNTENSET1[31:0] is architecturally mapped to AArch32 System register AMCNTENSET1[31:0].

The power domain of AMCNTENSET1 is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

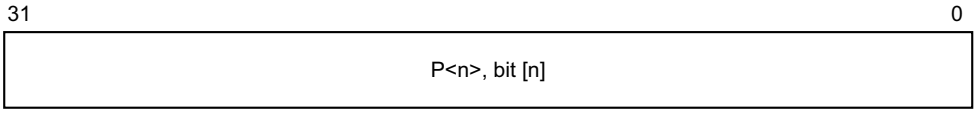
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCNTENSET1 are RES0.

Attributes

AMCNTENSET1 is a 32-bit register.

Field descriptions

The AMCNTENSET1 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Activity monitor event counter enable bit for AMEVCNTR1<n>.

Bits [31:N] are RAZ/WI. N is the value in AMCGCR.CG1NC.

Possible values of each bit are:

`0b0` When read, means that AMEVCNTR1<n> is disabled. When written, has no effect.

`0b1` When read, means that AMEVCNTR1<n> is enabled. When written, enables AMEVCNTR1<n>.

On a Cold reset, this field resets to `0`.

Accessing the AMCNTENSET1:

If the number of auxiliary activity monitor event counters implemented is zero, reads and writes of AMCNTENSET1 are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

Note

The number of auxiliary activity monitor counters implemented is zero exactly when AMCFGR.NCG == `0b0000`.

AMCNTENSET1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xC04`	AMCNTENSET1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.11 AMCR, Activity Monitors Control Register

The AMCR characteristics are:

Purpose

Global control register for the activity monitors implementation. AMCR is applicable to both the architected and the auxiliary counter groups.

Configurations

External register AMCR[31:0] is architecturally mapped to AArch64 System register AMCR_EL0[31:0].

External register AMCR[31:0] is architecturally mapped to AArch32 System register AMCR[31:0].

The power domain of AMCR is IMPLEMENTATION DEFINED.

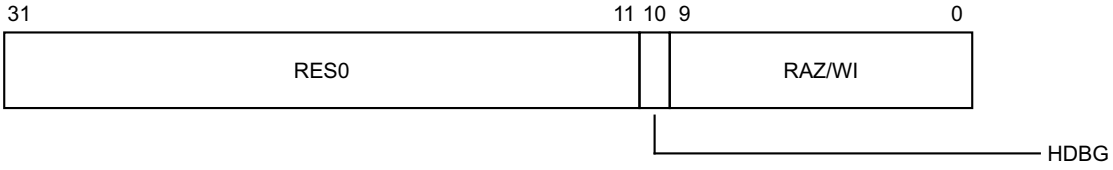
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMCR are RES0.

Attributes

AMCR is a 32-bit register.

Field descriptions

The AMCR bit assignments are:



Bits [31:11]

Reserved, RES0.

HDBG, bit [10]

This bit controls whether activity monitor counting is halted when the PE is halted in Debug state.

`0b0` Activity monitors do not halt counting when the PE is halted in Debug state.

`0b1` Activity monitors halt counting when the PE is halted in Debug state.

Bits [9:0]

Reserved, RAZ/WI.

Accessing the AMCR:

AMCR can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xE04`	AMCR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.12 AMDEVAFF0, Activity Monitors Device Affinity Register 0

The AMDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the AMU component relates to.

Configurations

The power domain of AMDEVAFF0 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

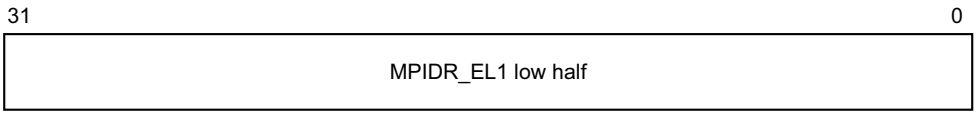
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVAFF0 are RES0.

Attributes

AMDEVAFF0 is a 32-bit register.

Field descriptions

The AMDEVAFF0 bit assignments are:



MPIDR_EL1 low half, bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the AMDEVAFF0:

AMDEVAFF0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0xFA8	AMDEVAFF0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.13 AMDEVAFF1, Activity Monitors Device Affinity Register 1

The AMDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the AMU component relates to.

Configurations

The power domain of AMDEVAFF1 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

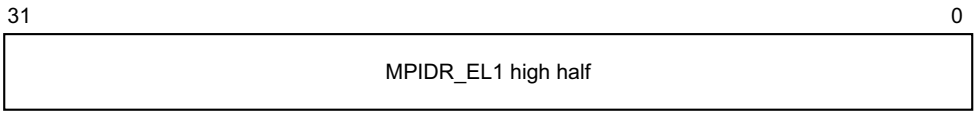
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVAFF1 are RES0.

Attributes

AMDEVAFF1 is a 32-bit register.

Field descriptions

The AMDEVAFF1 bit assignments are:



MPIDR_EL1 high half, bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented Exception level.

Accessing the AMDEVAFF1:

AMDEVAFF1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0xFAC	AMDEVAFF1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.14 AMDEVARCH, Activity Monitors Device Architecture Register

The AMDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the AMU component.

Configurations

The power domain of AMDEVARCH is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

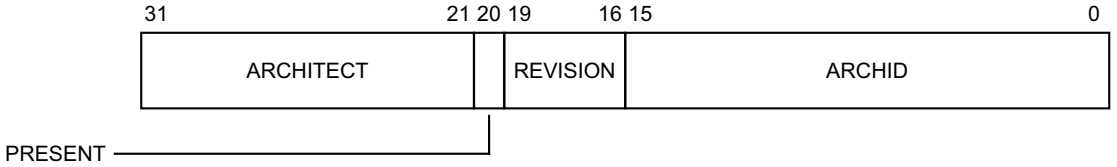
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVARCH are RES0.

Attributes

AMDEVARCH is a 32-bit register.

Field descriptions

The AMDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For AMU, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, `0x4`.

Bits [27:21] are the JEP106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in Armv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

`0b0000` Architecture revision is AMUv1.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an AMU component. For architectures defined by Arm this is further subdivided.

For AMU:

- Bits [15:12] are the architecture version, `0x0`.
- Bits [11:0] are the architecture part number, `0xA66`.

This corresponds to AMU architecture version AMUv1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the AMDEVARCH:

AMDEVARCH can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0xFBC	AMDEVARCH

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.15 AMDEVTYPE, Activity Monitors Device Type Register

The AMDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE's performance monitor interface.

Configurations

The power domain of AMDEVTYPE is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

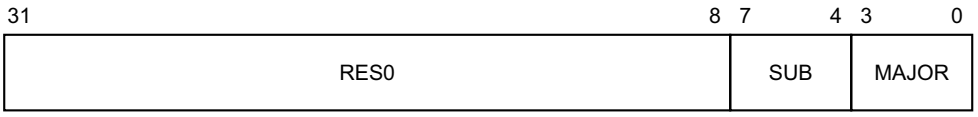
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMDEVTYPE are RES0.

Attributes

AMDEVTYPE is a 32-bit register.

Field descriptions

The AMDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Reads as `0x1`, to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Reads as `0x6`, to indicate this is a performance monitor component.

Accessing the AMDEVTYPE:

AMDEVTYPE can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFCC`	AMDEVTYPE

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.16 AMEVCNTR0<n>, Activity Monitors Event Counter Registers 0, n = 0 - 15

The AMEVCNTR0<n> characteristics are:

Purpose

Provides access to the architected activity monitor event counters.

Configurations

External register AMEVCNTR0<n>[63:0] is architecturally mapped to AArch64 System register AMEVCNTR0<n>_EL0[63:0].

External register AMEVCNTR0<n>[63:0] is architecturally mapped to AArch32 System register AMEVCNTR0<n>[63:0].

The power domain of AMEVCNTR0<n> is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

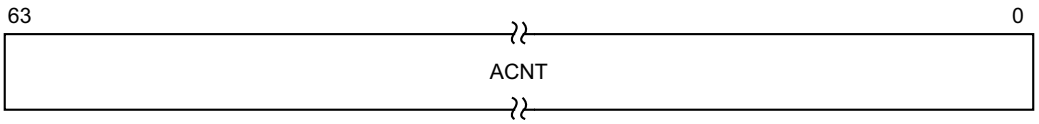
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR0<n> are RES0.

Attributes

AMEVCNTR0<n> is a 64-bit register.

Field descriptions

The AMEVCNTR0<n> bit assignments are:



ACNT, bits [63:0]

Architected activity monitor event counter n.

Value of architected activity monitor event counter n, where n is the number of this register and is a number from 0 to 15.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to `0`.

Accessing the AMEVCNTR0<n>:

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n> are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

Note

AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

AMEVCNTR0<n>[31:0] can be accessed through its memory-mapped interface:

Component	Offset	Instance	Range
AMU	`0x000` + 8n	AMEVCNTR0<n>	31:0

This interface is accessible as follows:

- Accesses to AMEVCNTR0<n>[31:0] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMEVCNTR0<n>[63:32] can be accessed through its memory-mapped interface:

Component	Offset	Instance	Range
AMU	0x004 + 8n	AMEVCNTR0<n>	63:32

This interface is accessible as follows:

- Accesses to AMEVCNTR0<n>[63:32] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.17 AMEVCNTR1<n>, Activity Monitors Event Counter Registers 1, n = 0 - 15

The AMEVCNTR1<n> characteristics are:

Purpose

Provides access to the auxiliary activity monitor event counters.

Configurations

External register AMEVCNTR1<n>[63:0] is architecturally mapped to AArch64 System register AMEVCNTR1<n>_EL0[63:0].

External register AMEVCNTR1<n>[63:0] is architecturally mapped to AArch32 System register AMEVCNTR1<n>[63:0].

The power domain of AMEVCNTR1<n> is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

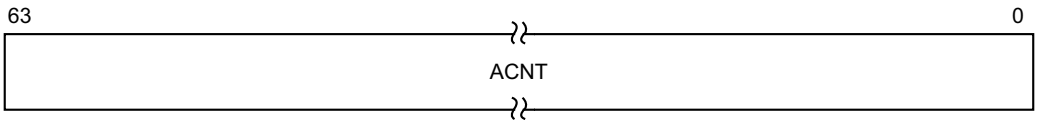
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVCNTR1<n> are RES0.

Attributes

AMEVCNTR1<n> is a 64-bit register.

Field descriptions

The AMEVCNTR1<n> bit assignments are:



ACNT, bits [63:0]

Auxiliary activity monitor event counter n.

Value of auxiliary activity monitor event counter n, where n is the number of this register and is a number from 0 to 15.

If the counter is enabled, writes to this register have UNPREDICTABLE results.

On a Cold reset, this field resets to `0`.

Accessing the AMEVCNTR1<n>:

If <n> is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1<n> are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

Note

AMCGCR.CG1NC identifies the number of auxiliary activity monitor event counters.

AMEVCNTR1<n>[31:0] can be accessed through its memory-mapped interface:

Component	Offset	Instance	Range
AMU	`0x100` + 8n	AMEVCNTR1<n>	31:0

This interface is accessible as follows:

- Accesses to AMEVCNTR1<n>[31:0] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMEVCNTR1<n>[63:32] can be accessed through its memory-mapped interface:

Component	Offset	Instance	Range
AMU	0x104 + 8n	AMEVCNTR1<n>	63:32

This interface is accessible as follows:

- Accesses to AMEVCNTR1<n>[63:32] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.18 AMEVTYPER0<n>, Activity Monitors Event Type Registers 0, n = 0 - 15

The AMEVTYPER0<n> characteristics are:

Purpose

Provides information on the events that an architected activity monitor event counter AMEVCNTR0<n> counts.

Configurations

External register AMEVTYPER0<n>[31:0] is architecturally mapped to AArch64 System register AMEVTYPER0<n>_EL0[31:0].

External register AMEVTYPER0<n>[31:0] is architecturally mapped to AArch32 System register AMEVTYPER0<n>[31:0].

The power domain of AMEVTYPER0<n> is IMPLEMENTATION DEFINED.

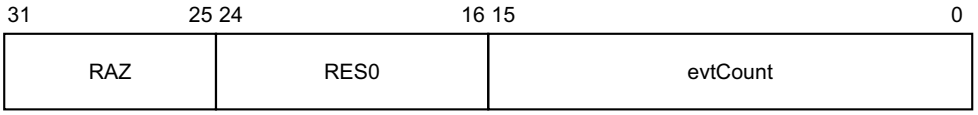
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPER0<n> are RES0.

Attributes

AMEVTYPER0<n> is a 32-bit register.

Field descriptions

The AMEVTYPER0<n> bit assignments are:



Bits [31:25]

Reserved, RAZ.

Bits [24:16]

Reserved, RES0.

evtCount, bits [15:0]

Event to count. The event number of the event that is counted by the architected activity monitor event counter AMEVCNTR0<n>. The value of this field is architecturally mandated for each architected counter.

The following table shows the mapping between required event numbers and the corresponding counters:

`0x0011` **When n == 0** Processor frequency cycles

`0x4004` **When n == 1** Constant frequency cycles

`0x0008` **When n == 2** Instructions retired

`0x4005` **When n == 3** Memory stall cycles

Accessing the AMEVTYPER0<n>:

If <n> is greater than or equal to the number of architected activity monitor event counters, reads and writes of AMEVTYPER0<n> are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

Note

AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMEVTYPER0<n> can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0x400` + 4n	AMEVTYPER0<n>

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.19 AMEVTYPER1<n>, Activity Monitors Event Type Registers 1, n = 0 - 15

The AMEVTYPER1<n> characteristics are:

Purpose

Provides information on the events that an auxiliary activity monitor event counter AMEVCNTR1<n> counts.

Configurations

External register AMEVTYPER1<n>[31:0] is architecturally mapped to AArch64 System register AMEVTYPER1<n>_EL0[31:0].

External register AMEVTYPER1<n>[31:0] is architecturally mapped to AArch32 System register AMEVTYPER1<n>[31:0].

The power domain of AMEVTYPER1<n> is IMPLEMENTATION DEFINED.

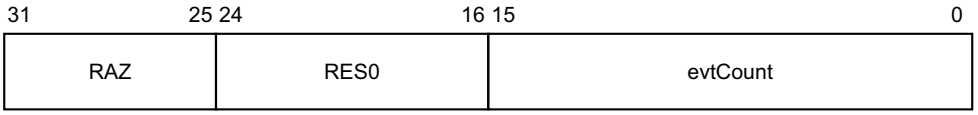
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMEVTYPER1<n> are RES0.

Attributes

AMEVTYPER1<n> is a 32-bit register.

Field descriptions

The AMEVTYPER1<n> bit assignments are:



Bits [31:25]

Reserved, RAZ.

Bits [24:16]

Reserved, RES0.

evtCount, bits [15:0]

Event to count. The event number of the event that is counted by the auxiliary activity monitor event counter AMEVCNTR1<n>.

It is IMPLEMENTATION DEFINED what values are supported by each counter.

If software writes a value to this field which is not supported by the corresponding counter AMEVCNTR1<n>, then:

- It is UNPREDICTABLE which event will be counted.
- The value read back is UNKNOWN.

Note

The event counted by AMEVCNTR1<n> might be fixed at implementation. In this case, the field is read-only and writes are UNDEFINED.

If the corresponding counter AMEVCNTR1<n> is enabled, writes to this register have UNPREDICTABLE results.

Accessing the AMEVTYPER1<n>:

If <n> is greater than or equal to the number of auxiliary activity monitor event counters, reads and writes of AMEVTYPER1<n> are CONSTRAINED UNPREDICTABLE, and accesses to the register behave as RAZ/WI.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

AMCGCR.CG1NC identifies the number of auxiliary activity monitor event counters.

AMEVTYPER1<n> can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0x480 + 4n	AMEVTYPER1<n>

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.20 AMIIDR, Activity Monitors Implementation Identification Register

The AMIIDR characteristics are:

Purpose

Defines the implementer and revisions of the AMU.

Configurations

The power domain of AMIIDR is IMPLEMENTATION DEFINED.

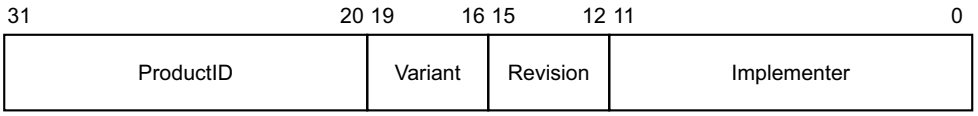
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMIIDR are RES0.

Attributes

AMIIDR is a 32-bit register.

Field descriptions

The AMIIDR bit assignments are:



ProductID, bits [31:20]

This field is an AMU part identifier.

The value of this field is IMPLEMENTATION DEFINED.

If AMPIDR0 is implemented, AMPIDR0.PART_0 matches bits [27:20] of this field.

If AMPIDR1 is implemented, AMPIDR1.PART_1 matches bits [31:28] of this field.

Variant, bits [19:16]

This field distinguishes product variants or major revisions of the product.

The value of this field is IMPLEMENTATION DEFINED.

If AMPIDR2 is implemented, AMPIDR2.REVISION matches AMIIDR.Variant.

Revision, bits [15:12]

This field distinguishes minor revisions of the product.

The value of this field is IMPLEMENTATION DEFINED.

If AMPIDR3 is implemented, AMPIDR3.REVAND matches AMIIDR.Revision.

Implementer, bits [11:0]

Contains the JEP106 code of the company that implemented the AMU.

For an Arm implementation, this field reads as `0x43B`.

Bits [11:8] contain the JEP106 continuation code of the implementer.

Bit 7 is RES0

Bits [6:0] contain the JEP106 identity code of the implementer.

If AMPIDR4 is implemented, AMPIDR4.DES_2 matches bits [11:8] of this field.

If AMPIDR2 is implemented, AMPIDR2.DES_1 matches bits [6:4] of this field.

If AMPIDR1 is implemented, AMPIDR1.DES_0 matches bits [3:0] of this field.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the AMIIDR:

AMIIDR can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0xE08	AMIIDR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.21 AMPIDR0, Activity Monitors Peripheral Identification Register 0

The AMPIDR0 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMPIDR0 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

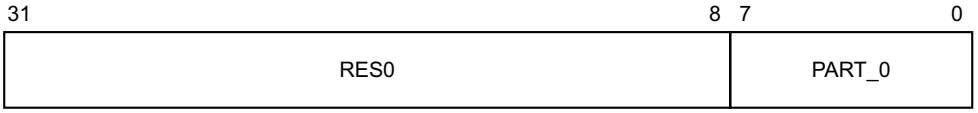
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR0 are RES0.

Attributes

AMPIDR0 is a 32-bit register.

Field descriptions

The AMPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

The value of this field is IMPLEMENTATION DEFINED.

Accessing the AMPIDR0:

AMPIDR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0xFE0	AMPIDR0

This interface is accessible as follows:

- Accesses to this register are RO.

I5.5.22 AMPIDR1, Activity Monitors Peripheral Identification Register 1

The AMPIDR1 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMPIDR1 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

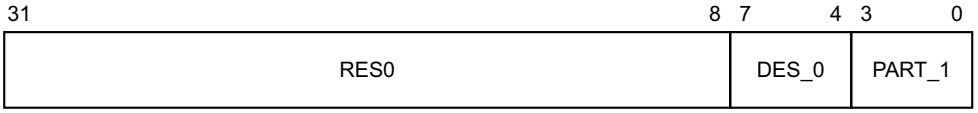
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR1 are RES0.

Attributes

AMPIDR1 is a 32-bit register.

Field descriptions

The AMPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code.

The value of this field is IMPLEMENTATION DEFINED. For Arm Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

The value of this field is IMPLEMENTATION DEFINED.

Accessing the AMPIDR1:

AMPIDR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFE4`	AMPIDR1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.23 AMPIDR2, Activity Monitors Peripheral Identification Register 2

The AMPIDR2 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMPIDR2 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

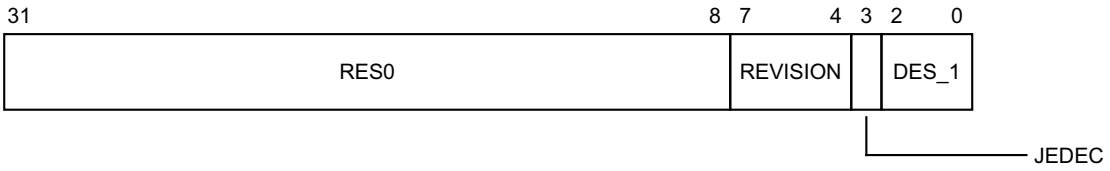
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR2 are RES0.

Attributes

AMPIDR2 is a 32-bit register.

Field descriptions

The AMPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

The value of this field is IMPLEMENTATION DEFINED.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code.

The value of this field is IMPLEMENTATION DEFINED. For Arm Limited, this field is `0b011`.

Accessing the AMPIDR2:

AMPIDR2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFE8`	AMPIDR2

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.24 AMPIDR3, Activity Monitors Peripheral Identification Register 3

The AMPIDR3 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMPIDR3 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

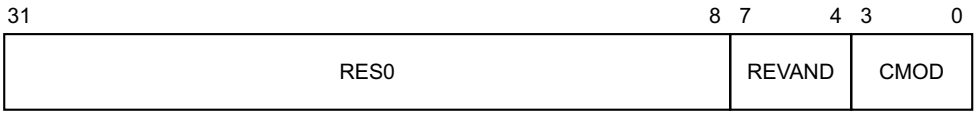
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR3 are RES0.

Attributes

AMPIDR3 is a 32-bit register.

Field descriptions

The AMPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using AMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

The value of this field is IMPLEMENTATION DEFINED.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

The value of this field is IMPLEMENTATION DEFINED.

Accessing the AMPIDR3:

AMPIDR3 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	0xFEC	AMPIDR3

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.5.25 AMPIDR4, Activity Monitors Peripheral Identification Register 4

The AMPIDR4 characteristics are:

Purpose

Provides information to identify an activity monitors component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

The power domain of AMPIDR4 is IMPLEMENTATION DEFINED.

Implementation of this register is OPTIONAL.

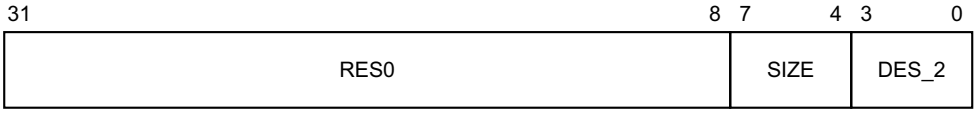
This register is present only when AMUv1 is implemented. Otherwise, direct accesses to AMPIDR4 are RES0.

Attributes

AMPIDR4 is a 32-bit register.

Field descriptions

The AMPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

This field reads as `0b0000`.

DES_2, bits [3:0]

Designer. JEP106 continuation code, least significant nibble.

The value of this field is IMPLEMENTATION DEFINED. For Arm Limited, this field is `0b0100`.

Accessing the AMPIDR4:

AMPIDR4 can be accessed through its memory-mapped interface:

Component	Offset	Instance
AMU	`0xFD0`	AMPIDR4

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.6 Generic Timer memory-mapped registers overview

The Generic Timer memory-mapped registers are implemented as multiple register frames, with each register frame having its own base address, as follows:

- A single CNTCTLBase register frame, at base address CNTCTLBase.
- Between one and seven CNTBase*N* register frames, each with its own base address CNTBase*N*.
- For each CNTBase*N* register frame, if required, a CNTEL0Base*N* register frame, at base address CNTEL0Base*N*, that provides an EL0 view of the CNTBase*N* register frame.

For more information, see:

- *Memory-mapped timer components* on page I2-7020.
- *The CNTBaseN and CNTEL0BaseN frames* on page I2-7022. This section includes the memory map of the CNTBase*N* and CNTBase*N* register frames.
- *The CNTCTLBase frame* on page I2-7021. This section includes the memory map of the CNTCTLBase register frame.

Note

Providing a complete set of features in a system level implementation on page K5-7686 gives an implementation example for a system level implementation of the Generic Timer.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7 Generic Timer memory-mapped register descriptions

This section describes the Generic Timer registers. *Generic Timer memory-mapped registers overview* on page I5-7150 gives an overview of these registers, and includes links to their memory maps.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:

- CNTNSAR controls whether CNTACR<n> is accessible by Non-secure accesses.
- If frame CNTEL0BaseN is implemented, the CNTEL0ACR in frame CNTBaseN provides additional control of accesses to frame CNTEL0BaseN.

Configurations

The power domain of CNTACR<n> is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I2-7015*.

Implemented only if the value of CNTTIDR.Frame<n> is 1.

An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:

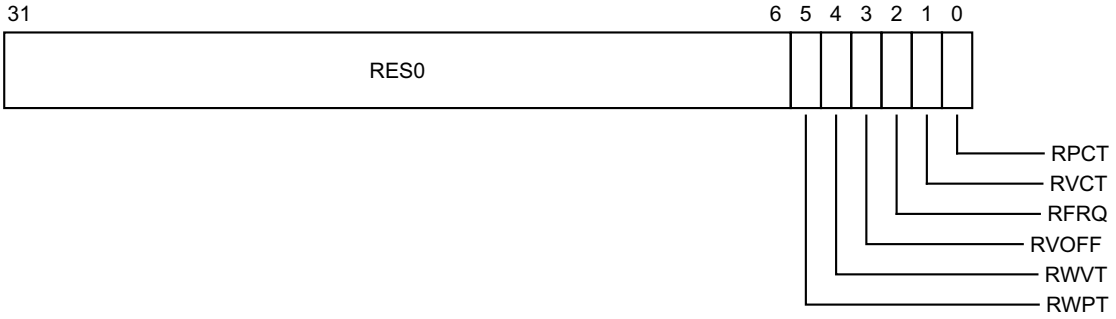
- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

Attributes

CNTACR<n> is a 32-bit register.

Field descriptions

The CNTACR<n> bit assignments are:



Bits [31:6]

Reserved, RES0.

RWPT, bit [5]

Read/write access to the EL1 Physical Timer registers CNTP_CVAL, CNTP_TVAL, and CNTP_CTL, in frame <n>. The possible values of this bit are:

`0b0` No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.

`0b1` Read/write access to the EL1 Physical Timer registers in frame <n>.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RWVT, bit [4]

Read/write access to the Virtual Timer register CNTV_CVAL, CNTV_TVAL, and CNTV_CTL, in frame <n>. The possible values of this bit are:

`0b0` No access to the Virtual Timer registers in frame <n>. The registers are RES0.

`0b1` Read/write access to the Virtual Timer registers in frame <n>.

This field resets to an architecturally UNKNOWN value.

RVOFF, bit [3]

Read-only access to CNTVOFF, in frame <n>. The possible values of this bit are:

`0b0` No access to CNTVOFF in frame <n>. The register is RES0.

`0b1` Read-only access to CNTVOFF in frame <n>.

This field resets to an architecturally UNKNOWN value.

RFRQ, bit [2]

Read-only access to CNTFRQ, in frame <n>. The possible values of this bit are:

`0b0` No access to CNTFRQ in frame <n>. The register is RES0.

`0b1` Read-only access to CNTFRQ in frame <n>.

This field resets to an architecturally UNKNOWN value.

RVCT, bit [1]

Read-only access to CNTVCT, in frame <n>. The possible values of this bit are:

`0b0` No access to CNTVCT in frame <n>. The register is RES0.

`0b1` Read-only access to CNTVCT in frame <n>.

This field resets to an architecturally UNKNOWN value.

RPCT, bit [0]

Read-only access to CNTPCT, in frame <n>. The possible values of this bit are:

`0b0` No access to CNTPCT in frame <n>. The register is RES0.

`0b1` Read-only access to CNTPCT in frame <n>.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTACR<n>:

In a system that recognizes two Security states:

- CNTACR<n> is always accessible by Secure accesses.
- CNTNSAR.NS<n> determines whether CNTACR<n> is accessible by Non-secure accesses.

CNTACR<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	`0x040` + 4n	CNTACR<n>

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

Configurations

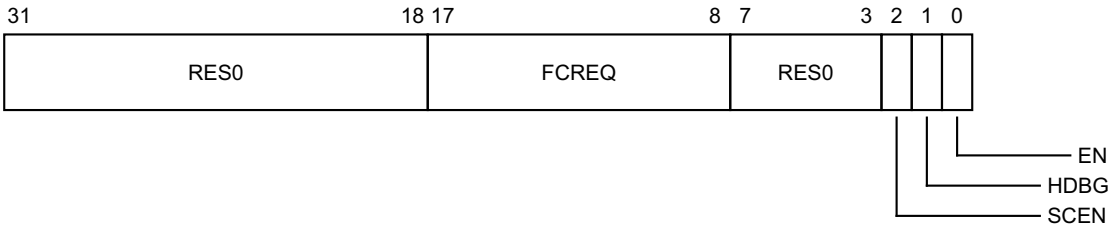
The power domain of CNTCR is IMPLEMENTATION DEFINED. Some or all RW fields of this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain.

Attributes

CNTCR is a 32-bit register.

Field descriptions

The CNTCR bit assignments are:



Bits [31:18]

Reserved, RES0.

FCREQ, bits [17:8]

Frequency change request. Indicates the number of the entry in the Frequency modes table to select.

Selecting an unimplemented entry, or an entry that contains 0, has no effect on the counter.

The maximum number of entries in the Frequency modes table is IMPLEMENTATION DEFINED up to a maximum of 1004 entries, see *The Frequency modes table* on page I2-7017. An implementation is only required to implement an FCREQ field that can hold values from 0 to the highest supported Frequency modes table entry. Any unrequired most-significant bits of FCREQ can be implemented as RES0.

This field resets to `0`.

Bits [7:3]

Reserved, RES0.

SCEN, bit [2]

When ARMv8.4-CNTSC is implemented:

Scale Enable.

`0b0` Scaling is not enabled. The counter value is incremented by `0x1.0000000` for each counter tick.

`0b1` Scaling is enabled. The counter is incremented by CNTSCR.ScaleVal for each counter tick.

The SCEN bit can only be changed when the counter is disabled, when CNTCR.EN == 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the value of CNTCR.SCEN changes when CNTCR.EN == 1 then:

- The counter value becomes UNKNOWN.
- The counter value remains UNKNOWN on future ticks of the clock.

When the CNTCV register in the CNTControlBase frame of the memory mapped counter module is written to, the accumulated fraction information is reset to zero.

This field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HDBG, bit [1]

Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:

`0b0` System counter ignores Halt-on-debug.

`0b1` Asserted Halt-on-debug signal halts system counter update.

This field resets to an architecturally UNKNOWN value.

EN, bit [0]

Enables the counter:

`0b0` System counter disabled.

`0b1` System counter enabled.

This field resets to `0`.

Accessing the CNTCR:

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

CNTCR can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	`0x000`	CNTCR

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

Purpose

Indicates the current count value.

Configurations

The power domain of CNTCV is IMPLEMENTATION DEFINED.

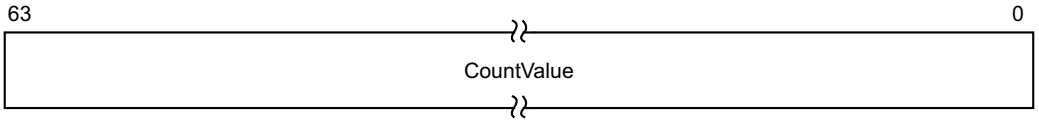
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTCV is a 64-bit register.

Field descriptions

The CNTCV bit assignments are:



CountValue, bits [63:0]

Indicates the counter value.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTCV:

Frame	Accessibility
CNTControlBase	RW
CNTReadBase	RO

A write to CNTCV must be visible in the CNTPCT register of each running processor in a finite time.

For the instance of the register in the CNTControlBase frame:

- In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, and therefore this register instance, is implemented only in the Secure memory map.
- If the counter is enabled, the effect of writing to the register is UNKNOWN.

In an implementation that supports 64-bit atomic memory accesses, this register must be accessible using a 64-bit atomic access.

CNTCV[63:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTControlBase	0x008	CNTCV	63:0

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to CNTCV[63:0] are RW.

CNTCV[63:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTReadBase	0x000	CNTCV	63:0

This interface is accessible as follows:

- Accesses to CNTCV[63:0] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.4 CNTEL0ACR, Counter-timer EL0 Access Control Register

The CNTEL0ACR characteristics are:

Purpose

An implementation of CNTEL0ACR in the frame at CNTBaseN controls whether the CNTPCT, CNTVCT, CNTFRQ, EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTEL0BaseN.

Configurations

The power domain of CNTEL0ACR is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I2-7015*.

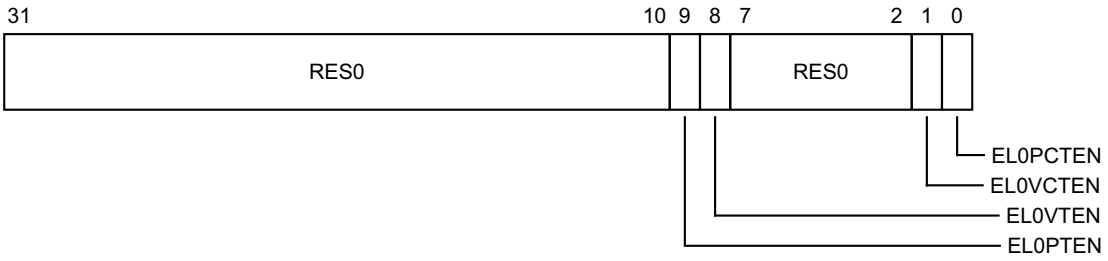
Implementation of this register is OPTIONAL.

Attributes

CNTEL0ACR is a 32-bit register.

Field descriptions

The CNTEL0ACR bit assignments are:



Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the CNTP_CVAL, CNTP_TVAL, and CNTP_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

`0b0` No access. Registers are RES0 in the second view.

`0b1` Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

This field resets to an architecturally UNKNOWN value.

EL0VTEN, bit [8]

Second view read/write access control for the Virtual Timer registers. This bit controls whether the CNTV_CVAL, CNTV_TVAL, and CNTV_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

`0b0` No access. Registers are RES0 in the second view.

`0b1` Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTEL0BaseN frame, regardless of the value of this bit.

This field resets to an architecturally UNKNOWN value.

Bits [7:2]

Reserved, RES0.

EL0VCTEN, bit [1]

Second view read access control for CNTVCT and CNTFRQ. The possible values of this bit are:

`0b0` CNTVCT is not visible in the second view.
If EL0PCTEN is set to 0, CNTFRQ is not visible in the second view.

`0b1` Access permitted. If CNTVCT and CNTFRQ are visible in the current frame then they are visible in the second view.

This field resets to an architecturally UNKNOWN value.

EL0PCTEN, bit [0]

Second view read access control for CNTPCT and CNTFRQ. The possible values of this bit are:

`0b0` CNTPCT is not visible in the second view.
If EL0VCTEN is set to 0, CNTFRQ is not visible in the second view.

`0b1` Access permitted. If CNTPCT and CNTFRQ are visible in the current frame then they are visible in the second view.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTEL0ACR:

CNTEL0ACR can be implemented in any implemented CNTBaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

If CNTEL0ACR is not implemented in an implemented CNTBaseN frame:

- The register location in that frame is RAZ/WI.
- If the corresponding CNTEL0BaseN frame is implemented, the registers CNTFRQ, CNTP_CTL, CNTP_CVAL, CNTP_TVAL, CNTPCT, CNTV_CTL, CNTV_CVAL, CNTV_TVAL, and CNTVCT are not visible in that frame.

CNTEL0ACR can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	`0x014`	CNTEL0ACR

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

Purpose

Indicates the base frequency of the system counter.

Configurations

The power domain of CNTFID0 is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0. For more information see *The Frequency modes table* on page I2-7017.

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

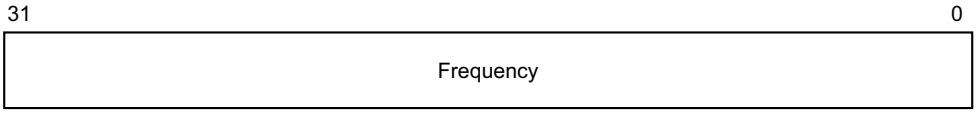
If the Frequency modes table is in read/write memory, Arm strongly recommends that the table is not updated once the system is running.

Attributes

CNTFID0 is a 32-bit register.

Field descriptions

The CNTFID0 bit assignments are:



Frequency, bits [31:0]

The base frequency of the system counter, in Hz.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTFID0:

It is IMPLEMENTATION DEFINED whether this register is RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

CNTFID0 can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x020	CNTFID0

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RO or RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.6 CNTFID<n>, Counter Frequency IDs, n > 0

The CNTFID<n> characteristics are:

Purpose

Indicates alternative system counter update frequencies.

Configurations

The power domain of CNTFID<n> is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0, see *The Frequency modes table* on page I2-7017.

The number of CNTFID<n> registers is IMPLEMENTATION DEFINED, and the only required CNTFID<n> register is CNTFID0.

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

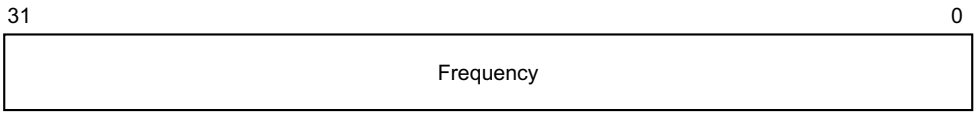
If the Frequency modes table is in read/write memory, Arm strongly recommends that the table is not updated once the system is running.

Attributes

CNTFID<n> is a 32-bit register.

Field descriptions

The CNTFID<n> bit assignments are:



Frequency, bits [31:0]

A system counter update frequency, in Hz. Must be an exact divisor of the base frequency. Arm strongly recommends that all frequency values in the Frequency modes table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

increment = (base frequency) / (selected frequency)

This field resets to an architecturally UNKNOWN value.

Accessing the CNTFID<n>:

It is IMPLEMENTATION DEFINED whether this register is RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes these registers, is implemented only in the Secure memory map.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CNTFID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x020 + 4n	CNTFID<n>

This interface is accessible as follows:

- Accesses to this register are RO or RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. The instance of the register in the CNTCTLBase frame must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Configurations

The power domain of CNTFRQ is IMPLEMENTATION DEFINED.

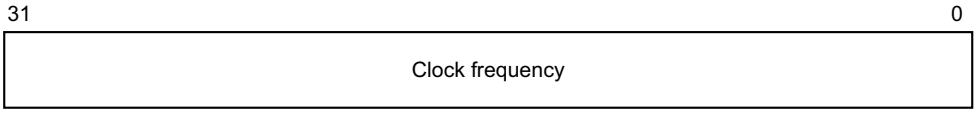
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:



Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTFRQ:

CNTFRQ must be implemented as an RW register in the CNTCTLBase frame.

In a system that recognizes two Security states, the instance of the register in the CNTCTLBase frame is only accessible by Secure accesses.

CNTFRQ can be implemented as a RO register in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTFRQ is accessible in that frame, as a RO register, if the value of CNTACR<n>.RFRQ is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For an implemented CNTEL0BaseN frame:

- CNTFRQ is accessible as a RO register in that frame if both:
  - CNTFRQ is accessible in the corresponding CNTBaseN frame.
  - Either the value of CNTEL0ACR.EL0VCTEN is 1 or the value of CNTEL0ACR.EL0PCTEN is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

CNTFRQ can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x010	CNTFRQ

This interface is accessible as follows:

- Accesses to this register are RO.

CNTFRQ can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0x010	CNTFRQ

This interface is accessible as follows:

- Accesses to this register are RO.

CNTFRQ can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	0x000	CNTFRQ

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.8 CNTID, Counter Identification Register

The CNTID characteristics are:

Purpose

Indicates whether counter scaling is implemented.

Configurations

The power domain of CNTID is IMPLEMENTATION DEFINED.

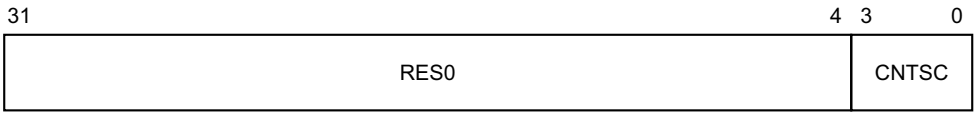
This register is present only when ARMv8.4-CNTSC is implemented. Otherwise, direct accesses to CNTID are RES0.

Attributes

CNTID is a 32-bit register.

Field descriptions

The CNTID bit assignments are:



Bits [31:4]

Reserved, RES0.

CNTSC, bits [3:0]

Indicates whether Counter Scaling is implemented

`0b0000` Counter scaling is not implemented.

`0b0001` Counter scaling is implemented.

All other values are reserved.

Accessing the CNTID:

In a system that supports Secure and Non-secure memory maps, the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

CNTID can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	`0x1C`	CNTID

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.9 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

Purpose

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

Configurations

The power domain of CNTNSAR is IMPLEMENTATION DEFINED.

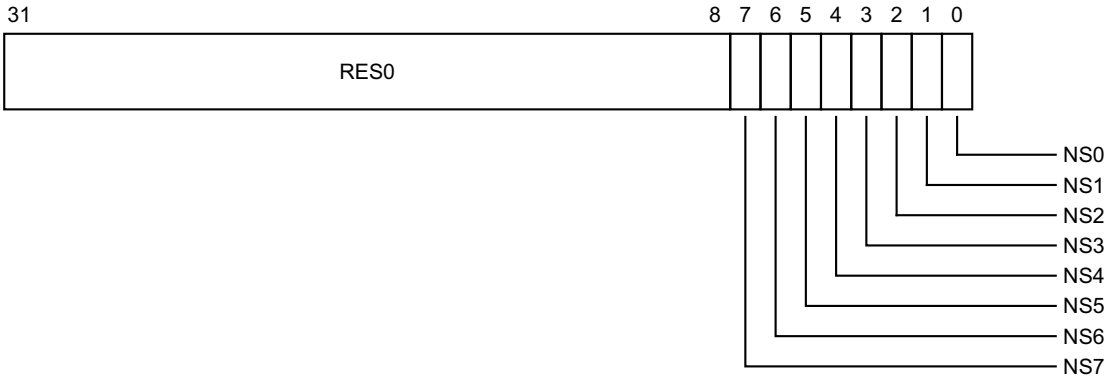
On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I2-7015*.

Attributes

CNTNSAR is a 32-bit register.

Field descriptions

The CNTNSAR bit assignments are:



Bits [31:8]

Reserved, RES0.

NS<n>, bit [n], for n = 0 to 7

Non-secure access to frame n. The possible values of this bit are:

`0b0` Secure access only. Behaves as RES0 to Non-secure accesses.

`0b1` Secure and Non-secure accesses permitted.

This bit also determines whether, in the CNTCTLBase frame, CNTACR<n> and CNTVOFF<n> are accessible to Non-secure accesses.

If frame CNTBase<n>:

- Is not implemented, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<n> is RES0.
- Is not Configurable access, and is accessible by both Secure and Non-secure accesses, then NS<n> is RES1.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the CNTNSAR:

In a system that recognizes two Security states, this register is only accessible by Secure accesses.

CNTNSAR can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	0x004	CNTNSAR

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.10 CNTP_CTL, Counter-timer Physical Timer Control

The CNTP_CTL characteristics are:

Purpose

Control register for the EL1 physical timer.

Configurations

The power domain of CNTP_CTL is IMPLEMENTATION DEFINED.

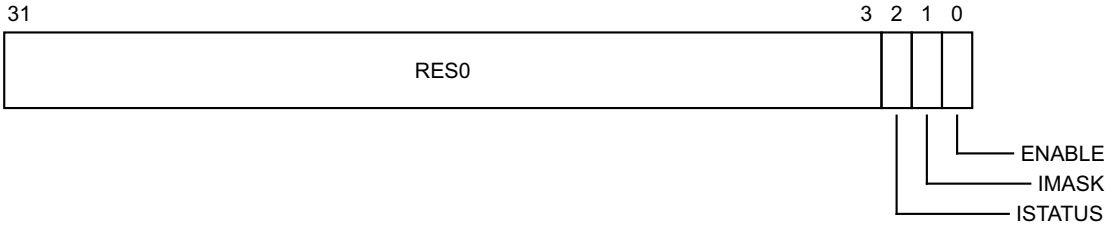
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_CTL:

CNTP_CTL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CTL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP_CTL is accessible in that frame if both:
  - CNTP_CTL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

CNTP_CTL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	`0x02C`	CNTP_CTL

This interface is accessible as follows:

- Accesses to this register are RW.

CNTP_CTL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	`0x02C`	CNTP_CTL

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

I5.7.11 CNTP_CVAL, Counter-timer Physical Timer CompareValue

The CNTP_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the EL1 physical timer.

Configurations

The power domain of CNTP_CVAL is IMPLEMENTATION DEFINED.

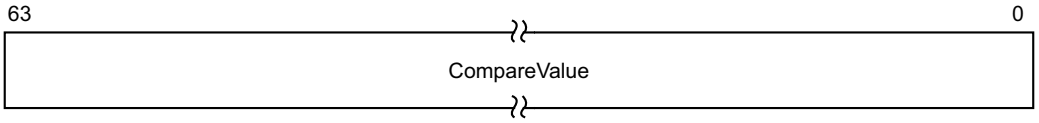
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

The CNTP_CVAL bit assignments are:



CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- An interrupt is generated if CNTP_CTL.IMASK is 0.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_CVAL:

CNTP_CVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_CVAL address in that frame is RAZ/WI.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For an implemented CNTEL0BaseN frame:

- CNTP_CVAL is accessible in that frame if both:
  - CNTP_CVAL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTP_CVAL register must be accessible as an atomic 64-bit value.

CNTP_CVAL[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x020	CNTP_CVAL	31:0

This interface is accessible as follows:

- Accesses to CNTP_CVAL[31:0] are RW.

CNTP_CVAL[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x020	CNTP_CVAL	31:0

This interface is accessible as follows:

- Accesses to CNTP_CVAL[31:0] are RW.

CNTP_CVAL[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x024	CNTP_CVAL	63:32

This interface is accessible as follows:

- Accesses to CNTP_CVAL[63:32] are RW.

CNTP_CVAL[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x024	CNTP_CVAL	63:32

This interface is accessible as follows:

- Accesses to CNTP_CVAL[63:32] are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.12 CNTP_TVAL, Counter-timer Physical Timer TimerValue

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Configurations

The power domain of CNTP_TVAL is IMPLEMENTATION DEFINED.

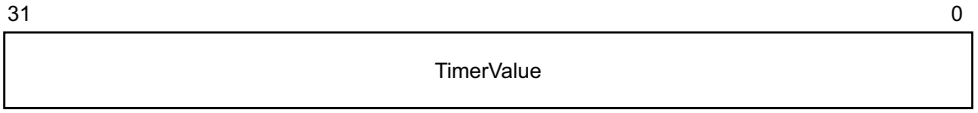
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL.ENABLE is 1, the value returned is (CompareValue - CNTPCT).

On a write of this register, CompareValue is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.
- If CNTP_CTL.IMASK is 0, an interrupt is generated.

When CNTP_CTL.ENABLE is 0, the timer condition is not met, but CNTPCT continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTP_TVAL:

CNTP_TVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_TVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_TVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP_TVAL is accessible in that frame if both:
  - CNTP_TVAL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP_TVAL address in that frame is RAZ/WI.

CNTP_TVAL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x028	CNTP_TVAL

This interface is accessible as follows:

- Accesses to this register are RW.

CNTP_TVAL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0x028	CNTP_TVAL

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.13 CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

Configurations

The power domain of CNTPCT is IMPLEMENTATION DEFINED.

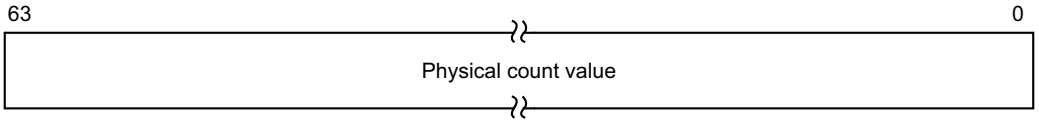
For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTPCT is a 64-bit register.

Field descriptions

The CNTPCT bit assignments are:



Bits [63:0]

Physical count value.

Accessing the CNTPCT:

CNTPCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame, as a RO register.

CNTBaseN describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTPCT is accessible in that frame, as a RO register, if the value of CNTACR<n>.RPCT is 1.
- Otherwise, the CNTPCT address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTPCT is accessible in that frame if both:
  - CNTPCT is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0PCTEN is 1.
- Otherwise, the CNTPCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CNTPCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x000	CNTPCT	31:0

This interface is accessible as follows:

- Accesses to CNTPCT[31:0] are RO.

CNTPCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x000	CNTPCT	31:0

This interface is accessible as follows:

- Accesses to CNTPCT[31:0] are RO.

CNTPCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x004	CNTPCT	63:32

This interface is accessible as follows:

- Accesses to CNTPCT[63:32] are RO.

CNTPCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x004	CNTPCT	63:32

This interface is accessible as follows:

- Accesses to CNTPCT[63:32] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.14 CNTSCR, Counter Scale Register

The CNTSCR characteristics are:

Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

Configurations

The power domain of CNTSCR is IMPLEMENTATION DEFINED.

Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

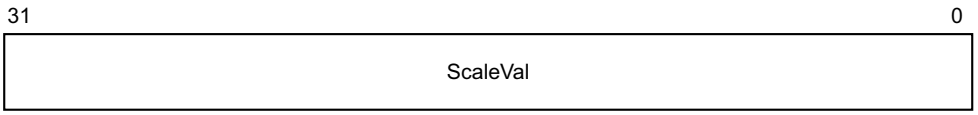
This register is present only when ARMv8.4-CNTSC is implemented. Otherwise, direct accesses to CNTSCR are RES0.

Attributes

CNTSCR is a 32-bit register.

Field descriptions

The CNTSCR bit assignments are:



ScaleVal, bits [31:0]

Scale Value

When counter scaling is enabled, ScaleVal is the amount added to the counter value for every counter tick.

Counter tick is defined as one period of the current operating frequency of the Generic counter.

ScaleVal is expressed as an unsigned fixed point number with an 8-bit integer value and a 24-bit fractional value.

CNTSCR.ScaleVal can only be changed when CNTCR.EN == 0. If the value of this field is changed when CNTCR.EN == 1:

- The counter value becomes UNKNOWN.
- The counter value remains UNKNOWN on future ticks of the clock.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTSCR:

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

CNTSCR can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x10	CNTSCR

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.15 CNTSR, Counter Status Register

The CNTSR characteristics are:

Purpose

Provides counter frequency status information.

Configurations

The power domain of CNTSR is IMPLEMENTATION DEFINED.

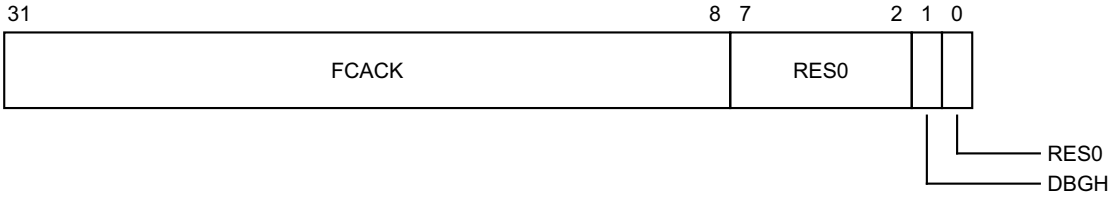
Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTSR is a 32-bit register.

Field descriptions

The CNTSR bit assignments are:



FCACK, bits [31:8]

Frequency change acknowledge. Indicates the currently selected entry in the Frequency modes table, see *The Frequency modes table* on page I2-7017.

This field resets to `0`.

Bits [7:2]

Reserved, RES0.

DBGH, bit [1]

Indicates whether the counter is halted because the Halt-on-debug signal is asserted:

`0b0` Counter is not halted.

`0b1` Counter is halted.

This field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

Accessing the CNTSR:

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CNTSR can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x004	CNTSR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.16 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

Purpose

Indicates the implemented timers in the memory map, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

Configurations

The power domain of CNTTIDR is IMPLEMENTATION DEFINED.

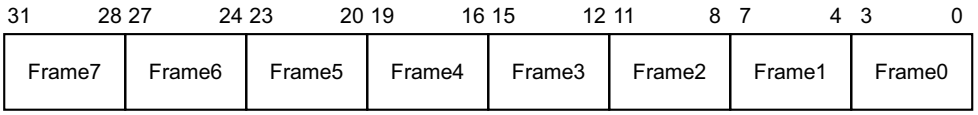
For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTTIDR is a 32-bit register.

Field descriptions

The CNTTIDR bit assignments are:



Frame<n>, bits [4n+3:4n], for n = 0 to 7

A 4-bit field indicating the features of frame CNTBase<n>.

Bit[3] of the field is RES0.

Bit[2], the FEL0 subfield, indicates whether frame CNTBase<n> has a second view, CNTEL0Base<n>. The possible values of this bit are:

Bit[2]	Meaning
0b0	Frame<n> does not have a second view. The CNTEL0ACR register in the first view of the frame is RES0
0b1	Frame<n> has a second view, CNTEL0Base<n>.

If bit[0] is 0, bit[2] is RES0.

Bit[1], the FVI subfield, indicates whether both:

- Frame CNTBase<n> implements the virtual timer registers CNTV_CVAL, CNTV_TVAL, and CNTV_CTL.
- This CNTCTLBase frame implements the virtual timer offset register CNTVOFF<n>.

The possible values of bit[1] are:

Bit[1]	Meaning
0b0	Frame<n> does not have virtual capability. The virtual time and offset registers are RES0.
0b1	Frame<n> has virtual capability. The virtual time and offset registers are implemented

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If bit[0] is 0, bit[1] is RES0.

Bit[0], the FI subfield, indicates whether frame CNTBase<n> is implemented. The possible values of this bit are:

Bit[0]	Meaning
0b0	Frame<n> is not implemented. All registers associated with the frame are RES0.
0b1	Frame<n> is implemented

Accessing the CNTTIDR:

In a system that recognizes two Security states this register is accessible by both Secure and Non-secure accesses.

CNTTIDR can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	0x008	CNTTIDR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.17 CNTV_CTL, Counter-timer Virtual Timer Control

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

Configurations

The power domain of CNTV_CTL is IMPLEMENTATION DEFINED.

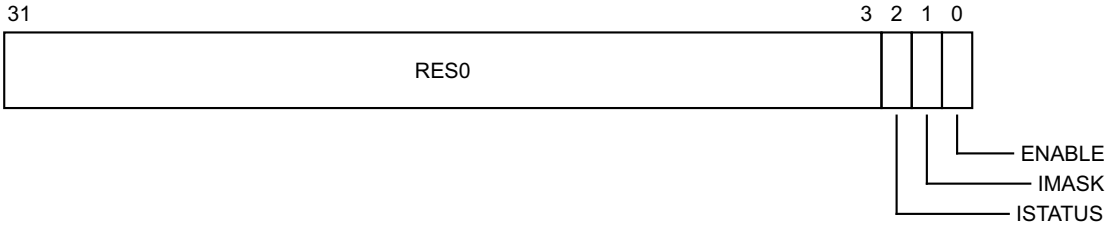
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

`0b0` Timer condition is not met.

`0b1` Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D11-2797 and *Operation of the TimerValue views of the timers* on page D11-2797.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0b0` Timer interrupt is not masked by the IMASK bit.

`0b1` Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0b0` Timer disabled.

`0b1` Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL continues to count down.

Note

Disabling the output signal might be a power-saving option.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_CTL:

CNTV_CTL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_CTL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_CTL is accessible in that frame if both:
  - CNTV_CTL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

CNTV_CTL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	`0x03C`	CNTV_CTL

This interface is accessible as follows:

- Accesses to this register are RW.

CNTV_CTL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	`0x03C`	CNTV_CTL

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.18 CNTV_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the virtual timer.

Configurations

The power domain of CNTV_CVAL is IMPLEMENTATION DEFINED.

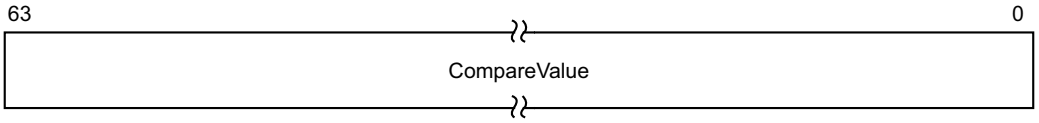
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:



CompareValue, bits [63:0]

Holds the virtual timer CompareValue.

When CNTV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- An interrupt is generated if CNTV_CTL.IMASK is 0.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_CVAL:

CNTV_CVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_CVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For an implemented CNTEL0BaseN frame:

- CNTV_CVAL is accessible in that frame if both:
  - CNTV_CVAL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTV_CVAL register must be accessible as an atomic 64-bit value.

CNTV_CVAL[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x030	CNTV_CVAL	31:0

This interface is accessible as follows:

- Accesses to CNTV_CVAL[31:0] are RW.

CNTV_CVAL[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x030	CNTV_CVAL	31:0

This interface is accessible as follows:

- Accesses to CNTV_CVAL[31:0] are RW.

CNTV_CVAL[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x034	CNTV_CVAL	63:32

This interface is accessible as follows:

- Accesses to CNTV_CVAL[63:32] are RW.

CNTV_CVAL[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x034	CNTV_CVAL	63:32

This interface is accessible as follows:

- Accesses to CNTV_CVAL[63:32] are RW.

I5.7.19 CNTV_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

Configurations

The power domain of CNTV_TVAL is IMPLEMENTATION DEFINED.

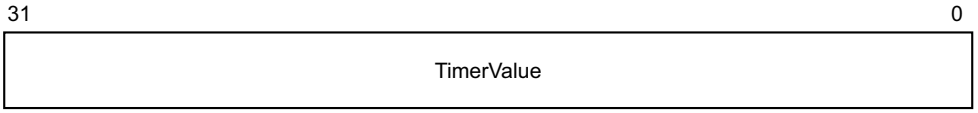
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:



TimerValue, bits [31:0]

The TimerValue view of the virtual timer.

On a read of this register:

- If CNTV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL.ENABLE is 1, the value returned is (CompareValue - CNTVCT).

On a write of this register, CompareValue is set to (CNTVCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTV_CTL.ENABLE is 1, the timer condition is met when (CNTVCT - CompareValue) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL.ISTATUS is set to 1.
- If CNTV_CTL.IMASK is 0, an interrupt is generated.

When CNTV_CTL.ENABLE is 0, the timer condition is not met, but CNTVCT continues to count, so the TimerValue view appears to continue to count down.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTV_TVAL:

CNTV_TVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_TVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_TVAL is accessible in that frame if both:
  - CNTV_TVAL is accessible in the corresponding CNTBaseN frame:
  - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

CNTV_TVAL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x038	CNTV_TVAL

This interface is accessible as follows:

- Accesses to this register are RW.

CNTV_TVAL can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0x038	CNTV_TVAL

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.20 CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value.

Configurations

The power domain of CNTVCT is IMPLEMENTATION DEFINED.

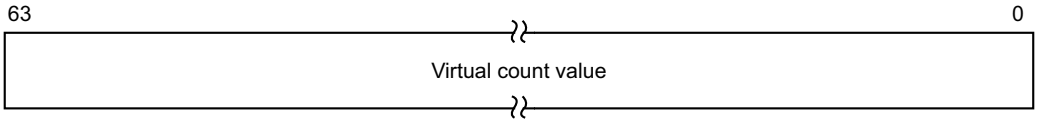
For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:



Bits [63:0]

Virtual count value.

Accessing the CNTVCT:

CNTVCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame, as a RO register.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTVCT is accessible in that frame, as a RO register, if the value of CNTACR<n>.RVCT is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTVCT is accessible in that frame if both:
  - CNTVCT is accessible in the corresponding CNTBaseN frame.
  - The value of CNTEL0ACR.EL0VCTEN is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTVCT register must be accessible as an atomic 64-bit value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CNTVCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x008	CNTVCT	31:0

This interface is accessible as follows:

- Accesses to CNTVCT[31:0] are RO.

CNTVCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x008	CNTVCT	31:0

This interface is accessible as follows:

- Accesses to CNTVCT[31:0] are RO.

CNTVCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x00C	CNTVCT	63:32

This interface is accessible as follows:

- Accesses to CNTVCT[63:32] are RO.

CNTVCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x00C	CNTVCT	63:32

This interface is accessible as follows:

- Accesses to CNTVCT[63:32] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.21 CNTVOFF, Counter-timer Virtual Offset

The CNTVOFF characteristics are:

Purpose

Holds the 64-bit virtual offset for a CNTBaseN frame that has virtual timer capability. This is the offset between real time and virtual time.

Configurations

The power domain of CNTVOFF is IMPLEMENTATION DEFINED.

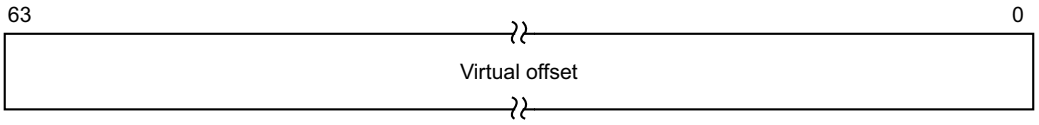
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTVOFF is a 64-bit register.

Field descriptions

The CNTVOFF bit assignments are:



Bits [63:0]

Virtual offset.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTVOFF:

CNTVOFF is implemented, as a RO register, in any implemented CNTBaseN frame that has virtual timer capability.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I2-7023 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTVOFF is accessible in that frame, as a RO register, if the value of CNTACR<n>.RVOFF is 1.
- Otherwise, the CNTVOFF address in that frame is RAZ/WI.

Note

CNTVOFF is never visible in any CNTEL0BaseN frame. This means that the CNTVOFF address in any implemented CNTEL0BaseN frame is RAZ/WI.

In an implementation that supports 64-bit atomic accesses, a CNTVOFF{<n>} register must be accessible as an atomic 64-bit value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CNTVOFF[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Range
Timer	CNTBaseN	0x018	31:0

This interface is accessible as follows:

- Accesses to CNTVOFF[31:0] are RO.

CNTVOFF[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Range
Timer	CNTBaseN	0x01C	63:32

This interface is accessible as follows:

- Accesses to CNTVOFF[63:32] are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.22 CNTVOFF<n>, Counter-timer Virtual Offsets, n = 0 - 7

The CNTVOFF<n> characteristics are:

Purpose

Holds the 64-bit virtual offset for frame CNTBase<n>. This is the offset between real time and virtual time.

Configurations

The implementation of CNTVOFF<n> is OPTIONAL.

The power domain of CNTVOFF<n> is IMPLEMENTATION DEFINED.

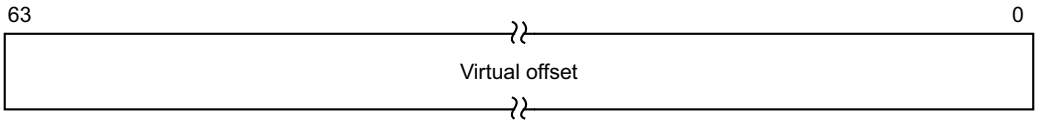
On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

Attributes

CNTVOFF<n> is a 64-bit register.

Field descriptions

The CNTVOFF<n> bit assignments are:



Bits [63:0]

Virtual offset.

This field resets to an architecturally UNKNOWN value.

Accessing the CNTVOFF<n>:

In the CNTCTLBase frame a CNTVOFF<n> register must be implemented, as a RW register, for each CNTBaseN frame that has virtual timer capability. For more information see *CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-7023.

Note

The value of <n> in an instance of CNTVOFF<n> specifies the value of N for the associated CNTBaseN frame.

In a system that recognizes two Security states, for any CNTVOFF<n> register in the CNTCTLBase frame:

- CNTVOFF<n> is always accessible by Secure accesses.
- CNTNSAR.NS<n> determines whether CNTVOFF<n> is accessible by Non-secure accesses.

The register location of any unimplemented CNTVOFF<n> register in the CNTCTLBase frame is RAZ/WI.

The CNTVOFF<n> register is accessible in the CNTBaseN frame using CNTVOFF.

In an implementation that supports 64-bit atomic accesses, then the CNTVOFF<n> registers must be accessible as atomic 64-bit values.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CNTVOFF<n>[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Range
Timer	CNTCTLBase	`0x080` + 8n	31:0

This interface is accessible as follows:

- Accesses to CNTVOFF<n>[31:0] are RW.

CNTVOFF<n>[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset	Range
Timer	CNTCTLBase	`0x084` + 8n	63:32

This interface is accessible as follows:

- Accesses to CNTVOFF<n>[63:32] are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.7.23 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

Purpose

IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.

Configurations

The power domain of CounterID<n> is IMPLEMENTATION DEFINED.

For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I2-7015.

These registers are implemented independently in each of the implemented Generic Timer memory-mapped frames.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the Arm Generic Timer is version 0.

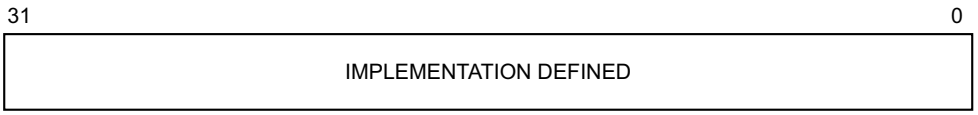
The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of `0xF`.

Attributes

CounterID<n> is a 32-bit register.

Field descriptions

The CounterID<n> bit assignments are:



IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the CounterID<n>:

These registers must be implemented, as RO registers, in every implemented Generic Timer memory-mapped frame.

For the CNTCTLBase frame, in a system that recognizes two Security states these registers are accessible by both Secure and Non-secure accesses.

For the CNTControlBase frame, in a system that supports Secure and Non-secure memory maps the frame is implemented only in the Secure memory map, meaning these registers are implemented only in the Secure memory map.

For the CNTBaseN frames, *CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames* on page I2-7023 describes the status fields that identify whether a frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CounterID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0xFD0 + 4n	CounterID<n>

This interface is accessible as follows:

- Accesses to this register are RO.

CounterID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTReadBase	0xFD0 + 4n	CounterID<n>

This interface is accessible as follows:

- Accesses to this register are RO.

CounterID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0xFD0 + 4n	CounterID<n>

This interface is accessible as follows:

- Accesses to this register are RO.

CounterID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0xFD0 + 4n	CounterID<n>

This interface is accessible as follows:

- Accesses to this register are RO.

CounterID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	0xFD0 + 4n	CounterID<n>

This interface is accessible as follows:

- Accesses to this register are RO.

Non-Confidential

I5.8 RAS Registers

This section describes the RAS registers.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.1 ERRCIDR0, Component Identification Register 0

The ERRCIDR0 characteristics are:

Purpose

Provides discovery information for the component.

Configurations

Implementation of this register is OPTIONAL.

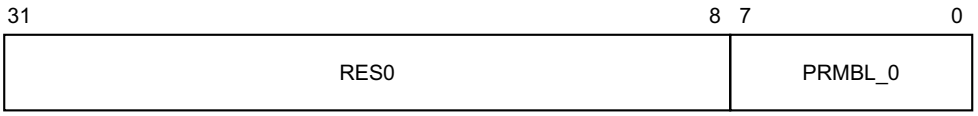
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRCIDR0 are RES0.

Attributes

ERRCIDR0 is a 32-bit register.

Field descriptions

The ERRCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Component identification preamble, segment 0. This field reads as `0x0D`.

Accessing the ERRCIDR0:

ERRCIDR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0xFF0`	ERRCIDR0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.2 ERRCIDR1, Component Identification Register 1

The ERRCIDR1 characteristics are:

Purpose

Provides discovery information for the component.

Configurations

Implementation of this register is OPTIONAL.

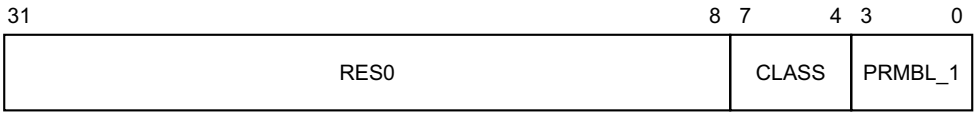
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRCIDR1 are RES0.

Attributes

ERRCIDR1 is a 32-bit register.

Field descriptions

The ERRCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class.

`0b1111` Generic peripheral with IMPLEMENTATION DEFINED register layout.

This field reads as `0xF`.

Other values are defined by the CoreSight Architecture.

PRMBL_1, bits [3:0]

Component identification preamble, segment 1. This field reads as `0x0`.

Accessing the ERRCIDR1:

ERRCIDR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0xFF4`	ERRCIDR1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.3 ERRCIDR2, Component Identification Register 2

The ERRCIDR2 characteristics are:

Purpose

Provides discovery information for the component.

Configurations

Implementation of this register is OPTIONAL.

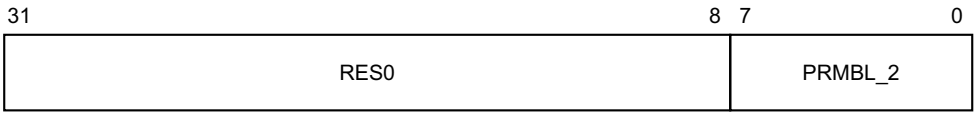
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRCIDR2 are RES0.

Attributes

ERRCIDR2 is a 32-bit register.

Field descriptions

The ERRCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Component identification preamble, segment 2. This field reads as `0x05`.

Accessing the ERRCIDR2:

ERRCIDR2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0xFF8`	ERRCIDR2

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.4 ERRCIDR3, Component Identification Register 3

The ERRCIDR3 characteristics are:

Purpose

Provides discovery information for the component.

Configurations

Implementation of this register is OPTIONAL.

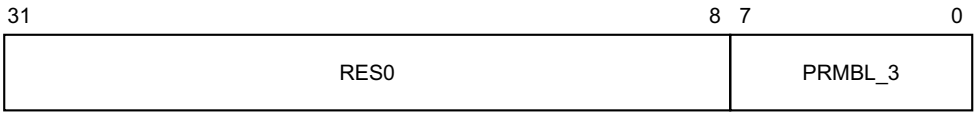
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRCIDR3 are RES0.

Attributes

ERRCIDR3 is a 32-bit register.

Field descriptions

The ERRCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Component identification preamble, segment 3. This field reads as `0xB1`.

Accessing the ERRCIDR3:

ERRCIDR3 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0xFFC`	ERRCIDR3

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.5 ERRCRICR0, Critical Error Interrupt Configuration Register 0

The ERRCRICR0 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRCRICR0 is architecturally mapped to External register ERRIRQCR<n>.

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERRCRICR0 are RES0.

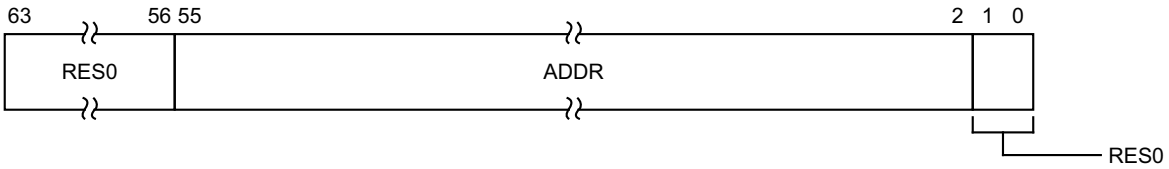
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRCRICR0 is a 64-bit register.

Field descriptions

The ERRCRICR0 bit assignments are:



Bits [63:56]

Reserved, RES0.

ADDR, bits [55:2]

Message Signaled Interrupt address.

Specifies the address that the component writes to when signaling an interrupt.

The size of a physical address is IMPLEMENTATION DEFINED. Unimplemented high-order physical address bits are RES0.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing the ERRCRICR0:

ERRCRICR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xEA0	ERRCRICR0

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.6 ERRCRICR1, Critical Error Interrupt Configuration Register 1

The ERRCRICR1 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRCRICR1[31:0] is architecturally mapped to External register ERRIRQCR<n>[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERRCRICR1 are RES0.

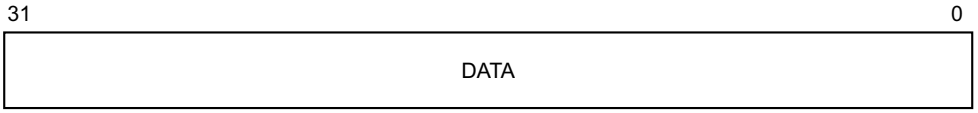
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRCRICR1 is a 32-bit register.

Field descriptions

The ERRCRICR1 bit assignments are:



DATA, bits [31:0]

Payload for a message signaled interrupt.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the ERRCRICR1:

ERRCRICR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xEA8	ERRCRICR1

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.7 ERRCRICR2, Critical Error Interrupt Configuration Register 2

The ERRCRICR2 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRCRICR2[31:0] is architecturally mapped to External register ERRIRQCR<n>[63:32].

Some or all RW fields of this register have defined reset values.

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERRCRICR2 are RES0.

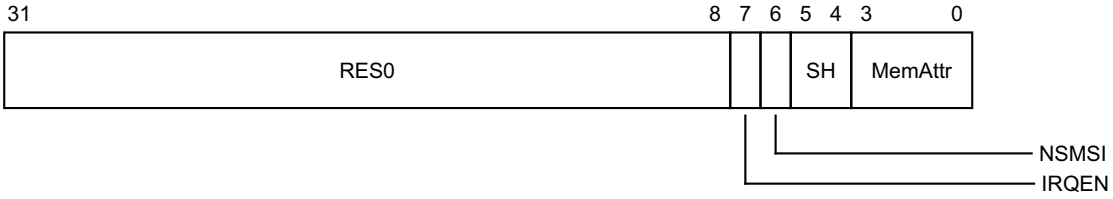
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRCRICR2 is a 32-bit register.

Field descriptions

The ERRCRICR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

IRQEN, bit [7]

Message Signaled Interrupt enable.

Enables generation of message signaled interrupts.

`0b0` Message signaled interrupts are disabled.

`0b1` Message signaled interrupts are enabled.

If the component does not support disabling message signaled interrupts, this bit is RES0.

The following resets apply:

- On a Error recovery reset, this field resets to `0`.
- On a Cold reset, this field resets to `0`.

NSMSI, bit [6]

Security attribute.

Defines the physical address space for message signaled interrupts.

`0b0` Physical address space for message signaled interrupts is Secure.

`0b1` Physical address space for message signaled interrupts is Non-secure.

If the component prohibits Non-secure writes and does not support configuring the Security attribute, then the Security attribute for message signaled interrupts is IMPLEMENTATION DEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the component allows Non-secure writes, then the Security attribute used for message signaled interrupts is Non-secure.

This bit is RES0 if any of the following are true:

- The component allows Non-secure writes.
- The component does not support configuring the Security attribute.

On a Cold reset, this field resets to an IMPLEMENTATION DEFINED value.

SH, bits [5:4]

Shareability.

Defines the Shareability domain for message signaled interrupts.

`0b00` Message signaled interrupts are in the Not shared Shareability domain.

`0b10` Message signaled interrupts are in the Outer Shareable Shareability domain.

`0b11` Message signaled interrupts are in the Inner Shareable Shareability domain.

If the component does not support configuring the Shareability domain, this field is RES0, meaning the Shareability domain for message signaled interrupts is IMPLEMENTATION DEFINED.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

MemAttr, bits [3:0]

Memory type.

Defines the memory type for message signaled interrupts. The values which correspond to each memory type are:

`0b0000` Device-nGnRnE.

`0b0001` Device-nGnRE.

`0b0010` Device-nGRE.

`0b0011` Device-GRE.

`0b0101` Outer Non-cacheable, Inner Non-cacheable.

`0b0110` Outer Non-cacheable, Inner Write-Through Cacheable.

`0b0111` Outer Non-cacheable, Inner Write-Back Cacheable.

`0b1001` Outer Write-Through Cacheable, Inner Non-cacheable.

`0b1010` Outer Write-Through Cacheable, Inner Write-Through Cacheable.

`0b1011` Outer Write-Through Cacheable, Inner Write-Back Cacheable.

`0b1101` Outer Write-Back Cacheable, Inner Non-cacheable.

`0b1110` Outer Write-Back Cacheable, Inner Write-Through Cacheable.

`0b1111` Outer Write-Back Cacheable, Inner Write-Back Cacheable.

If the component does not support configuring the memory type, this field is RES0, meaning the memory type used for message signaled interrupts is IMPLEMENTATION DEFINED.

Note

This is the same format as the VMSAv8-64 stage 2 memory region attributes.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the ERRCRICR2:

ERRCRICR2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xEAC	ERRCRICR2

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.8 ERRDEVAFF, Device Affinity Register

The ERRDEVAFF characteristics are:

Purpose

For a group that has affinity with a single PE or cluster of PEs, ERRDEVAFF is a copy of MPIDR_EL1 or part of MPIDR_EL1:

- If the group of error records has affinity with a single PE, the affinity level is 0, ERRDEVAFF reads the same value as MPIDR_EL1, and ERRDEVAFF.F0V reads-as-one to indicate affinity level 0.
- If the group of error records has affinity with a cluster of PEs, the affinity level is 1, 2, or 3, parts of ERRDEVAFF reads the same value as parts of MPIDR_EL1, and the rest of ERRDEVAFF indicates the level.

For example, if the affinity level is 2 then all of the following are true:

- The group of error records has affinity with all PEs in the system that have the same value in MPIDR_EL1.{Aff3,Aff2}.
- ERRDEVAFF.{Aff3,Aff2} reads the same value as MPIDR_EL1.{Aff3,Aff2}.
- ERRDEVAFF.Aff1 reads as `0x80` and ERRDEVAFF.{Aff0,F0V} read-as-zero, to indicate affinity level 2.

Configurations

Implementation of this register is OPTIONAL.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRDEVAFF are RES0.

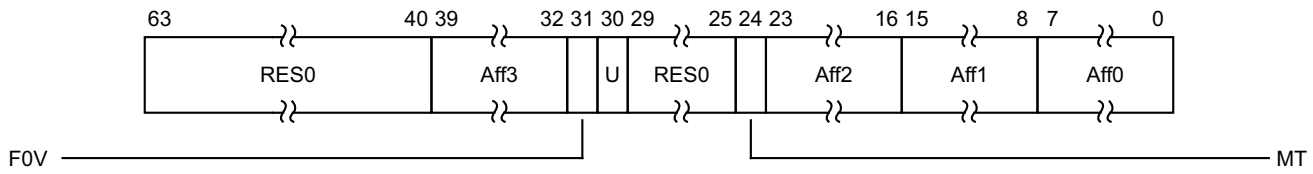
Present only if a group has affinity with a PE or cluster of PEs, and otherwise RES0.

Attributes

ERRDEVAFF is a 64-bit register.

Field descriptions

The ERRDEVAFF bit assignments are:



Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. The MPIDR_EL1.Aff3 field, viewed from the highest Exception level of the associated PE or PEs.

F0V, bit [31]

Indicates that the ERRDEVAFF.Aff0 field is valid.

`0b0` ERRDEVAFF.Aff0 is not valid, and the PE affinity level is 1, 2 or 3.

`0b1` ERRDEVAFF.Aff0 is valid, and the PE affinity level is 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

U, bit [30]

Uniprocessor. The MPIDR_EL1.U bit viewed from the highest Exception level of the associated PE.

`0b0` The PE is part of a multiprocessor system.

`0b1` The PE is part of a uniprocessor system.

If ERRDEVAFF.Aff0 is not valid, this bit is not valid and reads as UNKNOWN.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Multithreaded. The MPIDR_EL1.MT bit viewed from the highest Exception level of the associated PE.

`0b0` Performance of PEs at the lowest affinity level is largely independent.

`0b1` Performance of PEs at the lowest affinity level is very interdependent.

If ERRDEVAFF.Aff0 is not valid, this bit is not valid and reads as UNKNOWN.

Aff2, bits [23:16]

Affinity level 2.

When the PE affinity level is 0, 1, or 2, this field is the MPIDR_EL1.Aff2 field viewed from the highest Exception level of the associated PE or PEs.

When the PE affinity level is 3, this field indicates that ERRDEVAFF.Aff3 field is valid, and the following values are defined:

`0x80` ERRDEVAFF.Aff3 is valid, and the PE affinity level is 3.

This field reads as `0x80`.

All other values are reserved.

Aff1, bits [15:8]

Affinity level 1.

When the PE affinity level is 0 or 1, this field is the MPIDR_EL1.Aff1 field viewed from the highest Exception level of the associated PE or PEs.

When the PE affinity level is 2 or 3, this field indicates that ERRDEVAFF.Aff2 is valid, and the following values are defined:

`0x00` ERRDEVAFF.Aff2 is not valid, and the PE affinity level is 3.

`0x80` ERRDEVAFF.Aff2 is valid, and the PE affinity level is 2.

All other values are reserved.

Aff0, bits [7:0]

Affinity level 0.

When the PE affinity level is 0, this field is the MPIDR_EL1.Aff0 field viewed from the highest Exception level of the associated PE or PEs.

When the PE affinity level is 1, 2 or 3, this field indicates that ERRDEVAFF.Aff1 is valid, and the following values are defined:

`0x00` ERRDEVAFF.Aff1 is not valid, and the PE affinity level is 2 or 3.

`0x80` ERRDEVAFF.Aff1 is valid, and the PE affinity level is 1.

All other values are reserved.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the ERRDEVAFF:

ERRDEVAFF can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xFA8	ERRDEVAFF

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.9 ERRDEVARCH, Device Architecture Register

The ERRDEVARCH characteristics are:

Purpose

Provides discovery information for the component.

Configurations

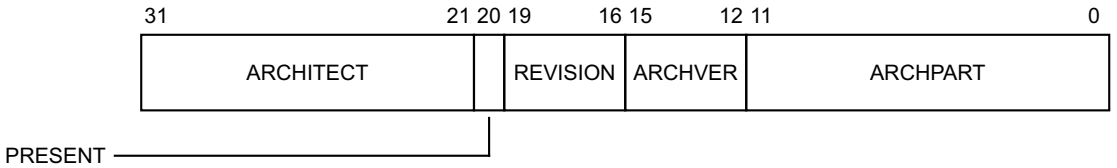
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRDEVARCH are UNDEFINED.

Attributes

ERRDEVARCH is a 32-bit register.

Field descriptions

The ERRDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Architect.

Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.

`0b01000111011` JEP106 continuation code `0x4`, ID code `0x3B`. Arm Limited.

This field reads as `0x23B`.

Other values are defined by the JEDEC JEP106 standard.

PRESENT, bit [20]

DEVARCH Present.

Defines that the DEVARCH register is present.

`0b0` Device Architecture information not present.

`0b1` Device Architecture information present.

This bit is RAO.

REVISION, bits [19:16]

Revision.

Defines the architecture revision of the component. The defined values of this field are:

`0b0000` RAS System Architecture v1.0.

`0b0001` RAS System Architecture v1.1. As `0b0000` and also:

- Simplifies ERR<n>STATUS.
- Adds support for additional ERR<n>MISC<m> registers.
- Adds support for the optional RAS Timestamp Extension.
- Adds support for the optional RAS Common Fault Injection Model Extension.

All other values are reserved.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ARCHVER, bits [15:12]

Architecture Version.

Defines the architecture version of the component. The defined values of this field are:

`0b0000` RAS System Architecture v1.

This field reads as `0b0000`.

All other values are reserved.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHVER is ARCHID[15:12].

ARCHPART, bits [11:0]

Architecture Part.

Defines the architecture of the component.

`0xA00` RAS system architecture.

This register reads as `0xA00`.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHPART is ARCHID[11:0].

Accessing the ERRDEVARCH:

ERRDEVARCH can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0xFBC`	ERRDEVARCH

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.10 ERRDEVID, Device Configuration Register

The ERRDEVID characteristics are:

Purpose

Provides discovery information for the component.

Configurations

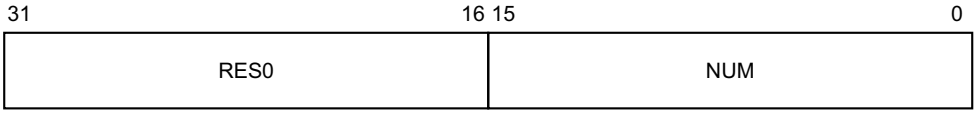
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRDEVID are UNDEFINED.

Attributes

ERRDEVID is a 32-bit register.

Field descriptions

The ERRDEVID bit assignments are:



Bits [31:16]

Reserved, RES0.

NUM, bits [15:0]

Highest numbered index of the error records in this group, plus one. Each implemented record is owned by a node. A node might own multiple records.

This manual describes the memory-mapped view of a group with up to 56 records, the most that can be contained in a 4KB component, meaning the highest possible value for this field is 56.

This field reads as an IMPLEMENTATION DEFINED value.

Accessing the ERRDEVID:

ERRDEVID can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xFC8	ERRDEVID

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.11 ERRERICR0, Error Recovery Interrupt Configuration Register 0

The ERRERICR0 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRERICR0 is architecturally mapped to External register ERRIRQCR<n>.

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRERICR0 are RES0.

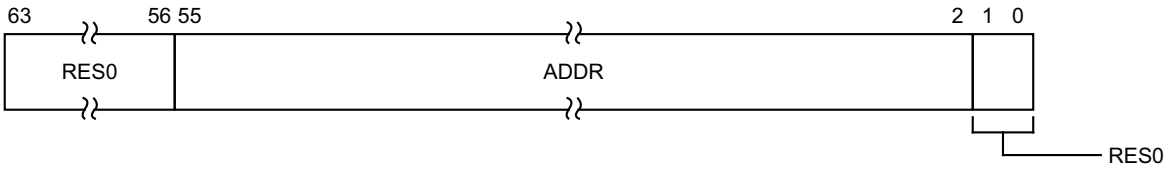
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRERICR0 is a 64-bit register.

Field descriptions

The ERRERICR0 bit assignments are:



Bits [63:56]

Reserved, RES0.

ADDR, bits [55:2]

Message Signaled Interrupt address.

Specifies the address that the component writes to when signaling an interrupt.

The size of a physical address is IMPLEMENTATION DEFINED. Unimplemented high-order physical address bits are RES0.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing the ERRERICR0:

ERRERICR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE90	ERRERICR0

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.12 ERRERICR1, Error Recovery Interrupt Configuration Register 1

The ERRERICR1 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRERICR1[31:0] is architecturally mapped to External register ERRIRQCR<n>[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRERICR1 are RES0.

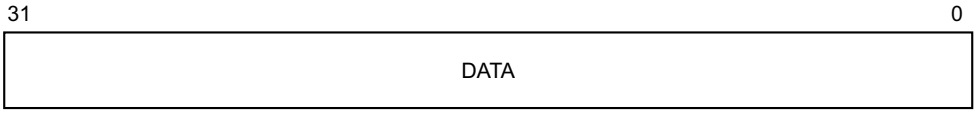
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRERICR1 is a 32-bit register.

Field descriptions

The ERRERICR1 bit assignments are:



DATA, bits [31:0]

Payload for a message signaled interrupt.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the ERRERICR1:

ERRERICR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE98	ERRERICR1

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.13 ERRERICR2, Error Recovery Interrupt Configuration Register 2

The ERRERICR2 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRERICR2[31:0] is architecturally mapped to External register ERRIRQCR<n>[63:32].

Some or all RW fields of this register have defined reset values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRERICR2 are RES0.

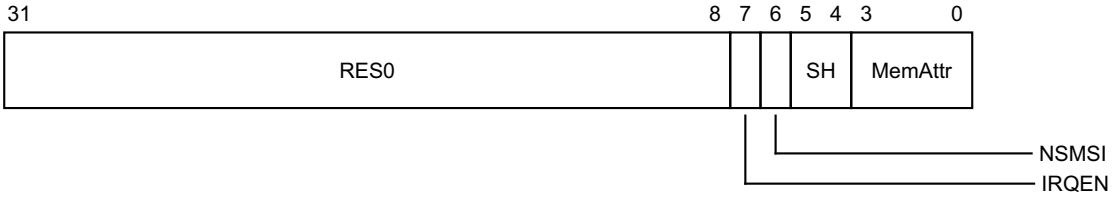
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRERICR2 is a 32-bit register.

Field descriptions

The ERRERICR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

IRQEN, bit [7]

Message Signaled Interrupt enable.

Enables generation of message signaled interrupts.

`0b0` Message signaled interrupts are disabled.

`0b1` Message signaled interrupts are enabled.

If the component does not support disabling message signaled interrupts, this bit is RES0.

The following resets apply:

- On a Error recovery reset, this field resets to `0`.
- On a Cold reset, this field resets to `0`.

NSMSI, bit [6]

Security attribute.

Defines the physical address space for message signaled interrupts.

`0b0` Physical address space for message signaled interrupts is Secure.

`0b1` Physical address space for message signaled interrupts is Non-secure.

If the component prohibits Non-secure writes and does not support configuring the Security attribute, then the Security attribute for message signaled interrupts is IMPLEMENTATION DEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the component allows Non-secure writes, then the Security attribute used for message signaled interrupts is Non-secure.

This bit is RES0 if any of the following are true:

- The component allows Non-secure writes.
- The component does not support configuring the Security attribute.

On a Cold reset, this field resets to an IMPLEMENTATION DEFINED value.

SH, bits [5:4]

Shareability.

Defines the Shareability domain for message signaled interrupts.

0b00 Message signaled interrupts are in the Not shared Shareability domain.

0b10 Message signaled interrupts are in the Outer Shareable Shareability domain.

0b11 Message signaled interrupts are in the Inner Shareable Shareability domain.

If the component does not support configuring the Shareability domain, this field is RES0, meaning the Shareability domain for message signaled interrupts is IMPLEMENTATION DEFINED.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

MemAttr, bits [3:0]

Memory type.

Defines the memory type for message signaled interrupts. The values which correspond to each memory type are:

0b0000 Device-nGnRnE.

0b0001 Device-nGnRE.

0b0010 Device-nGRE.

0b0011 Device-GRE.

0b0101 Outer Non-cacheable, Inner Non-cacheable.

0b0110 Outer Non-cacheable, Inner Write-Through Cacheable.

0b0111 Outer Non-cacheable, Inner Write-Back Cacheable.

0b1001 Outer Write-Through Cacheable, Inner Non-cacheable.

0b1010 Outer Write-Through Cacheable, Inner Write-Through Cacheable.

0b1011 Outer Write-Through Cacheable, Inner Write-Back Cacheable.

0b1101 Outer Write-Back Cacheable, Inner Non-cacheable.

0b1110 Outer Write-Back Cacheable, Inner Write-Through Cacheable.

0b1111 Outer Write-Back Cacheable, Inner Write-Back Cacheable.

If the component does not support configuring the memory type, this field is RES0, meaning the memory type used for message signaled interrupts is IMPLEMENTATION DEFINED.

Note

This is the same format as the VMSAv8-64 stage 2 memory region attributes.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the ERRERICR2:

ERRERICR2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE9C	ERRERICR2

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.14 ERRFHICR0, Fault-Handling Interrupt Configuration Register 0

The ERRFHICR0 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRFHICR0 is architecturally mapped to External register ERRIRQCR<n>.

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRFHICR0 are RES0.

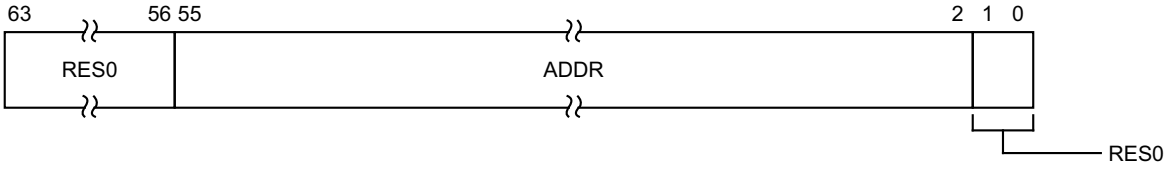
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRFHICR0 is a 64-bit register.

Field descriptions

The ERRFHICR0 bit assignments are:



Bits [63:56]

Reserved, RES0.

ADDR, bits [55:2]

Message Signaled Interrupt address.

Specifies the address that the component writes to when signaling an interrupt.

The size of a physical address is IMPLEMENTATION DEFINED. Unimplemented high-order physical address bits are RES0.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing the ERRFHICR0:

ERRFHICR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE80	ERRFHICR0

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.15 ERRFHICR1, Fault-Handling Interrupt Configuration Register 1

The ERRFHICR1 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRFHICR1[31:0] is architecturally mapped to External register ERRIRQCR<n>[31:0].

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRFHICR1 are RES0.

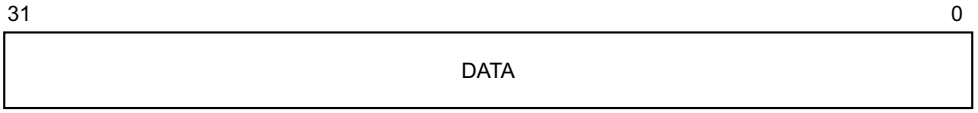
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRFHICR1 is a 32-bit register.

Field descriptions

The ERRFHICR1 bit assignments are:



DATA, bits [31:0]

Payload for a message signaled interrupt.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the ERRFHICR1:

ERRFHICR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE88	ERRFHICR1

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.16 ERRFHICR2, Fault-Handling Interrupt Configuration Register 2

The ERRFHICR2 characteristics are:

Purpose

Interrupt configuration register.

Configurations

External register ERRFHICR2[31:0] is architecturally mapped to External register ERRIRQCR<n>[63:32].

Some or all RW fields of this register have defined reset values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRFHICR2 are RES0.

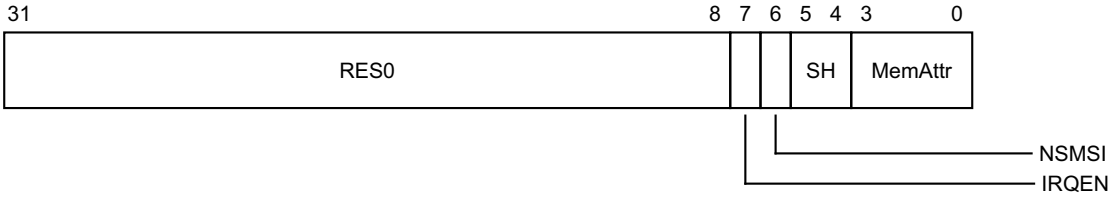
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRFHICR2 is a 32-bit register.

Field descriptions

The ERRFHICR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

IRQEN, bit [7]

Message Signaled Interrupt enable.

Enables generation of message signaled interrupts.

`0b0` Message signaled interrupts are disabled.

`0b1` Message signaled interrupts are enabled.

If the component does not support disabling message signaled interrupts, this bit is RES0.

The following resets apply:

- On a Error recovery reset, this field resets to `0`.
- On a Cold reset, this field resets to `0`.

NSMSI, bit [6]

Security attribute.

Defines the physical address space for message signaled interrupts.

`0b0` Physical address space for message signaled interrupts is Secure.

`0b1` Physical address space for message signaled interrupts is Non-secure.

If the component prohibits Non-secure writes and does not support configuring the Security attribute, then the Security attribute for message signaled interrupts is IMPLEMENTATION DEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the component allows Non-secure writes, then the Security attribute used for message signaled interrupts is Non-secure.

This bit is RES0 if any of the following are true:

- The component allows Non-secure writes.
- The component does not support configuring the Security attribute.

On a Cold reset, this field resets to an IMPLEMENTATION DEFINED value.

SH, bits [5:4]

Shareability.

Defines the Shareability domain for message signaled interrupts.

`0b00` Message signaled interrupts are in the Not shared Shareability domain.

`0b10` Message signaled interrupts are in the Outer Shareable Shareability domain.

`0b11` Message signaled interrupts are in the Inner Shareable Shareability domain.

If the component does not support configuring the Shareability domain, this field is RES0, meaning the Shareability domain for message signaled interrupts is IMPLEMENTATION DEFINED.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

MemAttr, bits [3:0]

Memory type.

Defines the memory type for message signaled interrupts. The values which correspond to each memory type are:

`0b0000` Device-nGnRnE.

`0b0001` Device-nGnRE.

`0b0010` Device-nGRE.

`0b0011` Device-GRE.

`0b0101` Outer Non-cacheable, Inner Non-cacheable.

`0b0110` Outer Non-cacheable, Inner Write-Through Cacheable.

`0b0111` Outer Non-cacheable, Inner Write-Back Cacheable.

`0b1001` Outer Write-Through Cacheable, Inner Non-cacheable.

`0b1010` Outer Write-Through Cacheable, Inner Write-Through Cacheable.

`0b1011` Outer Write-Through Cacheable, Inner Write-Back Cacheable.

`0b1101` Outer Write-Back Cacheable, Inner Non-cacheable.

`0b1110` Outer Write-Back Cacheable, Inner Write-Through Cacheable.

`0b1111` Outer Write-Back Cacheable, Inner Write-Back Cacheable.

If the component does not support configuring the memory type, this field is RES0, meaning the memory type used for message signaled interrupts is IMPLEMENTATION DEFINED.

Note

This is the same format as the VMSAv8-64 stage 2 memory region attributes.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the ERRFHICR2:

ERRFHICR2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE8C	ERRFHICR2

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.17 ERRGSR, Error Group Status Register

The ERRGSR characteristics are:

Purpose

ERRGSR shows the status for the records in the group.

Configurations

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRGSR are UNDEFINED.

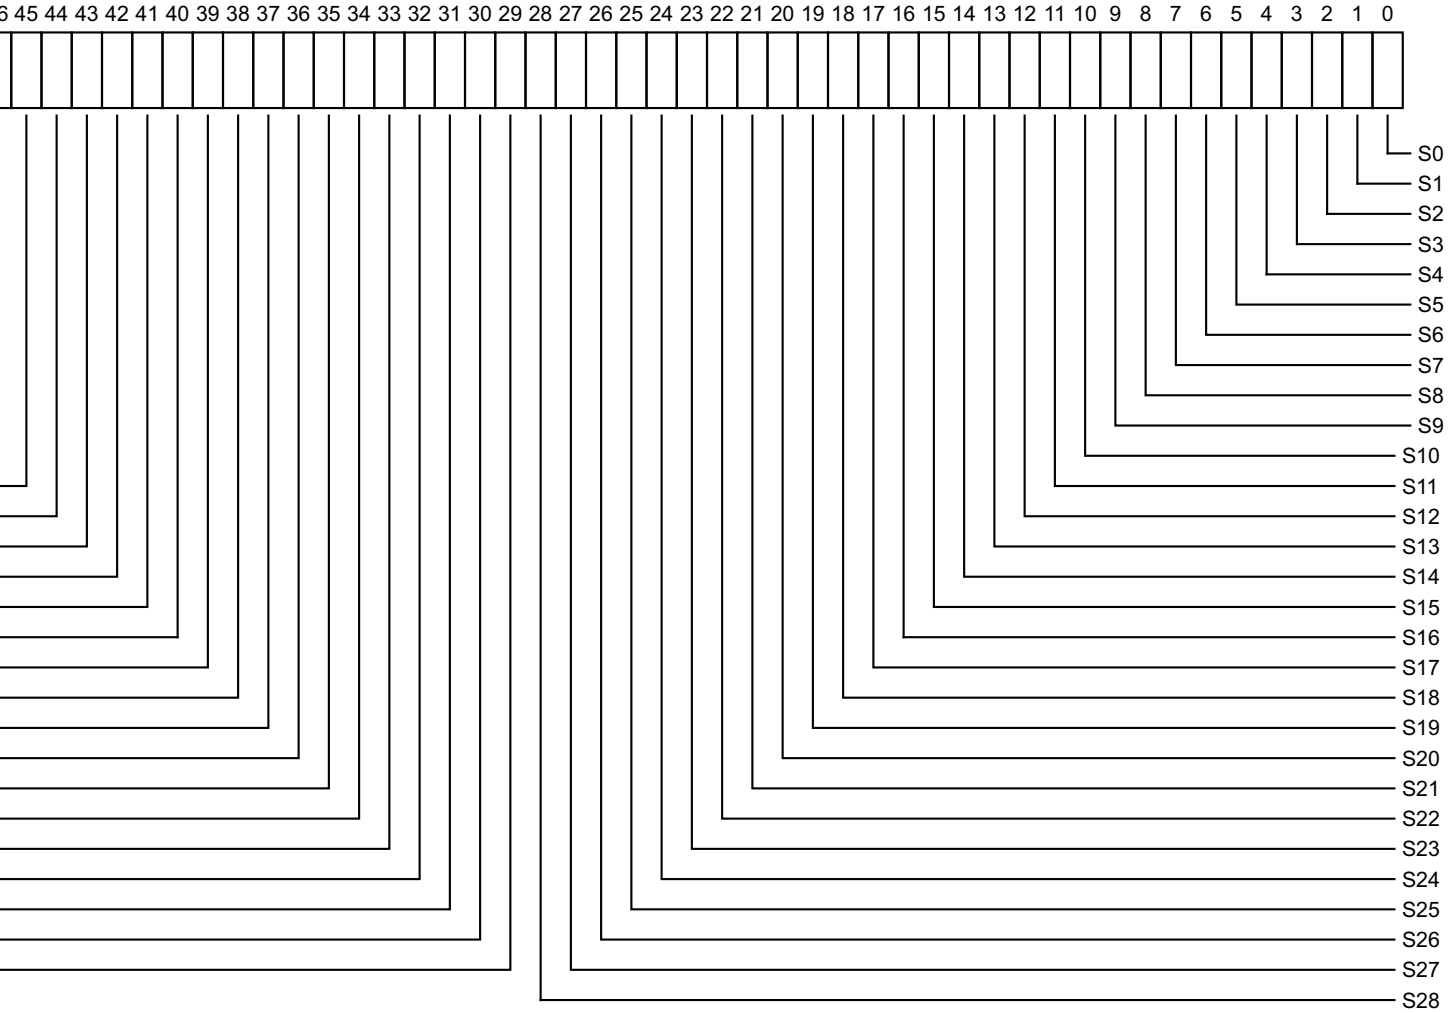
This manual describes the memory-mapped view of a group with up to 56 records, the most that can be contained in a 4KB component. Extra records might be added by increasing the page size and extending ERRGSR into multiple registers.

Attributes

ERRGSR is a 64-bit register.

Field descriptions

The ERRGSR bit assignments are:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [63:56]

Reserved, RES0.

S<m>, bit [m], for m = 0 to 55

The status for Error Record <m>. A read-only copy of ERR<n>STATUS.V.

0b0 No error.

0b1 One or more errors.

If the corresponding record is not implemented, or the corresponding record does not support this type of reporting, this bit is RES0.

Accessing the ERRGSR:

ERRGSR can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE00	ERRGSR

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.18 ERRIIDR, Implementation Identification Register

The ERRIIDR characteristics are:

Purpose

Defines the implementer of the component.

Configurations

Implementation of this register is OPTIONAL.

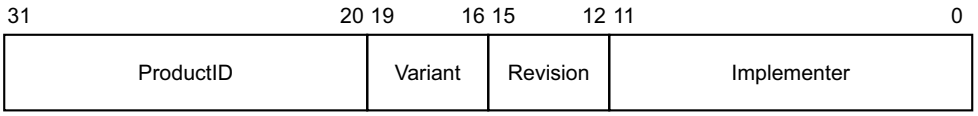
This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERRIIDR are RES0.

Attributes

ERRIIDR is a 32-bit register.

Field descriptions

The ERRIIDR bit assignments are:



ProductID, bits [31:20]

IMPLEMENTATION DEFINED.

Part number, bits [11:0]. The part number is selected by the designer of the component.

If ERRPIDR0 and ERRPIDR1 are implemented, ERRPIDR0.PART_0 matches bits [7:0] of ERRIIDR.ProductID and ERRPIDR1.PART_1 matches bits [11:8] of ERRIIDR.ProductID.

Variant, bits [19:16]

IMPLEMENTATION DEFINED.

Component major revision.

This field distinguishes product variants or major revisions of the product.

If ERRPIDR2 is implemented, ERRPIDR2.REVISION matches ERRIIDR.Variant.

Revision, bits [15:12]

IMPLEMENTATION DEFINED.

Component minor revision.

This field distinguishes minor revisions of the product.

If ERRPIDR3 is implemented, ERRPIDR3.REVAND matches ERRIIDR.Revision.

Implementer, bits [11:0]

IMPLEMENTATION DEFINED.

Contains the JEP106 code of the company that implemented the RAS component. For an Arm implementation, this field has the value `0x43B`.

Bits [11:8] contain the JEP106 continuation code of the implementer, and bits [6:0] contain the JEP106 identity code of the implementer. Bit 7 is RES0.

If ERRPIDR4 is implemented, ERRPIDR2 is implemented, and ERRPIDR1 is implemented, ERRPIDR4.DES_2 matches bits [11:8] of ERRIIDR.Implementer, ERRPIDR2.DES_1 matches bits [6:4] of ERRIIDR.Implementer, and ERRPIDR1.DES_0 matches bits [3:0] of ERRIIDR.Implementer.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the ERRIIDR:

ERRIIDR can be accessed through its memory-mapped interface:

Component	Offset
RAS	0xE10

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.19 ERRIRQCR<n>, Generic Error Interrupt Configuration Register, n = 0 - 15

The ERRIRQCR<n> characteristics are:

Purpose

The ERRIRQCR<n> registers are IMPLEMENTATION DEFINED interrupt configuration registers.

The architecture provides a recommended format for the ERRIRQCR<n> registers. The registers provided by the recommended layout are:

- ERRFHICR0, ERRFHICR1, and ERRFHICR2, the fault-handling interrupt configuration registers. ERRFHICR<m> maps to ERRIRQCR0 and ERRIRQCR1.
- ERRERICR0, ERRERICR1, and ERRERICR2, the error recovery interrupt configuration registers. ERRERICR<m> maps to ERRIRQCR2 and ERRIRQCR3.
- If ARMv8.4-RAS is implemented, ERRCRICR0, ERRCRICR1, and ERRCRICR2, the critical error interrupt configuration registers. ERRFHICR<m> maps to ERRIRQCR4 and ERRIRQCR5.
- ERRIRQSR, the error interrupt status register. ERRIRQSR maps to ERRIRQCR15.

This register describes the generic IMPLEMENTATION DEFINED format of the interrupt configuration registers, when the recommended layout is not used.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

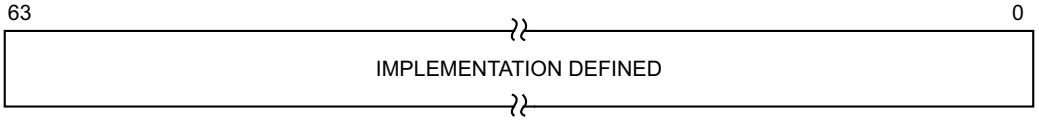
Present only if the interrupt configuration registers are implemented. Otherwise, this register is RES0.

Attributes

ERRIRQCR<n> is a 64-bit register.

Field descriptions

The ERRIRQCR<n> bit assignments are:



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED controls. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

Accessing the ERRIRQCR<n>:

ERRIRQCR<n> can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xE80 + 8n	ERRIRQCR<n>

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.20 ERRIRQSR, Error Interrupt Status Register

The ERRIRQSR characteristics are:

Purpose

Interrupt status register.

Configurations

External register ERRIRQSR is architecturally mapped to External register ERRIRQCR<n>.

RW fields in this register reset to architecturally UNKNOWN values.

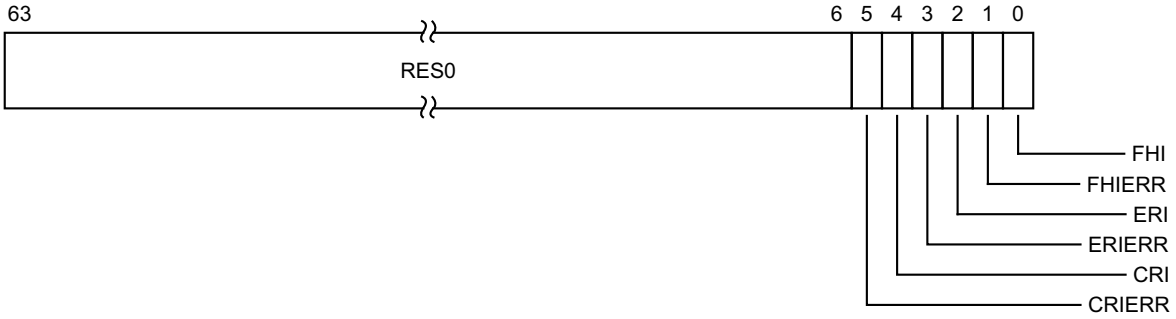
Present only if interrupt configuration registers use the recommended format. Otherwise, this register is RES0.

Attributes

ERRIRQSR is a 64-bit register.

Field descriptions

The ERRIRQSR bit assignments are:



Bits [63:6]

Reserved, RES0.

CRIERR, bit [5]

Critical error interrupt error.

`0b0` Interrupt write has not returned an error since this bit was last cleared to 0.

`0b1` Interrupt write has returned an error since this bit was last cleared to 0.

This bit is read/write-one-to-clear.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

CRI, bit [4]

Critical error interrupt write in progress.

`0b0` Interrupt write not in progress.

`0b1` Interrupt write in progress.

Software must not disable an interrupt whilst the write is in progress.

This bit is read-only.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This bit does not indicate whether an interrupt is active, but rather whether a write triggered by the interrupt is in progress.

To determine whether an interrupt is active, software must examine the individual ERR<n>STATUS registers.

ERIERR, bit [3]

Error recovery interrupt error.

0b0 Interrupt write has not returned an error since this bit was last cleared to 0.

0b1 Interrupt write has returned an error since this bit was last cleared to 0.

This bit read/write-one-to-clear.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ERI, bit [2]

Error recovery interrupt write in progress.

0b0 Interrupt write not in progress.

0b1 Interrupt write in progress.

Software must not disable an interrupt whilst the write is in progress.

This bit is read-only.

Note

This bit does not indicate whether an interrupt is active, but rather whether a write triggered by the interrupt is in progress.

To determine whether an interrupt is active, software must examine the individual ERR<n>STATUS registers.

FHIERR, bit [1]

Fault handling interrupt error.

0b0 Interrupt write has not returned an error since this bit was last cleared to 0.

0b1 Interrupt write has returned an error since this bit was last cleared to 0.

This bit read/write-one-to-clear.

The following resets apply:

- On a Error recovery reset, this field resets to an architecturally UNKNOWN value.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

FHI, bit [0]

Fault handling interrupt write in progress.

0b0 Interrupt write not in progress.

0b1 Interrupt write in progress.

Software must not disable an interrupt whilst the write is in progress.

This bit is read-only.

Note

This bit does not indicate whether an interrupt is active, but rather whether a write triggered by the interrupt is in progress.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

To determine whether an interrupt is active, software must examine the individual ERR<n>STATUS registers.

Accessing the ERRIRQSR:

ERRIRQSR can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xEF8	ERRIRQSR

I5.8.21 ERR<n>ADDR, Error Record Address Register, n = 0 - 65534

The ERR<n>ADDR characteristics are:

Purpose

If an error has an associated address, then this must be written to the address register when the error is recorded. It is IMPLEMENTATION DEFINED how the recorded addresses map to the software-visible physical addresses.

Software might have to reconstruct the actual physical addresses using the identity of the node and knowledge of the system.

Configurations

Some or all RW fields of this register have defined reset values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERR<n>ADDR are UNDEFINED.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If error record <n> is not implemented, ERR<n>ADDR is RES0.

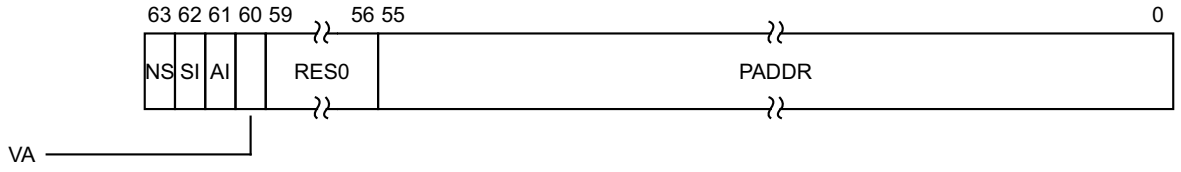
ERR<n>FR describes the features implemented by the node that owns error record <n>. <q> is the index of the first error record owned by the same node as error record <n>. If the node owns a single record, then q = n.

Attributes

ERR<n>ADDR is a 64-bit register.

Field descriptions

The ERR<n>ADDR bit assignments are:



NS, bit [63]

Non-secure attribute.

`0b0` The address is Secure.

`0b1` The address is Non-secure.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SI, bit [62]

Secure Incorrect.

Indicates whether the NS bit is valid.

`0b0` The NS bit is correct. That is, it matches the programmers' view of the Non-secure attribute for this recorded location.

`0b1` The NS bit might not be correct, and might not match the programmers' view of the Non-secure attribute for the recorded location.

It is IMPLEMENTATION DEFINED whether this bit is read-only or read/write.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

AI, bit [61]

Address Incorrect.

Indicates whether the PADDR field is a valid physical address that is known to match the programmers' view of the physical address for the recorded location.

`0b0` The PADDR field is a valid physical address. That is, it matches the programmers' view of the physical address for the recorded location.

`0b1` The PADDR field might not be a valid physical address, and might not match the programmers' view of the physical address for the recorded location.

It is IMPLEMENTATION DEFINED whether this bit is read-only or read/write.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

VA, bit [60]

Virtual Address.

Indicates whether the PADDR field is a virtual address.

`0b0` The PADDR field is not a virtual address.

`0b1` The PADDR field is a virtual address.

No context information is provided for the virtual address. When this bit is set to 1, ERR<n>ADDR.{NS,SI,AI} must read as {0,1,1}.

Support for this bit is optional. If this bit is not implemented and the PADDR field is a virtual address, then ERR<n>ADDR.{NS,SI,AI} must read as {0,1,1}.

It is IMPLEMENTATION DEFINED whether this bit is read-only or read/write.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [59:56]

Reserved, RES0.

PADDR, bits [55:0]

Physical Address. Address of the recorded location.

If the physical address size implemented by this component is smaller than the size of this field, then high-order bits are unimplemented and either RES0 or have a fixed read-only IMPLEMENTATION DEFINED value.

Low-order address bits might also be unimplemented and RES0, for example, if the physical address is always aligned to the size of a protection granule.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the ERR<n>ADDR:

ERR<n>ADDR ignores writes if ERR<n>STATUS.AV is set to 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ERR<n>ADDR can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0x018 + 64n	ERR<n>ADDR

This interface is accessible as follows:

- Accesses to this register are RW.

Non-Confidential

I5.8.22 ERR<n>CTLR, Error Record Control Register, n = 0 - 65534

The ERR<n>CTLR characteristics are:

Purpose

The error control register contains enable bits for the node that writes to this record, which:

- Enable error detection and correction.
- Enable an error recovery interrupt.
- Enable a fault handling interrupt.
- Enable error recovery reporting as a read or write error response.
- When ARMv.4-RAS is implemented, enable a critical error interrupt.

For each bit, if the selected node does not support the feature, then the bit is RES0. The definition of each record is IMPLEMENTATION DEFINED.

Configurations

Some or all RW fields of this register have defined reset values.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If error record <n> is not implemented, or error record <n> is not the first error record owned by the node, ERR<n>CTLR is RES0.

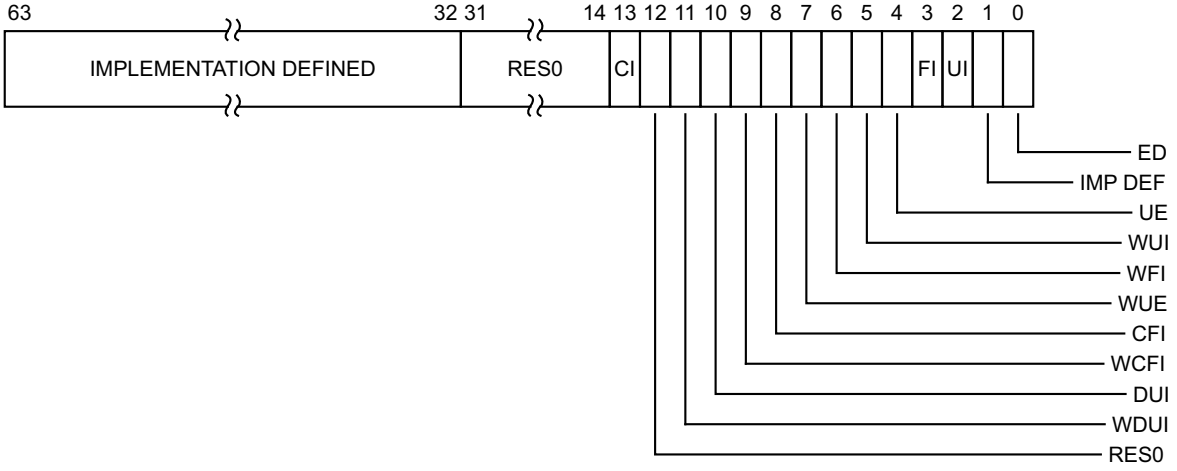
ERR<n>FR describes the features implemented by the node.

Attributes

ERR<n>CTLR is a 64-bit register.

Field descriptions

The ERR<n>CTLR bit assignments are:



IMPLEMENTATION DEFINED, bits [63:32]

IMPLEMENTATION DEFINED.

Reserved for IMPLEMENTATION DEFINED controls. Must permit SBZP write policy for software.

This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

Bits [31:14]

Reserved, RES0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CI, bit [13]

When ERR<n>FR.CI == 0b10:

Critical error interrupt enable.

When enabled, the critical error interrupt is generated for a critical error condition.

`0b0` Critical error interrupt not generated for critical errors. Critical errors are treated as Uncontained errors.

`0b1` Critical error interrupt generated for critical errors.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [12]

Reserved, RES0.

WDUI, bit [11]

When ERR<n>FR.DUI == 0b11:

Error recovery interrupt for deferred errors on writes enable.

When enabled, the error recovery interrupt is generated for all detected Deferred errors on writes.

`0b0` Error recovery interrupt not generated for deferred errors on writes.

`0b1` Error recovery interrupt generated for deferred errors on writes.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DUI, bit [10]

When ERR<n>FR.DUI == 0b10:

Error recovery interrupt for deferred errors enable. This control applies to errors arising from both reads and writes.

When enabled, an error recovery interrupt is generated for all detected Deferred errors.

`0b0` Error recovery interrupt not generated for deferred errors.

`0b1` Error recovery interrupt generated for deferred errors.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ERR<n>FR.DUI == 0b11:

When ERR<n>FR.DUI == `0b11`, this field is named RDUI.

Error recovery interrupt for deferred errors on reads enable.

When enabled, the error recovery interrupt is generated for all detected Deferred errors on reads.

`0b0` Error recovery interrupt not generated for deferred errors on reads.

`0b1` Error recovery interrupt generated for deferred errors on reads.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WCFI, bit [9]

When ERR<n>FR.CFI == 0b11:

Fault handling interrupt for Corrected errors on writes enable.

When enabled:

- If the node implements Corrected error counters, then the fault handling interrupt is generated when a counter overflows and the overflow bit for the counter is set to 1. For more information, see ERR<n>MISC0.
- Otherwise, the fault handling interrupt is also generated for all detected Corrected errors on writes.

`0b0` Fault handling interrupt not generated for Corrected errors on writes.

`0b1` Fault handling interrupt generated for Corrected errors on writes.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CFI, bit [8]

When ERR<n>FR.CFI == 0b10:

Fault handling interrupt for Corrected errors enable. This control applies to errors arising from both reads and writes.

When enabled:

- If the node implements Corrected error counters, then the fault handling interrupt is generated when a counter overflows and the overflow bit for the counter is set to 1. For more information, see ERR<n>MISC0.
- Otherwise, the fault handling interrupt is generated for all detected Corrected errors.

`0b0` Fault handling interrupt not generated for Corrected errors.

`0b1` Fault handling interrupt generated for Corrected errors.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ERR<n>FR.CFI == 0b11:

When ERR<n>FR.CFI == `0b11`, this field is named RCFI.

Fault handling interrupt for Corrected errors on reads enable.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When enabled:

- If the node implements Corrected error counters, then the fault handling interrupt is generated when a counter overflows and the overflow bit for the counter is set to 1. For more information, see ERR<n>MISC0.
- Otherwise, the fault handling interrupt is generated for all detected Corrected errors on reads.

`0b0` Fault handling interrupt not generated for Corrected errors on reads.

`0b1` Fault handling interrupt generated for Corrected errors on reads.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WUE, bit [7]

When ERR<n>FR.UE == 0b11:

In-band Uncorrected error reporting on writes enable.

When enabled, responses to writes that detect an Uncorrected error that cannot be deferred are signaled in-band as a detected Uncorrected error (External abort).

`0b0` External abort response for Uncorrected errors disabled for writes.

`0b1` External abort response for Uncorrected errors enabled for writes.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WFI, bit [6]

When ERR<n>FR.FI == 0b11:

Fault handling interrupt on writes enable.

When enabled:

- The fault handling interrupt is generated for all detected Deferred errors and Uncorrected errors on writes.
- If the fault handling interrupt for Corrected errors control is not implemented:
  - If the node implements Corrected error counters, then the fault handling interrupt is also generated when a counter overflows and the overflow bit for the counter is set to 1.
  - Otherwise, the fault handling interrupt is also generated for all detected Corrected errors on writes.

`0b0` Fault handling interrupt disabled on writes.

`0b1` Fault handling interrupt enabled on writes.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

WUI, bit [5]

When ERR<n>FR.UI == 0b11:

Uncorrected error recovery interrupt on writes enable.

When enabled, the error recovery interrupt is generated for all detected Uncorrected errors on writes that are not deferred.

`0b0` Error recovery interrupt disabled on writes.

`0b1` Error recovery interrupt enabled on writes.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UE, bit [4]

When ERR<n>FR.UE == 0b10:

In-band Uncorrected error reporting enable.

When enabled, responses to transactions that detect an Uncorrected error that cannot be deferred are signaled in-band as a detected Uncorrected error (External abort).

`0b0` External abort response for Uncorrected errors disabled.

`0b1` External abort response for Uncorrected errors enabled.

Note

This control applies to errors arising from both reads and writes.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ERR<n>FR.UE == 0b11:

When ERR<n>FR.UE == `0b11`, this field is named RUE.

In-band Uncorrected error reporting on reads enable.

When enabled, responses to reads that detect an Uncorrected error that cannot be deferred are signaled in-band as a detected Uncorrected error (External abort).

`0b0` External abort response for Uncorrected errors disabled for reads.

`0b1` External abort response for Uncorrected errors enabled for reads.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FI, bit [3]

When ERR<n>FR.FI == 0b10:

Fault handling interrupt enable. This control applies to errors arising from both reads and writes.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When enabled:

- The fault handling interrupt is generated for all detected Deferred errors and Uncorrected errors.
- If the fault handling interrupt for Corrected errors control is not implemented:
  - If the node implements Corrected error counters, then the fault handling interrupt is also generated when a counter overflows and the overflow bit for the counter is set to 1.
  - Otherwise, the fault handling interrupt is also generated for all detected Corrected errors.

`0b0` Fault handling interrupt disabled.

`0b1` Fault handling interrupt enabled.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ERR<n>FR.FI == 0b11:

When ERR<n>FR.FI == `0b11`, this field is named RFI.

Fault handling interrupt on reads enable.

When enabled:

- The fault handling interrupt is generated for all detected Deferred errors and Uncorrected errors on reads.
- If the fault handling interrupt for Corrected errors control is not implemented:
  - If the node implements Corrected error counters, then the fault handling interrupt is also generated when a counter overflows and the overflow bit for the counter is set to 1.
  - Otherwise, the fault handling interrupt is also generated for all detected Corrected errors on reads.

`0b0` Fault handling interrupt disabled on reads.

`0b1` Fault handling interrupt enabled on reads.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UI, bit [2]

When ERR<n>FR.UI == 0b10:

Uncorrected error recovery interrupt enable. This control applies to errors arising from both reads and writes.

When enabled, the error recovery interrupt is generated for all detected Uncorrected errors that are not deferred.

`0b0` Error recovery interrupt disabled.

`0b1` Error recovery interrupt enabled.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When ERR<n>FR.UI == 0b11:

When ERR<n>FR.UI == 0b11, this field is named RUI.

Uncorrected error recovery interrupt on reads enable.

When enabled, the error recovery interrupt is generated for all detected Uncorrected errors on reads that are not deferred.

0b0 Error recovery interrupt disabled on reads.

0b1 Error recovery interrupt enabled on reads.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IMPLEMENTATION DEFINED, bit [1]

IMPLEMENTATION DEFINED.

Reserved for IMPLEMENTATION DEFINED controls. Must permit SBZP write policy for software.

This bit reads as an IMPLEMENTATION DEFINED value and writes to this bit have IMPLEMENTATION DEFINED behavior.

ED, bit [0]

When ERR<n>FR.ED == 0b10:

Error reporting and logging enable.

When disabled, the node behaves as if error detection and correction are disabled, and no errors are recorded or signaled by the node. Arm recommends that, when disabled, correct error detection and correction codes are written for writes, unless disabled by an IMPLEMENTATION DEFINED control for error injection.

0b0 Error reporting disabled.

0b1 Error reporting enabled.

It is IMPLEMENTATION DEFINED whether the node fully disables error detection and correction when reporting is disabled. That is, even with error reporting disabled, the node might continue to silently correct errors. Uncorrectable errors might result in corrupt data being silently propagated by the node.

Note

If this node requires initialization after Cold reset to prevent signaling false errors, then Arm recommends this bit is set to 0 on Cold reset. This allows boot software to initialize a node without signaling errors. Software can enable error reporting after the node is initialized. If the Cold reset value is 1, the reset values of other controls in this register are IMPLEMENTATION DEFINED and should not be UNKNOWN.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:

Reserved, RES0.

I5.8.23 ERR<n>FR, Error Record Feature Register, n = 0 - 65534

The ERR<n>FR characteristics are:

Purpose

Defines whether <n> is the first record owned by a node. If <n> is the first record owned by the node, also defines which of the common architecturally-defined features are implemented by the node and, of the implemented features, which are software programmable.

Configurations

This register is present only when RAS is implemented. Otherwise, direct accesses to ERR<n>FR are RES0.

Present only if error record <n> is implemented. Otherwise, this register is RES0.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If <n> is the first error record owned by a node, then ERR<n>FR.ED != `0b00`.

If <n> is not the first error record owned by a node, then ERR<n>FR.ED == `0b00`.

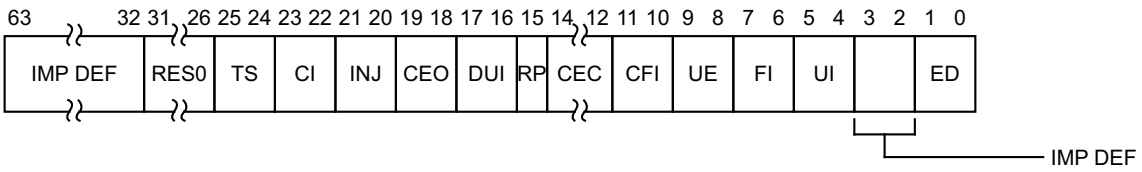
Attributes

ERR<n>FR is a 64-bit register.

Field descriptions

The ERR<n>FR bit assignments are:

When ERR<n>FR.ED != 0b00:



IMPLEMENTATION DEFINED, bits [63:32]

IMPLEMENTATION DEFINED.

Reserved for identifying IMPLEMENTATION DEFINED controls.

This field reads as an IMPLEMENTATION DEFINED value.

Bits [31:26]

Reserved, RES0.

TS, bits [25:24]

When ARMv8.4-RAS is implemented:

Timestamp Extension.

Indicates whether, for each error record <m> owned by this node, ERR<n>MISC3 is used as the timestamp register, and, if it is, the timebase used by the timestamp.

`0b00` The node does not support a timestamp register.

`0b01` The node implements a timestamp register. The timestamp uses the same timebase as the system Generic Timer.

Note

For an error record which has an affinity to a PE, this is the same timer that is visible through CNTPCT_EL0 at the highest Exception level on that PE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b10 The node implements a timestamp register. The timebase for the timestamp is IMPLEMENTATION DEFINED.

All other values are reserved.

Otherwise:

Reserved, RES0.

CI, bits [23:22]

Critical error interrupt.

Indicates whether the critical error interrupt and associated controls are implemented.

0b00 Does not support critical error interrupt.

0b01 Critical error interrupt is supported and is always enabled.

0b10 Critical error interrupt is supported and it can be enabled using associated controls.

All other values are reserved.

INJ, bits [21:20]

When ARMv8.4-RAS is implemented:

Fault Injection Extension.

Indicates whether the RAS Common Fault Injection Model Extension is implemented.

0b00 The node does not support the RAS Common Fault Injection Model Extension.

0b01 The node implements the RAS Common Fault Injection Model Extension. See ERR<n>PFGF for more information.

All other values are reserved.

Otherwise:

Reserved, RES0.

CEO, bits [19:18]

When ERR<n>FR.CEC != 0b00:

Corrected Error overwrite.

Indicates the behavior when a second Corrected error is detected after a first Corrected error has been recorded by an error record <m> owned by the node.

0b00 Counts Corrected errors if a counter is implemented. Keeps the previous error syndrome. If the counter overflows, or no counter is implemented, then ERR<n>STATUS.OF is set to 1.

0b01 Counts Corrected errors. If ERR<n>STATUS.OF == 1 before the Corrected error is counted, then keeps the previous syndrome. Otherwise, the previous syndrome is overwritten. If the counter overflows, then ERR<n>STATUS.OF is set to 1.

All other values are reserved.

Otherwise:

Reserved, RES0.

DUI, bits [17:16]

When ERR<n>FR.UI != 0b00:

Error recovery interrupt for deferred errors.

Indicates whether the node implements a control for enabling error recovery interrupts on deferred errors.

0b00 Does not support feature. ERR<n>CTLR.DUI is RES0.

0b10 Feature is controllable using ERR<n>CTLR.DUI.

0b11 Feature is controllable using ERR<n>CTLR.WDUI for writes and ERR<n>CTLR.RDUI for reads.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

Otherwise:

Reserved, RES0.

RP, bit [15]

When ERR<n>FR.CEC != 0b00:

Repeat counter.

Indicates whether the node implements a repeat Corrected error counter in ERR<n>MISC0 for each error record <m> owned by the node that implements a standard Corrected error counter.

`0b0` A single CE counter is implemented.

`0b1` A first (repeat) counter and a second (other) counter are implemented. The repeat counter is the same size as the primary error counter.

Otherwise:

Reserved, RES0.

CEC, bits [14:12]

Corrected Error Counter.

Indicates whether the node implements standard Corrected error counter (CE counter) mechanisms in ERR<n>MISC0 for each error record <m> owned by the node that can record countable errors.

`0b000` Does not implement the standard Corrected error counter model.

`0b010` Implements an 8-bit Corrected error counter in ERR<n>MISC0[39:32].

`0b100` Implements a 16-bit Corrected error counter in ERR<n>MISC0[47:32].

All other values are reserved.

Note

Implementations might include other error counter models, or might include the standard model and not indicate this in ERR<n>FR.

CFI, bits [11:10]

When ERR<n>FR.FI != 0b00:

Fault handling interrupt for corrected errors.

Indicates whether the node implements a control for enabling fault handling interrupts on corrected errors.

`0b00` Does not support feature. ERR<n>CTLR.CFI is RES0.

`0b10` Feature is controllable using ERR<n>CTLR.CFI.

`0b11` Feature is controllable using ERR<n>CTLR.WCFI for writes and ERR<n>CTLR.RCFI for reads.

All other values are reserved.

Otherwise:

Reserved, RES0.

UE, bits [9:8]

In-band uncorrected error reporting.

Indicates whether the node implements in-band uncorrected error reporting (External aborts), and, if so, whether the node implements controls for enabling and disabling the reporting.

`0b00` Does not support feature. ERR<n>CTLR.UE is RES0.

`0b01` Feature always enabled. ERR<n>CTLR.UE is RES0.

`0b10` Feature is controllable using ERR<n>CTLR.UE.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b11` Feature is controllable using ERR<n>CTLR.WUE for writes and ERR<n>CTLR.RUE for reads.

FI, bits [7:6]

Fault handling interrupt.

Indicates whether the node implements a fault handling interrupt, and, if so, whether the node implements controls for enabling and disabling the interrupt.

`0b00` Does not support feature. ERR<n>CTLR.FI is RES0.

`0b01` Feature always enabled. ERR<n>CTLR.FI is RES0.

`0b10` Feature is controllable using ERR<n>CTLR.FI.

`0b11` Feature is controllable using ERR<n>CTLR.WFI for writes and ERR<n>CTLR.RFI for reads.

UI, bits [5:4]

Error recovery interrupt for uncorrected errors.

Indicates whether the node implements an error recovery interrupt, and, if so, whether the node implements controls for enabling and disabling the interrupt.

`0b00` Does not support feature. ERR<n>CTLR.UI is RES0.

`0b01` Feature always enabled. ERR<n>CTLR.UI is RES0.

`0b10` Feature is controllable using ERR<n>CTLR.UI.

`0b11` Feature is controllable using ERR<n>CTLR.WUI for writes and ERR<n>CTLR.RUI for reads.

IMPLEMENTATION DEFINED, bits [3:2]

IMPLEMENTATION DEFINED.

This field reads as an IMPLEMENTATION DEFINED value.

ED, bits [1:0]

Error reporting and logging.

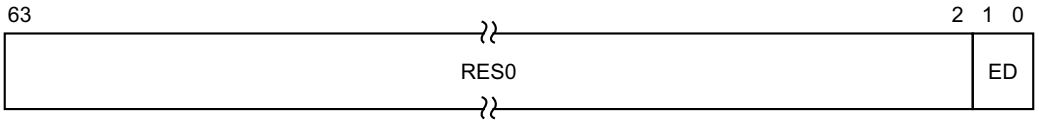
Indicates whether <n> is the first record owned by the node, and, if it is, whether the node implements controls for enabling and disabling error reporting and logging.

`0b01` Feature always enabled. ERR<n>CTLR.ED is RES0.

`0b10` Feature is controllable using ERR<n>CTLR.ED.

The value `0b11` is reserved.

When ERR<n>FR.ED == 0b00:



Bits [63:2]

Reserved, RES0.

ED, bits [1:0]

Error reporting and logging.

Indicates whether <n> is the first record owned by the node, and, if it is, whether the node implements controls for enabling and disabling error reporting and logging.

`0b00` Error record <n> is not the first record owned by the node.

I5.8.24 ERR<n>MISC0, Error Record Miscellaneous Register 0

The ERR<n>MISC0 characteristics are:

Purpose

IMPLEMENTATION DEFINED error syndrome register. The miscellaneous syndrome registers might contain:

- A Corrected error counter or counters.
- Information to identify the FRU in which the error was detected, and might contain enough information to locate the error within that FRU.
- Other state information not present in the corresponding status and address registers.

If the node <q> that owns error record <n> implements architecturally-defined error counters, so that ERR<n>FR.CEC != `0b000`, and error record <n> can record countable errors, then ERR<n>MISC0 implements the architecturally-defined error counter or counters.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

Some or all RW fields of this register have defined reset values.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If error record <n> is not implemented, ERR<n>MISC0 is RES0.

ERR<n>FR describes the features implemented by the node that owns error record <n>. <q> is the index of the first error record owned by the same node as error record <n>. If the node owns a single record, then q = n.

For IMPLEMENTATION DEFINED fields in this register, writing zero must always be supported to return the error record to an initial state.

In particular, if any IMPLEMENTATION DEFINED syndrome fields might generate a Fault Handling or Error Recovery Interrupt request, writing zero is sufficient to deactivate the Interrupt request.

Fields that are read-only, non-zero and ignore writes are compliant with this requirement.

Note

Arm recommends that any IMPLEMENTATION DEFINED syndrome fields that can generate a Fault Handling, Error Recovery, Critical, or IMPLEMENTATION DEFINED, interrupt request are disabled at Cold reset and are enabled by software writing an IMPLEMENTATION DEFINED non-zero value to an IMPLEMENTATION DEFINED field in ERR<q>CTRL, where q is the index of the first error record owned by the same node as error record n. If the node owns a single record then q = n.

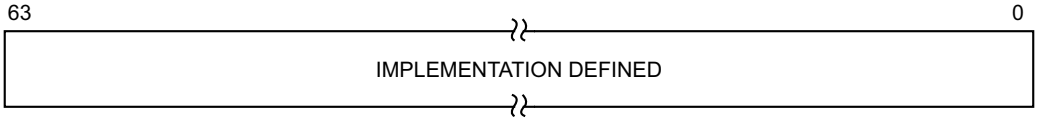
Attributes

ERR<n>MISC0 is a 64-bit register.

Field descriptions

The ERR<n>MISC0 bit assignments are:

When ERR<q>FR.CEC == 0b000:



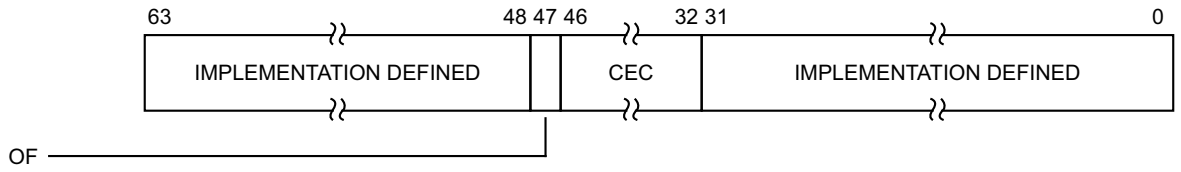
IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

When ERR<q>FR.CEC == 0b100 and ERR<q>FR.RP == 0:



IMPLEMENTATION DEFINED, bits [63:48]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

OF, bit [47]

Sticky overflow bit.

Set to 1 when the Corrected error count field is incremented and wraps through zero.

`0b0` Counter has not overflowed.

`0b1` Counter has overflowed.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

CEC, bits [46:32]

Corrected error count.

Incremented for each Corrected error. It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether Deferred and Uncorrected errors are counted.

The following resets apply:

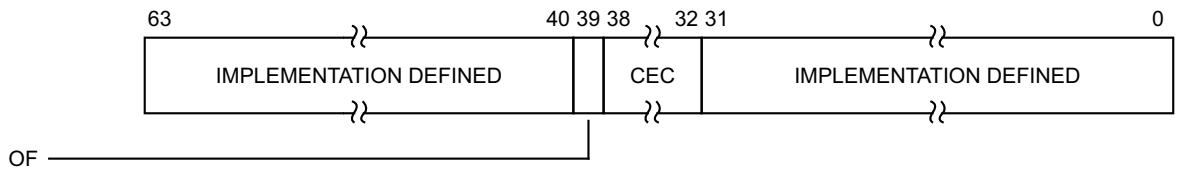
- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

When ERR<q>FR.CEC == 0b010 and ERR<q>FR.RP == 0:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMPLEMENTATION DEFINED, bits [63:40]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

OF, bit [39]

Sticky overflow bit.

Set to 1 when the Corrected error count field is incremented and wraps through zero.

`0b0` Counter has not overflowed.

`0b1` Counter has overflowed.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

CEC, bits [38:32]

Corrected error count.

Incremented for each Corrected error. It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether Deferred and Uncorrected errors are counted.

The following resets apply:

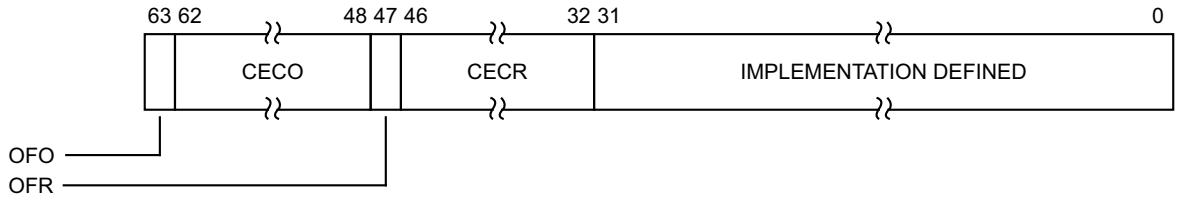
- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

When ERR<q>FR.CEC == 0b100 and ERR<q>FR.RP == 1:



OFO, bit [63]

Sticky overflow bit, other.

Set to 1 when the Corrected error count, other, field is incremented and wraps through zero.

`0b0` Other counter has not overflowed.

`0b1` Other counter has overflowed.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CECO, bits [62:48]

Corrected error count, other.

Incremented for each countable error that is not accounted for by incrementing ERR<n>MISC0.CECR.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

OFR, bit [47]

Sticky overflow bit, repeat.

Set to 1 when the Corrected error count, repeat, field is incremented and wraps through zero.

`0b0` Repeat counter has not overflowed.

`0b1` Repeat counter has overflowed.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

CECR, bits [46:32]

Corrected error count, repeat.

Incremented for the first countable error, which also records other syndrome for the error, and subsequently for each countable error that matches the recorded other syndrome. Corrected errors are countable errors. It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether Deferred and Uncorrected errors are countable errors.

Note

For example, the other syndrome might include the set and way information for an error detected in a cache. This might be recorded in the IMPLEMENTATION DEFINED ERR<n>MISC<m> fields on a first Corrected error. ERR<n>MISC0.CECR is then incremented for each subsequent Corrected Error in the same set and way.

The following resets apply:

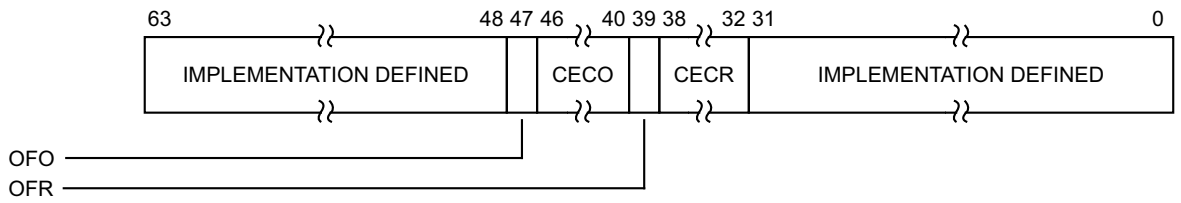
- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

When ERR<q>FR.CEC == 0b010 and ERR<q>FR.RP == 1:



Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMPLEMENTATION DEFINED, bits [63:48]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

OFO, bit [47]

Sticky overflow bit, other.

Set to 1 when the Corrected error count, other, field is incremented and wraps through zero.

`0b0` Other counter has not overflowed.

`0b1` Other counter has overflowed.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

CECO, bits [46:40]

Corrected error count, other.

Incremented for each countable error that is not accounted for by incrementing ERR<n>MISC0.CECR.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

OFR, bit [39]

Sticky overflow bit, repeat.

Set to 1 when the Corrected error count, repeat, field is incremented and wraps through zero.

`0b0` Repeat counter has not overflowed.

`0b1` Repeat counter has overflowed.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

CECR, bits [38:32]

Corrected error count, repeat.

Incremented for the first countable error, which also records other syndrome for the error, and subsequently for each countable error that matches the recorded other syndrome. Corrected errors are countable errors. It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether Deferred and Uncorrected errors are countable errors.

Note

For example, the other syndrome might include the set and way information for an error detected in a cache. This might be recorded in the IMPLEMENTATION DEFINED ERR<n>MISC<m> fields on a first Corrected error. ERR<n>MISC0.CECR is then incremented for each subsequent Corrected Error in the same set and way.

The following resets apply:

- This field is preserved on an Error Recovery reset.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

Accessing the ERR<n>MISC0:

Arm recommends that a miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write.

When ERR<n>STATUS.MV is set to 1, the miscellaneous syndrome for the most recently recorded error should ignore writes.

ERR<n>MISC0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0x020` + 64n	ERR<n>MISC0

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.25 ERR<n>MISC1, Error Record Miscellaneous Register 1, n = 0 - 65534

The ERR<n>MISC1 characteristics are:

Purpose

IMPLEMENTATION DEFINED error syndrome register. The miscellaneous syndrome registers can contain:

- A Corrected error counter or counters.
- Information to identify the FRU in which the error was detected, and might contain enough information to locate the error within that FRU.
- Other state information not present in the corresponding status and address registers.

Configurations

This register is present only when RAS is implemented. Otherwise, direct accesses to ERR<n>MISC1 are UNDEFINED.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If error record <n> is not implemented, ERR<n>MISC1 is RES0.

ERR<n>FR describes the features implemented by the node that owns error record <n>. <q> is the index of the first error record owned by the same node as error record <n>. If the node owns a single record, then q = n.

For IMPLEMENTATION DEFINED fields in this register, writing zero must always be supported to return the error record to an initial state.

In particular, if any IMPLEMENTATION DEFINED syndrome fields might generate a Fault Handling or Error Recovery Interrupt request, writing zero is sufficient to deactivate the Interrupt request.

Fields that are read-only, non-zero and ignore writes are compliant with this requirement.

Note

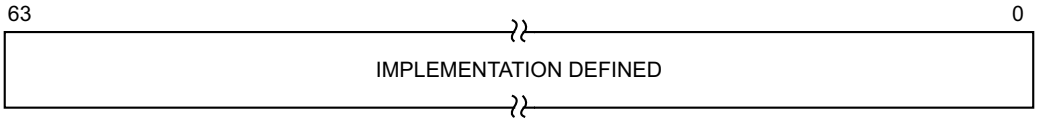
Arm recommends that any IMPLEMENTATION DEFINED syndrome fields that can generate a Fault Handling, Error Recovery, Critical, or IMPLEMENTATION DEFINED, interrupt request are disabled at Cold reset and are enabled by software writing an IMPLEMENTATION DEFINED non-zero value to an IMPLEMENTATION DEFINED field in ERR<q>CTRL, where q is the index of the first error record owned by the same node as error record n. If the node owns a single record then q = n.

Attributes

ERR<n>MISC1 is a 64-bit register.

Field descriptions

The ERR<n>MISC1 bit assignments are:



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

Accessing the ERR<n>MISC1:

Arm recommends that a miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

When ERR<n>STATUS.MV is set to 1, the miscellaneous syndrome for the most recently recorded error should ignore writes.

ERR<n>MISC1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0x028 + 64n	ERR<n>MISC1

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.26 ERR<n>MISC2, Error Record Miscellaneous Register 2, n = 0 - 65534

The ERR<n>MISC2 characteristics are:

Purpose

IMPLEMENTATION DEFINED error syndrome register. The miscellaneous syndrome registers can contain:

- A Corrected error counter or counters.
- Information to identify the FRU in which the error was detected, and might contain enough information to locate the error within that FRU.
- Other state information not present in the corresponding status and address registers.

Configurations

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERR<n>MISC2 are RES0.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If error record <n> is not implemented, ERR<n>MISC2 is RES0.

ERR<n>FR describes the features implemented by the node that owns error record <n>. <q> is the index of the first error record owned by the same node as error record <n>. If the node owns a single record, then q = n.

For IMPLEMENTATION DEFINED fields in this register, writing zero must always be supported to return the error record to an initial state.

In particular, if any IMPLEMENTATION DEFINED syndrome fields might generate a Fault Handling or Error Recovery Interrupt request, writing zero is sufficient to deactivate the Interrupt request.

Fields that are read-only, non-zero and ignore writes are compliant with this requirement.

Note

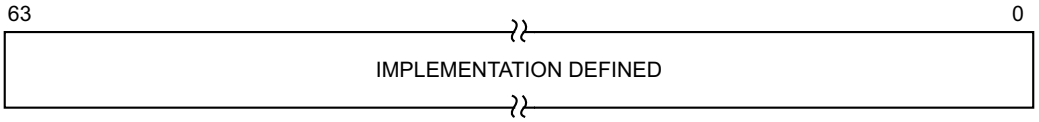
Arm recommends that any IMPLEMENTATION DEFINED syndrome fields that can generate a Fault Handling, Error Recovery, Critical, or IMPLEMENTATION DEFINED, interrupt request are disabled at Cold reset and are enabled by software writing an IMPLEMENTATION DEFINED non-zero value to an IMPLEMENTATION DEFINED field in ERR<q>CTRL, where q is the index of the first error record owned by the same node as error record n. If the node owns a single record then q = n.

Attributes

ERR<n>MISC2 is a 64-bit register.

Field descriptions

The ERR<n>MISC2 bit assignments are:



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

Accessing the ERR<n>MISC2:

Arm recommends that a miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write.

Non-Confidential

When ERR<n>STATUS.MV is set to 1, the miscellaneous syndrome for the most recently recorded error should ignore writes.

ERR<n>MISC2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0x030 + 64n	ERR<n>MISC2

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.27 ERR<n>MISC3, Error Record Miscellaneous Register 3, n = 0 - 65534

The ERR<n>MISC3 characteristics are:

Purpose

IMPLEMENTATION DEFINED error syndrome register. The miscellaneous syndrome registers can contain:

- A Corrected error counter or counters.
- Information to identify the FRU in which the error was detected, and might contain enough information to locate the error within that FRU.
- Other state information not present in the corresponding status and address registers.

If the node <q> that owns error record <n> supports the RAS Timestamp Extension, then ERR<n>MISC3 contains the timestamp value for error record <n> when the error was detected. Otherwise the contents of ERR<n>MISC3 are IMPLEMENTATION DEFINED.

Configurations

External register ERR<n>MISC3 is architecturally mapped to AArch64 System register ERXMISC3_EL1 when ERRSELR_EL1.SEL == n.

External register ERR<n>MISC3[31:0] is architecturally mapped to AArch32 System register ERXMISC6[31:0] when ERRSELR_EL1.SEL == n.

External register ERR<n>MISC3[63:32] is architecturally mapped to AArch32 System register ERXMISC7[31:0] when ERRSELR_EL1.SEL == n.

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERR<n>MISC3 are RES0.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If error record <n> is not implemented, ERR<n>MISC3 is RES0.

ERR<n>FR describes the features implemented by the node that owns error record <n>. <q> is the index of the first error record owned by the same node as error record <n>. If the node owns a single record, then q = n.

For IMPLEMENTATION DEFINED fields in this register, writing zero must always be supported to return the error record to an initial state.

In particular, if any IMPLEMENTATION DEFINED syndrome fields might generate a Fault Handling or Error Recovery Interrupt request, writing zero is sufficient to deactivate the Interrupt request.

Fields that are read-only, non-zero and ignore writes are compliant with this requirement.

Note

Arm recommends that any IMPLEMENTATION DEFINED syndrome fields that can generate a Fault Handling, Error Recovery, Critical, or IMPLEMENTATION DEFINED, interrupt request are disabled at Cold reset and are enabled by software writing an IMPLEMENTATION DEFINED non-zero value to an IMPLEMENTATION DEFINED field in ERR<q>CTRL, where q is the index of the first error record owned by the same node as error record n. If the node owns a single record then q = n.

Attributes

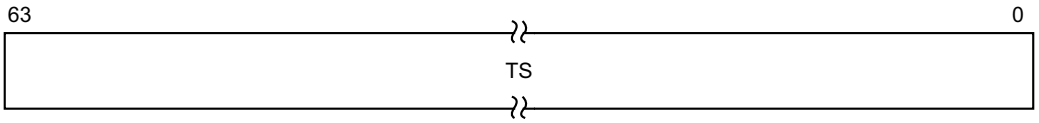
ERR<n>MISC3 is a 64-bit register.

Field descriptions

The ERR<n>MISC3 bit assignments are:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When ERR<q>FR.TS != 0b00:



TS, bits [63:0]

Timestamp.

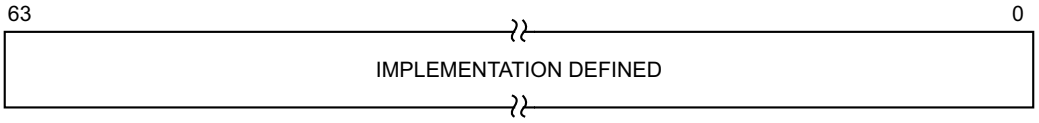
Timestamp value recorded when the error was detected. Valid only if ERR<n>STATUS.V == 1.

See ERR<n>FR.TS.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO or RW.

When ERR<q>FR.TS == 0b00:



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED syndrome. This field reads as an IMPLEMENTATION DEFINED value and writes to this field have IMPLEMENTATION DEFINED behavior.

Accessing the ERR<n>MISC3:

Arm recommends that a miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write.

When ERR<n>STATUS.MV is set to 1, the miscellaneous syndrome for the most recently recorded error should ignore writes.

ERR<n>MISC3 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0x038` + 64n	ERR<n>MISC3

This interface is accessible as follows:

- Accesses to this register are RW.

Non-Confidential

I5.8.28 ERR<n>PFGCDN, Pseudo-fault Generation Countdown Register, n = 0 - 65534

The ERR<n>PFGCDN characteristics are:

Purpose

Generates one of the errors enabled in the corresponding ERR<n>PFGCTL register.

For details of this, see the *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile*.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERR<n>PFGCDN are RES0.

Present only when the RAS Common Fault Injection Model Extension is implemented by this node so that ERR<n>FR.INJ != `0b00`, error record <n> is implemented, and error record <n> is the first error record owned by a node. Otherwise, RES0.

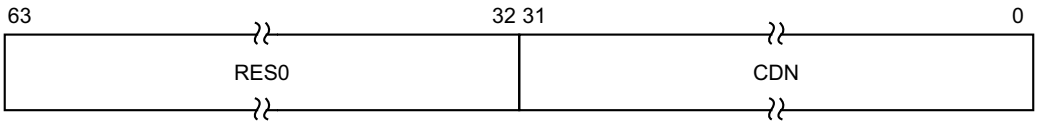
ERR<n>FR describes the features implemented by the node.

Attributes

ERR<n>PFGCDN is a 64-bit register.

Field descriptions

The ERR<n>PFGCDN bit assignments are:



Bits [63:32]

Reserved, RES0.

CDN, bits [31:0]

Countdown value.

This field is copied to Error Generation Counter when either:

- Software writes ERR<n>PFGCTL.CDNEN with 1.
- The Error Generation Counter decrements to zero and ERR<n>PFGCTL.R == 1.

While ERR<n>PFGCTL.CDNEN == 1 and the Error Generation Counter is nonzero, the counter decrements by 1 for each cycle at an IMPLEMENTATION DEFINED clock rate. When the counter reaches 0, one of the errors enabled in the ERR<n>PFGCTL register is generated.

Note

The current Error Generation Counter value is not visible to software.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the ERR<n>PFGCDN:

ERR<n>PFGCDN can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0x810 + 64n	ERR<n>PFGCDN

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.29 ERR<n>PFGCTL, Pseudo-fault Generation Control Register, n = 0 - 65534

The ERR<n>PFGCTL characteristics are:

Purpose

Enables controlled fault generation.

Configurations

Some or all RW fields of this register have defined reset values.

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERR<n>PFGCTL are RES0.

Present only when the RAS Common Fault Injection Model Extension is implemented by this node so that ERR<n>FR.INJ != 0b00, error record <n> is implemented, and error record <n> is the first error record owned by a node. Otherwise, RES0.

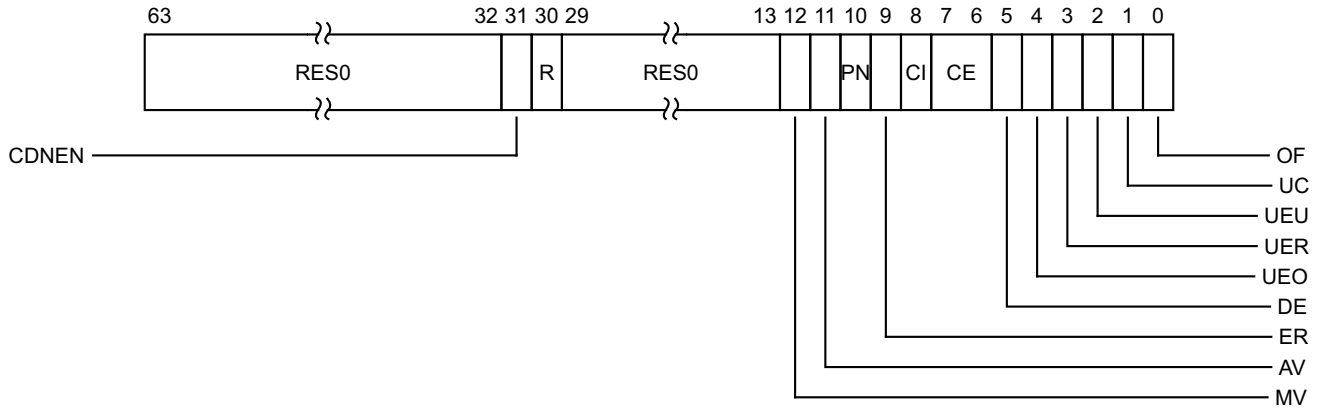
ERR<n>FR describes the features implemented by the node.

Attributes

ERR<n>PFGCTL is a 64-bit register.

Field descriptions

The ERR<n>PFGCTL bit assignments are:



Bits [63:32]

Reserved, RES0.

CDNEN, bit [31]

Countdown Enable. Controls transfers from the value that is held in the ERR<n>PFGCDN into the Error Generation Counter, and enables this counter.

0b0 The Error Generation Counter is disabled.

0b1 The Error Generation Counter is enabled. On a write of 1 to this bit, the Error Generation Counter is set to ERR<n>PFGCDN.CDN.

On a Cold reset, this field resets to 0.

R, bit [30]

Restart. Controls whether, on reaching zero, the Error Generation Counter restarts from the ERR<n>PFGCDN value, or stops.

0b0 On reaching 0, the Error Generation Counter stops.

0b1 On reaching 0, the Error Generation Counter is set to ERR<n>PFGCDN.CDN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [29:13]

Reserved, RES0.

MV, bit [12]

Miscellaneous syndrome. The value that is written to ERR<n>STATUS.MV when an injected error is recorded.

0b0 ERR<n>STATUS.MV is set to 0 when an injected error is recorded.

0b1 ERR<n>STATUS.MV is set to 1 when an injected error is recorded.

This bit reads-as-one if the node always records some syndrome in ERR<n>MISC<m>, setting ERR<n>STATUS.MV to 1, when an injected error is recorded.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

AV, bit [11]

Address syndrome. The value that is written to ERR<n>STATUS.AV when an injected error is recorded.

0b0 ERR<n>STATUS.AV is set to 0 when an injected error is recorded.

0b1 ERR<n>STATUS.AV is set to 1 when an injected error is recorded,

This bit reads-as-one if the node always sets ERR<n>STATUS.AV to 1 when an injected error is recorded.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

PN, bit [10]

Poison flag. The value that is written to ERR<n>STATUS.PN when an injected error is recorded.

0b0 ERR<n>STATUS.PN is set to 0 when an injected error is recorded.

0b1 ERR<n>STATUS.PN is set to 1 when an injected error is recorded.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

ER, bit [9]

Error Reported flag. The value that is written to ERR<n>STATUS.ER when an injected error is recorded.

0b0 ERR<n>STATUS.ER is set to 0 when an injected error is recorded.

0b1 ERR<n>STATUS.ER is set to 1 when an injected error is recorded.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

CI, bit [8]

Critical Error flag. The value that is written to ERR<n>STATUS.CI when an injected error is recorded.

0b0 ERR<n>STATUS.CI is set to 0 when an injected error is recorded.

0b1 ERR<n>STATUS.CI is set to 1 when an injected error is recorded.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CE, bits [7:6]

Corrected Error generation enable. Controls the type of Corrected Error condition that might be generated.

`0b00` No error of this type is generated.

`0b01` A non-specific Corrected Error, that is, a Corrected Error that is recorded as ERR<n>STATUS.CE == `0b10`, might be generated when the Error Generation Counter decrements to zero.

`0b10` A transient Corrected Error, that is, a Corrected Error that is recorded as ERR<n>STATUS.CE == `0b01`, might be generated when the Error Generation Counter decrements to zero.

`0b11` A persistent Corrected Error, that is, a Corrected Error that is recorded as ERR<n>STATUS.CE == `0b11`, might be generated when the Error Generation Counter decrements to zero.

The set of permitted values for this field is defined by ERR<n>PFGF.CE.

This field is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

DE, bit [5]

Deferred Error generation enable. Controls whether this type of error condition might be generated. It is IMPLEMENTATION DEFINED whether the error is generated if the data is not consumed.

`0b0` No error of this type is generated.

`0b1` An error of this type might be generated when the Error Generation Counter decrements to zero.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

UEO, bit [4]

Latent or Restartable Error generation enable. Controls whether this type of error condition might be generated. It is IMPLEMENTATION DEFINED whether the error is generated if the data is not consumed.

`0b0` No error of this type is generated.

`0b1` An error of this type might be generated when the Error Generation Counter decrements to zero.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

UER, bit [3]

Signaled or Recoverable Error generation enable. Controls whether this type of error condition might be generated. It is IMPLEMENTATION DEFINED whether the error is generated if the data is not consumed.

`0b0` No error of this type is generated.

`0b1` An error of this type might be generated when the Error Generation Counter decrements to zero.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

UEU, bit [2]

Unrecoverable Error generation enable. Controls whether this type of error condition might be generated. It is IMPLEMENTATION DEFINED whether the error is generated if the data is not consumed.

`0b0` No error of this type is generated.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1 An error of this type might be generated when the Error Generation Counter decrements to zero.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

UC, bit [1]

Uncontainable Error generation enable. Controls whether this type of error condition might be generated. It is IMPLEMENTATION DEFINED whether the error is generated if the data is not consumed.

0b0 No error of this type is generated.

0b1 An error of this type might be generated when the Error Generation Counter decrements to zero.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

OF, bit [0]

Overflow flag. The value that is written to ERR<n>STATUS.OF when an injected error is recorded.

0b0 ERR<n>STATUS.OF is set to 0 when an injected error is recorded.

0b1 ERR<n>STATUS.OF is set to 1 when an injected error is recorded.

This bit is RES0 if the node does not support this control.

On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the ERR<n>PFGCTL:

ERR<n>PFGCTL can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0x808 + 64n	ERR<n>PFGCTL

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.30 ERR<n>PFGF, Pseudo-fault Generation Feature Register, n = 0 - 65534

The ERR<n>PFGF characteristics are:

Purpose

Defines which common architecturally-defined fault generation features are implemented.

Configurations

This register is present only when ARMv8.4-RAS is implemented. Otherwise, direct accesses to ERR<n>PFGF are RES0.

Present only when the RAS Common Fault Injection Model Extension is implemented by this node so that ERR<n>FR.INJ != `0b00`, error record <n> is implemented, and error record <n> is the first error record owned by a node. Otherwise, RES0.

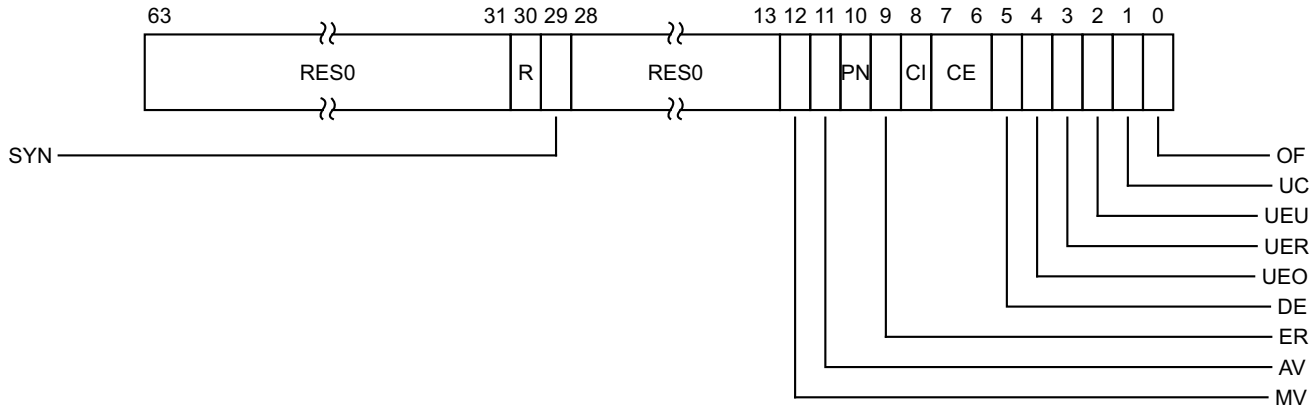
ERR<n>FR describes the features implemented by the node.

Attributes

ERR<n>PFGF is a 64-bit register.

Field descriptions

The ERR<n>PFGF bit assignments are:



Bits [63:31]

Reserved, RES0.

R, bit [30]

Restartable. Support for Error Generation Counter restart mode.

`0b0` The node does not support this feature.

`0b1` Feature controllable.

SYN, bit [29]

Syndrome. Fault syndrome injection.

`0b0` When an injected error is recorded, the node sets ERR<n>STATUS.{IERR, SERR} to IMPLEMENTATION DEFINED values. ERR<n>STATUS.{IERR, SERR} are UNKNOWN when ERR<n>STATUS.V == 0.

`0b1` When an injected error is recorded, the node does not update the ERR<n>STATUS.{IERR, SERR} fields. ERR<n>STATUS.{IERR, SERR} are writable when ERR<n>STATUS.V == 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If this bit is 1, software can write specific values into the ERR<n>STATUS.{IERR, SERR} fields when setting up a fault injection event. The sets of values that can be written to these fields is IMPLEMENTATION DEFINED.

Bits [28:13]

Reserved, RES0.

MV, bit [12]

Miscellaneous syndrome.

Additional syndrome injection. Defines whether software can control all or part of the syndrome recorded in the ERR<n>MISC<m> registers when an injected error is recorded.

It is IMPLEMENTATION DEFINED which syndrome fields in ERR<n>MISC<m> this refers to, as some fields might always be recorded by an error. For example, a Corrected Error counter.

`0b0` When an injected error is recorded, the node might record IMPLEMENTATION DEFINED additional syndrome in ERR<n>MISC<m>. If any syndrome is recorded in ERR<n>MISC<m>, ERR<n>STATUS.MV is set to 1.

`0b1` When an injected error is recorded, the node does not update all the syndrome fields in the ERR<n>MISC<m> and does one of:

- The node does not update any fields in ERR<n>MISC<m> and sets ERR<n>STATUS.MV to ERR<n>PFGCTL.MV.
- The node records some syndrome in ERR<n>MISC<m> and sets ERR<n>STATUS.MV to 1. ERR<n>PGFCTL.MV is RAO.

The syndrome fields that the node does not update are unchanged and must be writable when ERR<n>STATUS.MV is set to 0.

Note

If this bit is 1, software can write specific values into the ERR<n>MISC<m> registers when setting up a fault injection event. The values that can be written to these registers are IMPLEMENTATION DEFINED.

AV, bit [11]

Address syndrome. Address syndrome injection.

`0b0` When an injected error is recorded, the node either sets ERR<n>ADDR and ERR<n>STATUS.AV for the access, or leaves these unchanged.

`0b1` When an injected error is recorded, the node does not update ERR<n>ADDR and does one of:

- Sets ERR<n>STATUS.AV to ERR<n>PFGCTL.AV.
- Sets ERR<n>STATUS.AV to 1. ERR<n>PFGCTL.AV is RAO. ERR<n>ADDR must be writable when ERR<n>STATUS.AV is set to 0.

Note

If this bit is 1, software can write a specific value into ERR<n>ADDR when setting up a fault injection event.

PN, bit [10]

Poison flag. Describes how the fault generation feature of the node sets the ERR<n>STATUS.PN status flag.

`0b0` When an injected error is recorded, it is IMPLEMENTATION DEFINED whether the node sets ERR<n>STATUS.PN to 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` When an injected error is recorded, ERR<n>STATUS.PN is set to ERR<n>PFGCTL.PN.

This behavior replaces the architecture-defined rules for setting the PN bit.

This bit reads-as-zero if the node does not support this flag.

ER, bit [9]

Error Reported flag. Describes how the fault generation feature of the node sets the ERR<n>STATUS.ER status flag.

`0b0` When an injected error is recorded, the node sets ERR<n>STATUS.ER according to the architecture-defined rules for setting the ER bit.

`0b1` When an injected error is recorded, ERR<n>STATUS.ER is set to ERR<n>PFGCTL.ER.

This behavior replaces the architecture-defined rules for setting the ER bit.

This bit reads-as-zero if the node does not support this flag.

CI, bit [8]

Critical Error flag. Describes how the fault generation feature of the node sets the ERR<n>STATUS.CI status flag.

`0b0` When an injected error is recorded, it is IMPLEMENTATION DEFINED whether the node sets ERR<n>STATUS.CI to 1.

`0b1` When an injected error is recorded, ERR<n>STATUS.CI is set to ERR<n>PFGCTL.CI.

This behavior replaces the architecture-defined rules for setting the CI bit.

This bit reads-as-zero if the node does not support this flag.

CE, bits [7:6]

Corrected Error generation. Describes the types of Corrected Error that the fault generation feature of the node can generate.

`0b00` The fault generation feature of the node cannot generate this type of error.

`0b01` The fault generation feature of the node allows generation of a non-specific Corrected Error, that is, a Corrected Error that is recorded as ERR<n>STATUS.CE == `0b10`.

`0b11` The fault generation feature of the node allows generation of transient or persistent Corrected Errors, that is, Corrected Errors that are recorded as ERR<n>STATUS.CE == `0b01` and `0b11`.

All other values are reserved.

This bit reads-as-zero if the node does not support this type of error.

DE, bit [5]

Deferred Error generation. Describes whether the fault generation feature of the node can generate this type of error.

`0b0` The fault generation feature of the node cannot generate this type of error.

`0b1` The fault generation feature of the node allows generation of this type of error.

This bit reads-as-zero if the node does not support this type of error.

UEO, bit [4]

Latent or Restartable Error generation. Describes whether the fault generation feature of the node can generate this type of error.

`0b0` The fault generation feature of the node cannot generate this type of error.

`0b1` The fault generation feature of the node allows generation of this type of error.

This bit reads-as-zero if the node does not support this type of error.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

UER, bit [3]

Signaled or Recoverable Error generation. Describes whether the fault generation feature of the node can generate this type of error.

`0b0` The fault generation feature of the node cannot generate this type of error.

`0b1` The fault generation feature of the node allows generation of this type of error.

This bit reads-as-zero if the node does not support this type of error.

UEU, bit [2]

Unrecoverable Error generation. Describes whether the fault generation feature of the node can generate this type of error.

`0b0` The fault generation feature of the node cannot generate this type of error.

`0b1` The fault generation feature of the node allows generation of this type of error.

This bit reads-as-zero if the node does not support this type of error.

UC, bit [1]

Uncontainable Error generation. Describes whether the fault generation feature of the node can generate this type of error.

`0b0` The fault generation feature of the node cannot generate this type of error.

`0b1` The fault generation feature of the node allows generation of this type of error.

This bit reads-as-zero if the node does not support this type of error.

OF, bit [0]

Overflow flag. Describes how the fault generation feature of the node sets the ERR<n>STATUS.OF status flag.

`0b0` When an injected error is recorded, the node sets ERR<n>STATUS.OF according to the architecture-defined rules for setting the OF bit.

`0b1` When an injected error is recorded, ERR<n>STATUS.OF is set to ERR<n>PFGCTL.OF. This behavior replaces the architecture-defined rules for setting the OF bit.

This bit reads-as-zero if the node does not support this flag.

Accessing the ERR<n>PFGF:

ERR<n>PFGF can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0x800` + 64n	ERR<n>PFGF

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.31 ERR<n>STATUS, Error Record Primary Status Register, n = 0 - 65534

The ERR<n>STATUS characteristics are:

Purpose

Contains status information for the error record, including:

- Whether any error has been detected (valid).
- Whether any detected error was not corrected, and returned to a master.
- Whether any detected error was not corrected and deferred.
- Whether an error record has been discarded because additional errors have been detected before the first error was handled by software (overflow).
- Whether any error has been reported.
- Whether the other error record registers contain valid information.
- Whether the error was recorded because poison data was detected or because a corrupt value was detected by an error detection code.
- A primary error code.
- An IMPLEMENTATION DEFINED extended error code.

Within this register:

- The {AV, V, MV} bits are valid bits that define whether the error record registers are valid.
- The {UE, OF, CE, DE, UET} bits encode the type of error or errors recorded.
- The {CI, ER, PN, IERR, SERR} fields are syndrome fields.

Configurations

Some or all RW fields of this register have defined reset values.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERR<n>STATUS are UNDEFINED.

The number of error records that are implemented is IMPLEMENTATION DEFINED.

If error record <n> is not implemented, ERR<n>STATUS is RES0.

ERR<n>FR describes the features implemented by the node that owns error record <n>. <q> is the index of the first error record owned by the same node as error record <n>. If the node owns a single record, then q = n.

For IMPLEMENTATION DEFINED fields in this register, writing zero must always be supported to return the error record to an initial state.

In particular, if any IMPLEMENTATION DEFINED syndrome fields might generate a Fault Handling or Error Recovery Interrupt request, writing zero is sufficient to deactivate the Interrupt request.

Fields that are read-only, non-zero and ignore writes are compliant with this requirement.

Note

Arm recommends that any IMPLEMENTATION DEFINED syndrome fields that can generate a Fault Handling, Error Recovery, Critical, or IMPLEMENTATION DEFINED, interrupt request are disabled at Cold reset and are enabled by software writing an IMPLEMENTATION DEFINED non-zero value to an IMPLEMENTATION DEFINED field in ERR<q>CTRL, where q is the index of the first error record owned by the same node as error record n. If the node owns a single record then q = n.

Attributes

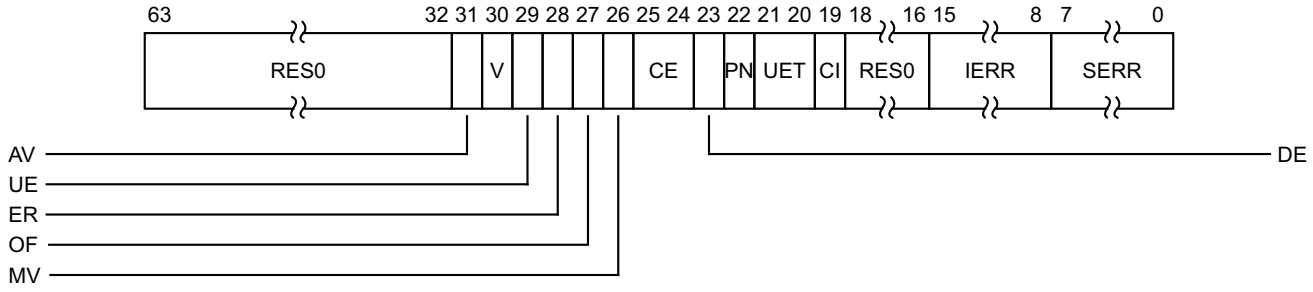
ERR<n>STATUS is a 64-bit register.

Field descriptions

The ERR<n>STATUS bit assignments are:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When ARMv8.4-RAS is implemented:



Bits [63:32]

Reserved, RES0.

AV, bit [31]

Address Valid.

`0b0` ERR<n>ADDR not valid.

`0b1` ERR<n>ADDR contains an address associated with the highest priority error recorded by this record.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to `0`.

V, bit [30]

Status Register Valid.

`0b0` ERR<n>STATUS not valid.

`0b1` ERR<n>STATUS valid. At least one error has been recorded.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to `0`.

UE, bit [29]

Uncorrected error.

`0b0` No errors have been detected, or all detected errors have been either corrected or deferred.

`0b1` At least one detected error was not corrected and not deferred.

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write one to this bit to clear this bit to zero.

This bit is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ER, bit [28]

Error Reported.

`0b0` No in-band error (External abort) reported.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` An External abort was signaled by the node to the master making the access or other transaction. This can be because any of the following are true:

- The applicable one of the ERR<n>CTLR.{WUE,RUE,UE} bits is implemented, and was set to 1 when an Uncorrected error was detected.
- The applicable one of the ERR<n>CTLR.{WUE,RUE,UE} bits is not implemented.

It is IMPLEMENTATION DEFINED whether this bit can be set to 1 by a Deferred error.

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write one to this bit to clear this bit to zero.

This bit is not valid and reads UNKNOWN if any of the following are true:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.UE is set to 0 and this bit is never set to 1 by a Deferred error.
- ERR<n>STATUS.{UE, DE} are both set to 0, and this bit can be set to 1 by a Deferred error.

This bit is read/write-one-to-clear.

Note

An External abort signaled by the node might be masked and not generate any exception.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

OF, bit [27]

Overflow.

Indicates that multiple errors have been detected. This bit is set to 1 when one of the following occurs:

- A Corrected error counter is implemented, an error is counted, and the counter overflows.
- ERR<n>STATUS.V was previously set to 1, a Corrected error counter is not implemented, and a Corrected error is recorded.
- ERR<n>STATUS.V was previously set to 1, and a type of error other than a Corrected error is recorded.

Otherwise, this bit is unchanged when an error is recorded.

If a Corrected error counter is implemented:

- A direct write that modifies the counter overflow flag indirectly might set this bit to an UNKNOWN value.
- A direct write to this bit that clears this bit to zero might indirectly set the counter overflow flag to an UNKNOWN value.

`0b0` Since this bit was last cleared to zero, no error syndrome has been discarded and, if a Corrected error counter is implemented, it has not overflowed.

`0b1` Since this bit was last cleared to zero, at least one error syndrome has been discarded or, if a Corrected error counter is implemented, it might have overflowed.

If this bit is nonzero, then software must write 1 to this bit, to clear this bit to zero, when clearing ERR<n>STATUS.V to 0.

This bit is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MV, bit [26]

Miscellaneous Registers Valid.

`0b0` ERR<n>MISC0, ERR<n>MISC1, ERR<n>MISC2, and ERR<n>MISC3 are not valid.

`0b1` The IMPLEMENTATION DEFINED contents of the ERR<n>MISC0, ERR<n>MISC1, ERR<n>MISC2, and ERR<n>MISC3 registers contain additional information for an error recorded by this record.

This bit is read/write-one-to-clear.

Note

If the ERR<n>MISC0, ERR<n>MISC1, ERR<n>MISC2, and ERR<n>MISC3 registers can contain additional information for a previously recorded error, then the contents must be self-describing to software or a user. For example, certain fields might relate only to Corrected errors, and other fields only to the most recent error that was not discarded.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to `0`.

CE, bits [25:24]

Corrected Error.

`0b00` No errors were corrected.

`0b01` At least one transient error was corrected.

`0b10` At least one error was corrected.

`0b11` At least one persistent error was corrected.

The mechanism by which a node detects whether a correctable error is transient or persistent is IMPLEMENTATION DEFINED. If no such mechanism is implemented, then the node sets this field to `0b10` when an error is corrected.

When clearing ERR<n>STATUS.V to 0, if this field is nonzero, then software must write ones to this field to clear this field to zero.

If ERR<n>STATUS.V is set to 0, this field is not valid and reads UNKNOWN.

This field is read/write-one-to-clear. Writing a value other than all-zeros or all-ones sets this field to an UNKNOWN value.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

DE, bit [23]

Deferred Error.

`0b0` No errors were deferred.

`0b1` At least one error was not corrected and deferred.

Support for deferring errors is IMPLEMENTATION DEFINED.

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write 1 to this bit to clear this bit to zero.

If ERR<n>STATUS.V is set to 0, this bit is not valid and reads UNKNOWN.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PN, bit [22]

Poison.

0b0 Uncorrected error or Deferred error recorded because a corrupt value was detected, for example, by an error detection code (EDC).

Note

If a producer node detects a corrupt value and defers the error by producing a poison value, then this bit is set to 0 at the producer node.

0b1 Uncorrected error or Deferred error recorded because a poison value was detected.

Note

This might only be an indication of poison, because, in some EDC schemes, a poison value is encoded as an unlikely form of corrupt data, meaning it is possible to mistake a corrupt value as a poison value.

It is IMPLEMENTATION DEFINED whether a node can distinguish a poison value from a corrupt value.

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write 1 to this bit to clear this bit to zero.

This bit is not valid and reads UNKNOWN if any of the following are true:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.{DE, UE} are both set to 0.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

UET, bits [21:20]

Uncorrected Error Type.

Describes the state of the component after detecting or consuming an Uncorrected error.

0b00 Uncorrected error, Uncontainable error (UC).

0b01 Uncorrected error, Unrecoverable error (UEU).

0b10 Uncorrected error, Latent or Restartable error (UEO).

0b11 Uncorrected error, Signaled or Recoverable error (UER).

When clearing ERR<n>STATUS.V to 0, if this field is nonzero, then software must write ones to this field to clear this field to zero.

This field is not valid and reads UNKNOWN if any of the following are true:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.UE is set to 0.

This field is read/write-one-to-clear. Writing a value other than all-zeros or all-ones sets this field to an UNKNOWN value.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

CI, bit [19]

Critical error.

Indicates whether a critical error condition has been recorded.

0b0 No critical error condition recorded.

0b1 Critical error condition recorded.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write 1 to this bit to clear this bit to zero.

This bit is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [18:16]

Reserved, RES0.

IERR, bits [15:8]

IMPLEMENTATION DEFINED error code.

Used with any primary error code SERR value. Further IMPLEMENTATION DEFINED information can be placed in the MISC registers.

This field is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SERR, bits [7:0]

Architecturally-defined primary error code.

Indicates the type of error. The primary error code might be used by a fault handling agent to triage an error without requiring device-specific code. For example, to count and threshold corrected errors in software, or generate a short log entry.

0x00	No error.
0x01	IMPLEMENTATION DEFINED error.
0x02	Data value from (non-associative) internal memory. For example, ECC from on-chip SRAM or buffer.
0x03	IMPLEMENTATION DEFINED pin. For example, nSEI pin.
0x04	Assertion failure. For example, consistency failure.
0x05	Error detected on internal data path. For example, parity on ALU result.
0x06	Data value from associative memory. For example, ECC error on cache data.
0x07	Address/control value from associative memory. For example, ECC error on cache tag.
0x08	Data value from a TLB. For example, ECC error on TLB data.
0x09	Address/control value from a TLB. For example, ECC error on TLB tag.
0x0A	Data value from producer. For example, parity error on write data bus.
0x0B	Address/control value from producer. For example, parity error on address bus.
0x0C	Data value from (non-associative) external memory. For example, ECC error in SDRAM.
0x0D	Illegal address (software fault). For example, access to unpopulated memory.
0x0E	Illegal access (software fault). For example, byte write to word register.
0x0F	Illegal state (software fault). For example, device not ready.
0x10	Internal data register. For example, parity on a SIMD&FP register. For a PE, all general-purpose, stack pointer, and SIMD&FP registers are data registers.
0x11	Internal control register. For example, Parity on a System register. For a PE, all registers other than general-purpose, stack pointer, and SIMD&FP registers are control registers.
0x12	Error response from slave. For example, error response from cache write-back.
0x13	External timeout. For example, timeout on interaction with another node.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x14` Internal timeout. For example, timeout on interface within the node.

`0x15` Deferred error from slave not supported at master. For example, poisoned data received from a slave by a master that cannot defer the error further.

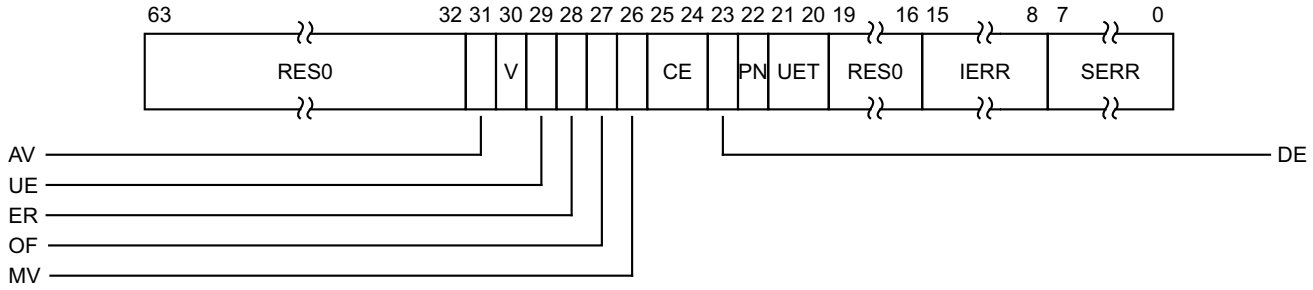
All other values are reserved. Reserved values might be defined in a future version of the architecture.

This field is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:



Bits [63:32]

Reserved, RES0.

AV, bit [31]

Address Valid.

`0b0` ERR<n>ADDR not valid.

`0b1` ERR<n>ADDR contains an address associated with the highest priority error recorded by this record.

This bit ignores writes if any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and the highest priority of these is not being cleared to 0 in the same write.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to `0`.

V, bit [30]

Status Register Valid.

`0b0` ERR<n>STATUS not valid.

`0b1` ERR<n>STATUS valid. At least one error has been recorded.

This bit ignores writes if any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and and is not being cleared to 0 in the same write.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to `0`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

UE, bit [29]

Uncorrected error.

`0b0` No errors have been detected, or all detected errors have been either corrected or deferred.

`0b1` At least one detected error was not corrected and not deferred.

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write one to this bit to clear this bit to zero.

If ERR<n>STATUS.OF is set to 1 and is not being cleared to 0 in the same write, this bit ignores writes.

This bit is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ER, bit [28]

Error Reported.

`0b0` No in-band error (External abort) reported.

`0b1` An External abort was signaled by the node to the master making the access or other transaction. This can be because any of the following are true:

- The applicable one of the ERR<n>CTLR.{WUE,RUE,UE} bits is implemented, and was set to 1 when an Uncorrected error was detected.
- The applicable one of the ERR<n>CTLR.{WUE,RUE,UE} bits is not implemented.

It is IMPLEMENTATION DEFINED whether this bit can be set to 1 by a Deferred error.

If this bit is nonzero, then software must write 1 to this bit, to clear this bit to zero, when:

- Clearing ERR<n>STATUS.V to 0.
- Clearing ERR<n>STATUS.UE to 0, if this bit is never set to 1 by a Deferred error.
- Clearing both ERR<n>STATUS.{UE, DE} to 0, if this bit can be set to 1 by a Deferred error.

This bit is not valid and reads UNKNOWN if any of the following are true:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.UE is set to 0 and this bit is never set to 1 by a Deferred error.
- ERR<n>STATUS.{UE, DE} are both set to 0, and this bit can be set to 1 by a Deferred error.

This bit ignores writes if any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and the highest priority of these is not being cleared to 0 in the same write.

This bit is read/write-one-to-clear.

Note

An External abort signaled by the node might be masked and not generate any exception.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

OF, bit [27]

Overflow.

Indicates that multiple errors have been detected. This bit is set to 1 when one of the following occurs:

- An Uncorrected error is detected and ERR<n>STATUS.UE == 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A Deferred error is detected, ERR<n>STATUS.UE == 0 and ERR<n>STATUS.DE == 1.
- A Corrected error is detected, no Corrected error counter is implemented, ERR<n>STATUS.UE == 0, ERR<n>STATUS.DE == 0, and ERR<n>STATUS.CE != `0b00`. ERR<n>STATUS.CE might be updated for the new Corrected error.
- A Corrected error counter is implemented, ERR<n>STATUS.UE == 0, ERR<n>STATUS.DE == 0, and the counter overflows.

It is IMPLEMENTATION DEFINED whether this bit is set to 1 when one of the following occurs:

- A Deferred error is detected and ERR<n>STATUS.UE == 1.
- A Corrected error is detected, no Corrected error counter is implemented, and either or both the ERR<n>STATUS.UE or ERR<n>STATUS.DE bits are set to 1.
- A Corrected error counter is implemented, either or both the ERR<n>STATUS.UE or ERR<n>STATUS.DE bits are set to 1, and the counter overflows.

It is IMPLEMENTATION DEFINED whether this bit is set to 0 when one of the following occurs:

- An Uncorrected error is detected and ERR<n>STATUS.UE == 0.
- A Deferred error is detected, ERR<n>STATUS.UE == 0 and ERR<n>STATUS.DE == 0.
- A Corrected error is detected, ERR<n>STATUS.UE == 0, ERR<n>STATUS.DE == 0 and ERR<n>STATUS.CE == `0b00`.

The IMPLEMENTATION DEFINED clearing of this bit might also depend on the value of the other error status bits.

If a Corrected error counter is implemented:

- A direct write that modifies the counter overflow flag indirectly might set this bit to an UNKNOWN value.
- A direct write to this bit that clears this bit to 0 might indirectly set the counter overflow flag to an UNKNOWN value.

`0b0` If ERR<n>STATUS.UE == 1, then no error syndrome for an Uncorrected error has been discarded.

If ERR<n>STATUS.UE == 0 and ERR<n>STATUS.DE == 1, then no error syndrome for a Deferred error has been discarded.

If ERR<n>STATUS.UE == 0, ERR<n>STATUS.DE == 0, and a Corrected error counter is implemented, then the counter has not overflowed.

If ERR<n>STATUS.UE == 0, ERR<n>STATUS.DE == 0, ERR<n>STATUS.CE != `0b00`, and no Corrected error counter is implemented, then no error syndrome for a Corrected error has been discarded.

Note

This bit might have been set to 1 when an error syndrome was discarded and later cleared to 0 when a higher priority syndrome was recorded.

`0b1` At least one error syndrome has been discarded or, if a Corrected error counter is implemented, it might have overflowed.

If this bit is nonzero, then software must write 1 to this bit, to clear this bit to zero, when clearing ERR<n>STATUS.V to 0.

This bit is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

MV, bit [26]

Miscellaneous Registers Valid.

`0b0` ERR<n>MISC0 and ERR<n>MISC1 not valid.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b1` The IMPLEMENTATION DEFINED contents of the ERR<n>MISC0 and ERR<n>MISC1 registers contains additional information for an error recorded by this record.

This bit ignores writes if any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and the highest priority of these is not being cleared to 0 in the same write.

This bit is read/write-one-to-clear.

Note

If the ERR<n>MISC0 and ERR<n>MISC1 registers can contain additional information for a previously recorded error, then the contents must be self-describing to software or a user. For example, certain fields might relate only to Corrected errors, and other fields only to the most recent error that was not discarded.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to `0`.

CE, bits [25:24]

Corrected Error.

`0b00` No errors were corrected.

`0b01` At least one transient error was corrected.

`0b10` At least one error was corrected.

`0b11` At least one persistent error was corrected.

The mechanism by which a node detects whether a correctable error is transient or persistent is IMPLEMENTATION DEFINED. If no such mechanism is implemented, then the node sets this field to `0b10` when an error is corrected.

When clearing ERR<n>STATUS.V to 0, if this field is nonzero, then software must write ones to this field to clear this field to zero.

If ERR<n>STATUS.OF is set to 1 and is not being cleared to 0 in the same write, this field ignores writes.

If ERR<n>STATUS.V is set to 0, this field is not valid and reads UNKNOWN.

This field is read/write-ones-to-clear. Writing a value other than all-zeros or all-ones sets this field to an UNKNOWN value.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

DE, bit [23]

Deferred Error.

`0b0` No errors were deferred.

`0b1` At least one error was not corrected and deferred.

Support for deferring errors is IMPLEMENTATION DEFINED.

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write 1 to this bit to clear this bit to zero.

If ERR<n>STATUS.OF is set to 1 and is not being cleared to 0 in the same write, this bit ignores writes.

If ERR<n>STATUS.V is set to 0, this bit is not valid and reads UNKNOWN.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PN, bit [22]

Poison.

0b0 Uncorrected error or Deferred error recorded because a corrupt value was detected, for example, by an error detection code (EDC).

Note

If a producer node detects a corrupt value and defers the error by producing a poison value, then this bit is set to 0 at the producer node.

0b1 Uncorrected error or Deferred error recorded because a poison value was detected.

Note

This might only be an indication of poison, because, in some EDC schemes, a poison value is encoded as an unlikely form of corrupt data, meaning it is possible to mistake a corrupt value as a poison value.

It is IMPLEMENTATION DEFINED whether a node can distinguish a poison value from a corrupt value.

When clearing ERR<n>STATUS.V to 0, if this bit is nonzero, then software must write 1 to this bit to clear this bit to zero.

When clearing both ERR<n>STATUS.{DE, UE} to 0, if this bit is nonzero, then software must write 1 to this bit to clear this bit to zero.

This bit is not valid and reads UNKNOWN if any of the following are true:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.{DE, UE} are both set to 0.

When any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and the highest priority of these is not being cleared to 0 in the same write, this bit ignores writes.

This bit is read/write-one-to-clear.

The following resets apply:

- This bit is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

UET, bits [21:20]

Uncorrected Error Type.

Describes the state of the component after detecting or consuming an Uncorrected error.

0b00 Uncorrected error, Uncontainable error (UC).

0b01 Uncorrected error, Unrecoverable error (UEU).

0b10 Uncorrected error, Latent or Restartable error (UEO).

0b11 Uncorrected error, Signaled or Recoverable error (UER).

When clearing ERR<n>STATUS.V to 0, if this field is nonzero, then software must write ones to this field to clear this field to zero.

When clearing ERR<n>STATUS.UE to 0, if this field is nonzero, then software must write ones to this field to clear this field to zero.

This field is not valid and reads UNKNOWN if any of the following are true:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.UE is set to 0.

When any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and the highest priority of these is not being cleared to 0 in the same write, this field ignores writes.

This field is read/write-ones-to-clear. Writing a value other than all-zeros or all-ones sets this field to an UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [19:16]

Reserved, RES0.

IERR, bits [15:8]

IMPLEMENTATION DEFINED error code.

Used with any primary error code SERR value. Further IMPLEMENTATION DEFINED information can be placed in the MISC registers.

This field is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

When any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and the highest priority of these is not being cleared to 0 in the same write, this field ignores writes.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SERR, bits [7:0]

Architecturally-defined primary error code.

Indicates the type of error. The primary error code might be used by a fault handling agent to triage an error without requiring device-specific code. For example, to count and threshold corrected errors in software, or generate a short log entry.

`0x00` No error.

`0x01` IMPLEMENTATION DEFINED error.

`0x02` Data value from (non-associative) internal memory. For example, ECC from on-chip SRAM or buffer.

`0x03` IMPLEMENTATION DEFINED pin. For example, nSEI pin.

`0x04` Assertion failure. For example, consistency failure.

`0x05` Error detected on internal data path. For example, parity on ALU result.

`0x06` Data value from associative memory. For example, ECC error on cache data.

`0x07` Address/control value from associative memory. For example, ECC error on cache tag.

`0x08` Data value from a TLB. For example, ECC error on TLB data.

`0x09` Address/control value from a TLB. For example, ECC error on TLB tag.

`0x0A` Data value from producer. For example, parity error on write data bus.

`0x0B` Address/control value from producer. For example, parity error on address bus.

`0x0C` Data value from (non-associative) external memory. For example, ECC error in SDRAM.

`0x0D` Illegal address (software fault). For example, access to unpopulated memory.

`0x0E` Illegal access (software fault). For example, byte write to word register.

`0x0F` Illegal state (software fault). For example, device not ready.

`0x10` Internal data register. For example, parity on a SIMD&FP register. For a PE, all general-purpose, stack pointer, and SIMD&FP registers are data registers.

`0x11` Internal control register. For example, Parity on a System register. For a PE, all registers other than general-purpose, stack pointer, and SIMD&FP registers are control registers.

`0x12` Error response from slave. For example, error response from cache write-back.

`0x13` External timeout. For example, timeout on interaction with another node.

`0x14` Internal timeout. For example, timeout on interface within the node.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x15` Deferred error from slave not supported at master. For example, poisoned data received from a slave by a master that cannot defer the error further.

All other values are reserved. Reserved values might be defined in a future version of the architecture.

This field is not valid and reads UNKNOWN if ERR<n>STATUS.V is set to 0.

When any of ERR<n>STATUS.{CE, DE, UE} are set to 1, and the highest priority of these is not being cleared to 0 in the same write, this field ignores writes.

The following resets apply:

- This field is preserved on an Error Recovery reset.
- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing the ERR<n>STATUS:

After reading the status register, software must clear the valid bits to allow new errors to be recorded.

Between reading the register and clearing the valid bits, a new error might have overwritten the register. To prevent this new error being lost:

- When ARMv8.4-RAS is not implemented, some control bits use a form of read/write-one-to-clear and ignore writes depending on the values of other bits and which bits are being cleared.
- When ARMv8.4-RAS is implemented, a write to ERR<n>STATUS is ignored if both:
  - Any of the ERR<n>STATUS.{V, UE, OF, CE, DE} fields are nonzero before the write.
  - The write does not clear the nonzero ERR<n>STATUS.{V, UE, OF, CE, DE} field(s) to zero by writing one(s) to the applicable field(s).

Software must write ones to the {ER, PN, UET, CI} fields when clearing ERR<n>STATUS.{V, UE, OF, CE, DE}.

ERR<n>STATUS can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0x010` + 64n	ERR<n>STATUS

This interface is accessible as follows:

- Accesses to this register are RW.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

I5.8.32 ERRPIDR0, Peripheral Identification Register 0

The ERRPIDR0 characteristics are:

Purpose

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

Implementation of this register is OPTIONAL.

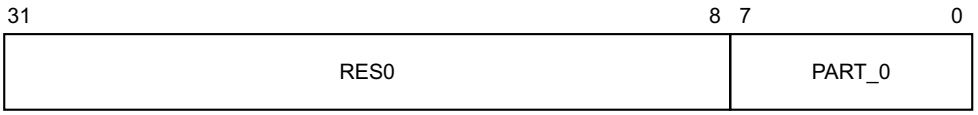
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRPIDR0 are RES0.

Attributes

ERRPIDR0 is a 32-bit register.

Field descriptions

The ERRPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, bits [7:0].

The part number is selected by the designer of the component. The designer chooses whether to use a 12-bit or a 16-bit part number, and:

- If a 12-bit part number is used, it is stored in ERRPIDR1.PART_1 and this field.
- If a 16-bit part number is used, it is stored in ERRPIDR2.PART_2, ERRPIDR1.PART_1 and this field.

This field reads as an IMPLEMENTATION DEFINED value.

Accessing the ERRPIDR0:

ERRPIDR0 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xFE0	ERRPIDR0

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.33 ERRPIDR1, Peripheral Identification Register 1

The ERRPIDR1 characteristics are:

Purpose

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

Implementation of this register is OPTIONAL.

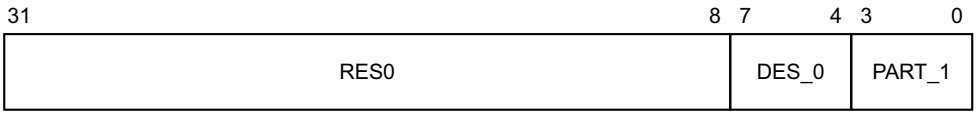
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRPIDR1 are RES0.

Attributes

ERRPIDR1 is a 32-bit register.

Field descriptions

The ERRPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, JEP106 identification code, bits [3:0]. This field and ERRPIDR2.DES_1 together form the JEDEC-assigned JEP106 identification code for the designer of the component.

The code identifies the designer of the component, which might not be not the same as the implementer of the device containing the component.

Note

For a component designed by Arm Limited, the JEP106 identification code is `0x3B`.

This field reads as an IMPLEMENTATION DEFINED value.

PART_1, bits [3:0]

Part number, bits [11:8]

The part number is selected by the designer of the component. The designer chooses whether to use a 12-bit or a 16-bit part number, and:

- If a 12-bit part number is used, it is stored in this field and ERRPIDR0.PART_0.
- If a 16-bit part number is used, it is stored in ERRPIDR2.PART_2, this field, and ERRPIDR0.PART_0.

This field reads as an IMPLEMENTATION DEFINED value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing the ERRPIDR1:

ERRPIDR1 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xFE4	ERRPIDR1

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.34 ERRPIDR2, Peripheral Identification Register 2

The ERRPIDR2 characteristics are:

Purpose

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

Implementation of this register is OPTIONAL.

This register is present only when RAS is implemented. Otherwise, direct accesses to ERRPIDR2 are RES0.

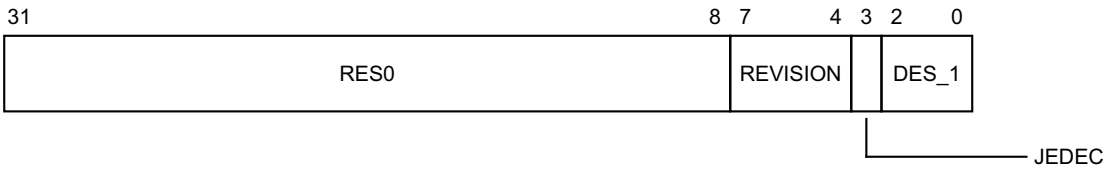
Attributes

ERRPIDR2 is a 32-bit register.

Field descriptions

The ERRPIDR2 bit assignments are:

When the component uses a 12-bit part number:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Component major revision. This field and ERRPIDR3.REVAND together form the revision number of the component, with REVISION being the most significant part and REVAND the least significant part.

This field reads as an IMPLEMENTATION DEFINED value.

JEDEC, bit [3]

JEDEC-assigned JEP106 implementer code is used. This bit is RAO.

DES_1, bits [2:0]

Designer, JEP106 identification code, bits [6:4]. ERRPIDR1.DES_0 and this field together form the JEDEC-assigned JEP106 identification code for the designer of the component.

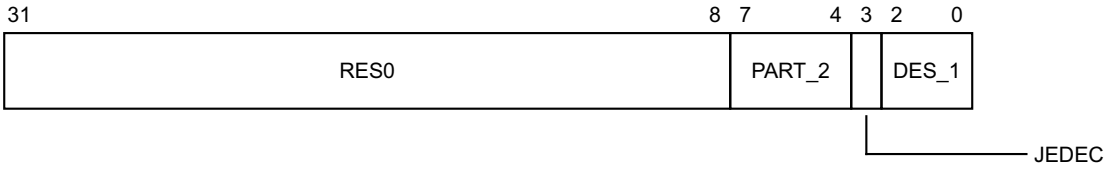
This field reads as an IMPLEMENTATION DEFINED value.

Note

For a component designed by Arm Limited, the JEP106 identification code is `0x3B`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the component uses a 16-bit part number:



Bits [31:8]

Reserved, RES0.

PART_2, bits [7:4]

Part number, bits [15:12]

The part number is selected by the designer of the component. It is stored in this field, ERRPIDR1.PART_1 and ERRPIDR0.PART_0.

This field reads as an IMPLEMENTATION DEFINED value.

JEDEC, bit [3]

JEDEC-assigned JEP106 implementer code is used. This bit is RAO.

DES_1, bits [2:0]

Designer, JEP106 identification code, bits [6:4]. ERRPIDR1.DES_0 and this field together form the JEDEC-assigned JEP106 identification code for the designer of the component.

This field reads as an IMPLEMENTATION DEFINED value.

Note

For a component designed by Arm Limited, the JEP106 identification code is `0x3B`.

Accessing the ERRPIDR2:

ERRPIDR2 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	`0xFE8`	ERRPIDR2

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.35 ERRPIDR3, Peripheral Identification Register 3

The ERRPIDR3 characteristics are:

Purpose

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

Implementation of this register is OPTIONAL.

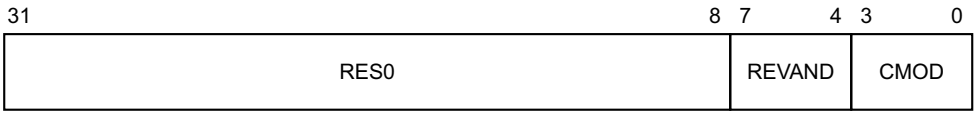
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRPIDR3 are RES0.

Attributes

ERRPIDR3 is a 32-bit register.

Field descriptions

The ERRPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

When the component uses a 12-bit part number:

Component minor revision. ERRPIDR2.REVISION and this field together form the revision number of the component, with REVISION being the most significant part and REVAND the least significant part.

This field reads as an IMPLEMENTATION DEFINED value.

When the component uses a 16-bit part number:

Component revision.

This field reads as an IMPLEMENTATION DEFINED value.

Otherwise:

Reserved, RES0.

CMOD, bits [3:0]

Customer Modified. If the value of this field is non-zero, then the component has IMPLEMENTATION DEFINED modifications.

`0b0000` The component is not modified from the original design.

For any two components with the same Unique Component Identifier:

- If the value of the CMOD fields of both components equals zero, the components are identical.
- If the value of the CMOD field of either of the two components is non-zero, they might not be identical, even though they have the same Unique Component Identifier.
- If the CMOD fields of both components have the same non-zero value, it does not necessarily mean that they have the same modifications.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field reads as an IMPLEMENTATION DEFINED value.

Accessing the ERRPIDR3:

ERRPIDR3 can be accessed through its memory-mapped interface:

Component	Offset	Instance
RAS	0xFEC	ERRPIDR3

This interface is accessible as follows:

- Accesses to this register are RO.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I5.8.36 ERRPIDR4, Peripheral Identification Register 4

The ERRPIDR4 characteristics are:

Purpose

Provides discovery information about the component.

For more information, see *About the Peripheral identification scheme* on page K2-7661 in the Arm® Architecture Reference Manual, Armv8, for Armv8-A architecture profile.

Configurations

Implementation of this register is OPTIONAL.

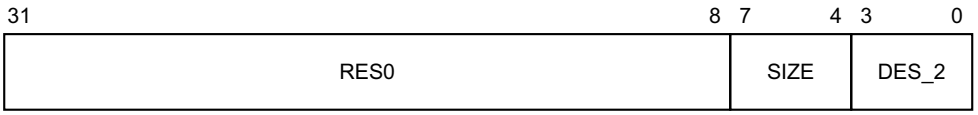
This register is present only when RAS is implemented. Otherwise, direct accesses to ERRPIDR4 are RES0.

Attributes

ERRPIDR4 is a 32-bit register.

Field descriptions

The ERRPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. The distance from the start of the address space used by this component to the end of the component identification registers.

If the value of this field is non-zero, then the component occupies $2^{ERRPIDR4.SIZE}$ 4KB blocks.

`0b0000` One of the following is true:

- The component uses a single 4KB block.
- The component uses an IMPLEMENTATION DEFINED number of 4KB blocks.

Using this bit field to indicate the size of the component is deprecated. This bit field might not correctly indicate the size of the component.

Arm recommends that software determine the size of the component from the Unique Component Identifier fields, and other IMPLEMENTATION DEFINED registers in the component.

This register reads as an IMPLEMENTATION DEFINED value.

DES_2, bits [3:0]

Designer, JEP106 continuation code. This is the JEDEC-assigned JEP106 bank identifier for the designer of the component, minus 1.

The code identifies the designer of the component, which might not be not the same as the implementer of the device containing the component.

This field reads as an IMPLEMENTATION DEFINED value.

Note

For a component designed by Arm Limited, the JEP106 bank is 5, meaning this field has the value `0x4`.

Part J

Architectural Pseudocode

Chapter J1
Armv8 Pseudocode

This chapter contains pseudocode that describes many features of the Armv8 architecture. It contains the following sections:

- *Pseudocode for AArch64 operations* on page J1-7300.
- *Pseudocode for AArch32 operation* on page J1-7415.
- *Shared pseudocode* on page J1-7493.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

J1.1 Pseudocode for AArch64 operations

This section holds the pseudocode for execution in AArch64 state. Functions that are listed in this section are identified as `AArch64.FunctionName`. Some of these functions have an equivalent AArch32 function, `AArch32.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch64/debug/breakpoint`.

The top-level sections of the AArch64 pseudocode hierarchy are:

- *aarch64/debug*.
- *aarch64/exceptions* on page J1-7311.
- *aarch64/functions* on page J1-7331.
- *aarch64/instrs* on page J1-7386.
- *aarch64/translation* on page J1-7394.

J1.1.1 aarch64/debug

This section includes the following pseudocode functions:

- *aarch64/debug/breakpoint/AArch64.BreakpointMatch*.
- *aarch64/debug/breakpoint/AArch64.BreakpointValueMatch* on page J1-7301.
- *aarch64/debug/breakpoint/AArch64.StateMatch* on page J1-7302.
- *aarch64/debug/breakpoint/CheckValidStateMatch* on page J1-7303.
- *aarch64/debug/enables/AArch64.GenerateDebugExceptions* on page J1-7304.
- *aarch64/debug/enables/AArch64.GenerateDebugExceptionsFrom* on page J1-7304.
- *aarch64/debug/pmu/AArch64.CheckForPMUOverflow* on page J1-7305.
- *aarch64/debug/pmu/AArch64.CountEvents* on page J1-7305.
- *aarch64/debug/statisticalprofiling/CheckProfilingBufferAccess* on page J1-7306.
- *aarch64/debug/statisticalprofiling/CheckStatisticalProfilingAccess* on page J1-7306.
- *aarch64/debug/statisticalprofiling/CollectContextIDR1* on page J1-7306.
- *aarch64/debug/statisticalprofiling/CollectContextIDR2* on page J1-7307.
- *aarch64/debug/statisticalprofiling/CollectPhysicalAddress* on page J1-7307.
- *aarch64/debug/statisticalprofiling/CollectRecord* on page J1-7307.
- *aarch64/debug/statisticalprofiling/CollectTimeStamp* on page J1-7308.
- *aarch64/debug/statisticalprofiling/OpType* on page J1-7308.
- *aarch64/debug/statisticalprofiling/ProfilingBufferEnabled* on page J1-7308.
- *aarch64/debug/statisticalprofiling/ProfilingBufferOwner* on page J1-7308.
- *aarch64/debug/statisticalprofiling/ProfilingSynchronizationBarrier* on page J1-7308.
- *aarch64/debug/statisticalprofiling/StatisticalProfilingEnabled* on page J1-7309.
- *aarch64/debug/statisticalprofiling/SysRegAccess* on page J1-7309.
- *aarch64/debug/statisticalprofiling/TimeStamp* on page J1-7309.
- *aarch64/debug/takeexceptiondbg/AArch64.TakeExceptionInDebugState* on page J1-7309.
- *aarch64/debug/watchpoint/AArch64.WatchpointByteMatch* on page J1-7310.
- *aarch64/debug/watchpoint/AArch64.WatchpointMatch* on page J1-7311.

aarch64/debug/breakpoint/AArch64.BreakpointMatch

```
// AArch64.BreakpointMatch()
// =========================
// Breakpoint matching in an AArch64 translation regime.

boolean AArch64.BreakpointMatch(integer n, bits(64) vaddress, AccType acctype, integer size)
    assert !ELUsingAArch32(S1TranslationRegime());
    assert n <= UInt(ID_AA64DFR0_EL1.BRPs);

    enabled = DBGBCR_EL1[n].E == '1';
    ispriv = PSTATE.EL != EL0;
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    linked = DBGBCR_EL1[n].BT == '0x01';
    isbreakpnt = TRUE;
    linked_to = FALSE;

    state_match = AArch64.StateMatch(DBGBCR_EL1[n].SSC, DBGBCR_EL1[n].HMC, DBGBCR_EL1[n].PMC,
                                     linked, DBGBCR_EL1[n].LBN, isbreakpnt, acctype, ispriv);
    value_match = AArch64.BreakpointValueMatch(n, vaddress, linked_to);

    if HaveAnyAArch32() && size == 4 then                 // Check second halfword
        // If the breakpoint address and BAS of an Address breakpoint match the address of the
        // second halfword of an instruction, but not the address of the first halfword, it is
        // CONSTRAINED UNPREDICTABLE whether or not this breakpoint generates a Breakpoint debug
        // event.
        match_i = AArch64.BreakpointValueMatch(n, vaddress + 2, linked_to);
        if !value_match && match_i then
            value_match = ConstrainUnpredictableBool();

    if vaddress<1> == '1' && DBGBCR_EL1[n].BAS == '1111' then
        // The above notwithstanding, if DBGBCR_EL1[n].BAS == '1111', then it is CONSTRAINED
        // UNPREDICTABLE whether or not a Breakpoint debug event is generated for an instruction
        // at the address DBGBVR_EL1[n]+2.
        if value_match then value_match = ConstrainUnpredictableBool();

    match = value_match && state_match && enabled;

    return match;
```

J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as `AArch32.FunctionName`. Some of these functions have an equivalent AArch64 function, `AArch64.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch32/debug/breakpoint`.

Note

Many AArch32 pseudocode functions have not been updated to show the constraints on the Armv7 UNPREDICTABLE behaviors that are described in Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*. Where AArch32 pseudocode shows something to be UNPREDICTABLE, check Appendix K1 for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- *aarch32/debug*.
- *aarch32/exceptions* on page J1-7424.
- *aarch32/functions* on page J1-7443.
- *aarch32/translation* on page J1-7471.

J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- *aarch32/debug/VCRMatch/AArch32.VCRMatch*.
- *aarch32/debug/authentication/AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled* on page J1-7416.
- *aarch32/debug/breakpoint/AArch32.BreakpointMatch* on page J1-7416.
- *aarch32/debug/breakpoint/AArch32.BreakpointValueMatch* on page J1-7417.
- *aarch32/debug/breakpoint/AArch32.StateMatch* on page J1-7418.
- *aarch32/debug/breakpoint/CheckValidStateMatch* on page J1-7419.
- *aarch32/debug/enables/AArch32.GenerateDebugExceptions* on page J1-7420.
- *aarch32/debug/enables/AArch32.GenerateDebugExceptionsFrom* on page J1-7420.
- *aarch32/debug/pmu/AArch32.CheckForPMUOverflow* on page J1-7420.
- *aarch32/debug/pmu/AArch32.CountEvents* on page J1-7421.
- *aarch32/debug/takeexceptiondbg/AArch32.EnterHypModeInDebugState* on page J1-7422.
- *aarch32/debug/takeexceptiondbg/AArch32.EnterModeInDebugState* on page J1-7422.
- *aarch32/debug/takeexceptiondbg/AArch32.EnterMonitorModeInDebugState* on page J1-7423.
- *aarch32/debug/watchpoint/AArch32.WatchpointByteMatch* on page J1-7423.
- *aarch32/debug/watchpoint/AArch32.WatchpointMatch* on page J1-7424.

J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a `FunctionName`, without an `AArch64.` or `AArch32.` prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`.

The top-level sections of the shared pseudocode hierarchy are:

- *shared/debug*.
- *shared/exceptions* on page J1-7512.

Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the Armv8 architecture. It contains the following sections:

- *AArch32 CONSTRAINED UNPREDICTABLE behaviors* on page K1-7606.
- *AArch64 CONSTRAINED UNPREDICTABLE behaviors* on page K1-7630.

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

Armv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in Armv7. The following sections define those constraints:

- *Overview of the constraints on Armv7 UNPREDICTABLE behaviors* on page K1-7607.
- *Using R13* on page K1-7607.
- *Using R15* on page K1-7607.
- *Branching into an IT block* on page K1-7608.
- *Branching to an unaligned PC* on page K1-7608.
- *Loads and Stores to unaligned locations* on page K1-7608.
- *CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT* on page K1-7608.
- *Unallocated System register access instructions* on page K1-7609.
- *SBZ or SBO fields T32 and A32 in instructions* on page K1-7610.
- *UNPREDICTABLE cases in immediate constants in T32 data-processing instructions* on page K1-7610.
- *UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions* on page K1-7611.
- *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-7611.
- *CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization* on page K1-7612
- *Translation Table Base Address alignment* on page K1-7612.
- *Handling of System register control fields for Advanced SIMD and floating-point operation* on page K1-7612.
- *The Performance Monitors Extension* on page K1-7613.
- *The Activity Monitors Extension* on page K1-7615.
- *Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED* on page K1-7615.
- *Out of range VA* on page K1-7616.
- *Instruction fetches from Device memory* on page K1-7616.
- *Multi-access instructions that load the PC from Device memory* on page K1-7616.
- *Programming CSSELR.Level for a cache level that is not implemented* on page K1-7616.
- *Crossing a page boundary with different memory types or Shareability attributes* on page K1-7617.
- *Crossing a 4KB boundary with a Device access* on page K1-7617.
- *UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs* on page K1-7617.
- *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings* on page K1-7618.
- *Out of range values of the Set/Way/Index fields in cache maintenance instructions* on page K1-7619.
- *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set* on page K1-7619.
- *CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions* on page K1-7621.

- *CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR* on page K1-7625.
- *CONSTRAINED UNPREDICTABLE behavior of EL2 features* on page K1-7625.
- *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7628.
- *CONSTRAINED UNPREDICTABLE behavior in Debug state* on page K1-7629.

K1.1.1 Overview of the constraints on Armv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the Armv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note

Software designed to be compatible with the Armv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

K1.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the Armv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

K1.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this Manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a `NOP`.
- Read or return an UNKNOWN value for the source register specified as R15.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a `NOP`.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example `LDRD`, `MRRC`, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of PSTATE.{N, Z, C, V}, PSTATE.Q, and PSTATE.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN,

In addition, for `MRC` instructions that use R15 as the destination register descriptor, and therefore target APSR_nzcv where these are described as being CONSTRAINED UNPREDICTABLE, PSTATE.{N, Z, C, V} becomes UNKNOWN.

K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its Condition code check within an IT block.
- Executed as a `NOP`. That is, it behaves as if it had failed the Condition code check.

K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates an exception on the first instruction using the unaligned PC value.

  If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:
  - EL2 is using AArch32 and the value of HCR.TGE is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.TGE is 1.

  If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1.

  If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.

  In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

If the exception that results from a branch to an unaligned PC value:

- Is taken to an Exception level that is using AArch64, it is reported as a PC alignment fault exception, see *ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault* on page D13-2935.
- Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see *Prefetch Abort exception reporting a PC alignment fault exception* on page G1-5544.

Note

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of IFAR, HIFAR, or FAR_ELx is 0 for all these cases.

K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the Armv7 architecture are described as UNPREDICTABLE. These are defined in the Armv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the Condition code check.
- The instructions execute as `NOP`s. This means that they behave as if they had failed the Condition code check.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the PSTATE.IT state machine must be treated in one of the following ways:

- PSTATE.IT is cleared to 0.
- PSTATE.IT advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

Note

This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC must do one of the following:

- Execute as if they had passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they had failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in *Branching into an IT block* on page K1-7608.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause PSTATE.IT to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in PSTATE.IT, the PSTATE.IT bits are forced to ‘00000000’. The reserved values are:

```
PSTATE.IT[7:4] != ‘0000’ && PSTATE.IT[3:0] = ‘0000’
PSTATE.IT[2:0] != ‘000’ when SCTLR/SCTLR_EL_1.ITD == ‘1’
```

Exception returns or Debug state exits that set PSTATE.IT to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the PSTATE.IT bits set to a value other than ‘00000000’.
- Inside an IT block, but with a different value of the PSTATE.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they failed the Condition code check for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in *Branching into an IT block* on page K1-7608.

The remaining iterations of the PSTATE.IT state machine must behave in one of the following ways:

- The PSTATE.IT state machine advances as if it were in an IT block.
- The PSTATE.IT bits are ignored.
- The PSTATE.IT bits are forced to ‘00000000’.

K1.1.8 Unallocated System register access instructions

In Armv8-A, accesses to unallocated System register encodings are UNDEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This includes:

- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- `MCR` or `MRC` accesses to using a set of {`coproc`, `CRn`, `opc1`, `CRm`, `opc2`} values that the Armv7 architecture defined as UNPREDICTABLE.
- Accesses to System registers in the (`coproc`==`0b111x`) encoding space that the Armv7 architecture defined as UNPREDICTABLE when particular functionality was not implemented, when an Armv8 implementation does not include the Exception level that provides that functionality.

K1.1.9 SBZ or SBO fields T32 and A32 in instructions

Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:

- *LDM, LDMIA, LDMFD* on page F5-4224.
- *LDMDB, LDMEA* on page F5-4234.
- *LDR (literal)* on page F5-4243.

- *PUSH* on page F5-4418.
- *SDIV* on page F5-4498.
- *STM, STMIA, STMEA* on page F5-4591.
- *STMDB, STMFD* on page F5-4599.
- *UDIV* on page F5-4713.

K1.1.10 UNPREDICTABLE cases in immediate constants in T32 data-processing instructions

The description of immediate constants in T32 data processing *Modified immediate constants in T32 instructions* on page F2-3923 include constant values that were UNPREDICTABLE in Armv7. *Instruction encodings* on page F2-3904 describes 32-bit T32 instructions as {`hw1`, `hw2`}, where `hw1` is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:

- `hw2`[7:0] == `0b0000000`.
- `hw1`[10] == `0` and either:
  - `hw2`[14:12] == `0b001`.
  - `hw2`[14:12] == `0b010`.
  - `hw2`[14:12] == `0b011`.

In Armv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value `0b0000000`.

K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F2-3925 include constant values that were UNPREDICTABLE in Armv7. The UNPREDICTABLE cases are those where:

- The bits that the encoding diagram shows as `abcd` are all 0.

  In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits {`hw1`[12, 2:0], `hw2`[3:0]}.

- The bits that the encoding diagram shows as `cmode[3:1]` are one of {`0b001`, `0b010`, `0b011`, `0b101`, `0b110`}.

  In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits `hw2`[11:9].

In Armv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The Arm architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

Note

If the *Effective value* of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that *Effective value* must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits within a TLB might generate an exception, reporting the exception using the TLB Conflict fault code, see *TLB conflict aborts* on page G5-5791.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K1.1.13 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The Arm architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.1.14 Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and TTBR0[13-N:7], which is defined to be RES0, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and TTBR0[x-1:3], TTBR1[x-1:3], HTTBR[x-1:3], or VTTBR[x-1:3], which are defined to be RES0, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

K1.1.15 Handling of System register control fields for Advanced SIMD and floating-point operation

For historical reasons described in *Background to the System register interface* on page G1-5568, each of the CPACR, HCPTR, and NSACR has a pair of control fields that were defined to have identical functionality for controlling Advanced SIMD and floating-point operation. These fields are:

- CPACR.{cp10, cp11}.
- HCPTR.{TCP10, TCP11}.
- NSACR.{cp10, cp11}.

The architecture requires that both fields in one of these pairs are programmed to the same value. If this is not done, then the CONSTRAINED UNPREDICTABLE behavior is that behavior is the same as if the cp11, or TCP11, control field was equal to the cp10, or TCP10, field in all respects other than the value read back by a direct read of the register. After a register write that writes different values to the two fields of a pair, a direct read of the register might return an UNKNOWN value for the cp11 or TCP11 field.

Note

This means that, when different values are written to the {cp10, cp11} fields in a single register, the architecture permits but does not require that a read of that register returns the value written to the cp11 field.

CONSTRAINED UNPREDICTABLE CPACR and NSACR settings

If CPACR.cp<n> contains the encoding `'10'`, then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

Note

In Armv7, CPACR had a D32DIS bit, and NSACR had an NSD32DIS bit. There is no CPACR.D32DIS or NSACR.NSD32DIS in Armv8-A, and the corresponding bits in the two registers are RES0.

K1.1.16 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch32 state:

- *CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR*.
- *CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n>* on page K1-7614.
- *CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN* on page K1-7614.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER or PMXEVCNTR

If PMSELR.SEL is greater than the number of counters accessible at this Exception level, accesses to PMXEVTYPER or PMXEVCNTR can cause CONSTRAINED UNPREDICTABLE behavior. This occurs when one of the following is true:

- If PMSELR.SEL is not equal to 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in EL2 or EL3.
- If ARMv8.4-SecEL2 is disabled or is not implemented, PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in Secure EL1 or Secure EL0.
- If PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to HDCR.HPMN, and the PE is executing in EL1 or EL0.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

- Accesses to PMXEVTYPER or PMXEVCNTR from that mode are UNDEFINED.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as RAZ/WI.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode execute as NOPs.
- Accesses to PMXEVTYPER or PMXEVCNTR from that mode behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to PMXEVTYPER or PMXEVCNTR behave as if PMSELR.SEL is 31.
- If EL2 is implemented and enabled in the current Security state, and PMSELR.SEL is less than the number of implemented counters but greater than the number of accessible counters at this Exception level, access to PMXEVTYPER or PMXEVCNTR from EL1 or permitted access from EL0 is trapped to EL2.

If PMSELR.SEL is equal to 31, then one of the following behaviors must occur:

- Accesses to PMXEVCNTR are UNDEFINED.
- Accesses to PMXEVCNTR behave as RAZ/WI.
- Accesses to PMXEVCNTR execute as NOPs.
- Accesses to PMXEVCNTR behave as if PMSELR.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If EL2 is implemented and enabled in the current Security state, for an access to PMXEVCNTR from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

Note

If EL2 is implemented and enabled in the current Security state, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters at EL0 or EL1. Otherwise, the number of accessible counters is the number of implemented counters.

Accesses from EL0 to PMXEVCNTR are permitted when:

- EL1 is using AArch32 and the values of PMUSERENR.{ER, EN} are both 1.
- EL1 is using AArch64 and the values of PMUSERENR_EL0.{ER, EN} are both 1.

Accesses from EL0 to PMXEVTYPER are permitted when:

- EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
- EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n> and PMEVTYPER<n>

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n> and PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.
- If EL2 is implemented and enabled in the current Security state, for an access to PMEVCNTR<n> or PMEVTYPER<n> from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

  Accesses from EL0 are permitted to PMEVCNTR<n> when:

  — EL1 is using AArch32 and the values of PMUSERENR.{ER, EN} are both 1.

  — EL1 is using AArch64 and the values of PMUSERENR_EL0.{ER, EN} are both 1.

  Accesses from EL0 are permitted to PMEVTYPER<n> when:

  — EL1 is using AArch32 and the value of PMUSERENR.EN is 1.

  — EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Note

If EL2 is implemented and enabled in the current Security state, at EL0 and EL1, HDCR.HPMN, or MDCR_EL2.HPMN, identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRAINED UNPREDICTABLE behavior caused by HDCR.HPMN

If HDCR.HPMN is set to 0 or to a value greater than PMCR.N, then the CONSTRAINED UNPREDICTABLE behavior is:

- The value returned by a direct read of HDCR.HPMN is UNKNOWN.
- Either:

  — An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if HDCR.HPMN is set to an UNKNOWN non-zero value less than PMCR.N.

  — All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

K1.1.17 The Activity Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Activity Monitors registers in AArch32 state:

- *CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR0<n> and AMEVTYPER0<n>*.
- *CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR1<n> and AMEVTYPER1<n>*.
- *CONSTRAINED UNPREDICTABLE accesses to AMCNTENCLR1 and AMCNTENSET1*.

CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR0<n> and AMEVTYPER0<n>

If <n> is greater than the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n> and AMEVTYPER0<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

Note

AMCGCR.CG0NC identifies the number of architected activity monitor event counters.

CONSTRAINED UNPREDICTABLE accesses to AMEVCNTR1<n> and AMEVTYPER1<n>

If <n> is greater than the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1<n> and AMEVTYPER1<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

Note

AMCGCR.CG1NC identifies the number of auxiliary activity monitor event counters.

CONSTRAINED UNPREDICTABLE accesses to AMCNTENCLR1 and AMCNTENSET1

If the number of auxiliary activity monitor event counters that are implemented is zero, reads and writes of AMCNTENCLR1 and AMCNTENSET1 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.

Note

The number of auxiliary activity monitor event counters that are implemented is zero exactly when AMCFGR.NCG == `0b0000`.

K1.1.18 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:

- If this exception is taken to an Exception level that is using AArch64 then ESR_ELx is UNKNOWN.
- If this exception is taken to EL2 and EL2 is using AArch32, then the HSR is unknown.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.1.19 Out of range VA

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes `0xFFFF FFFF` and `0x0000 0000`, then the bytes that wrap around and appear to be from `0x0000 0000` onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes `0xFFFF FFFF` and `0x0000 0000`, then the bytes that wrap around and appear to be from `0x0000 0000` onwards come from an UNKNOWN address.

K1.1.20 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.1.21 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. In the Armv8-A architecture in AArch32 state an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a permission fault.

K1.1.22 Programming CSSELR.Level for a cache level that is not implemented

If CSSELR.Level is programmed to a cache level that is not implemented, then a read of CSSELR returns an UNKNOWN value in CSSELR.Level.

If CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation must perform one of the following behaviors:

- The CCSIDR read is treated as a `NOP`.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

When ARMv8.3-CCIDX is implemented, CCSIDR2 is implemented. If CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR2 an implementation must perform one of the following behaviors:

- The CCSIDR2 read is treated as a `NOP`.
- The CCSIDR2 read is UNDEFINED.
- The CCSIDR2 read returns an UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K1.1.23 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an alignment fault caused by the memory type.

  For the Non-secure PL1&0 translation regime:

  — If the stage 1 translation causes the mismatch then the resulting exception is taken to PL1.

  — If the stage 2 translation causes the mismatch then the resulting exception is taken to PL2.

  — If both stages of translation cause the mismatch then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a `NOP`.

K1.1.24 Crossing a 4KB boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.

  For the Non-secure PL1&0 translation regime:

  — If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to PL1.

  — If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to PL2.

  — If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a `NOP`.

Note

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.

K1.1.25 UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-3859 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in Armv7. In summary, these cases are:

- The target virtual address of a `StoreExcl` instruction is different from the virtual address of the preceding `LoadExcl` instruction in the same thread of execution.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The transaction size of a `StoreExcl` instruction is different from the transaction size of the preceding `LoadExcl` instruction in the same thread of execution.
- The memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, either:
  - Because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction.
  - Because the `LoadExcl` instruction and the `StoreExcl` instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page E2-3859 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

Note

Additional CONSTRAINED UNPREDICTABLE cases can apply to Load-Exclusive and Store-Exclusive instructions, see *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set* on page K1-7619.

K1.1.26 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings

The A32 and T32 instruction sets include encodings that result in CONSTRAINED UNPREDICTABLE behavior when they are decoded.

CONSTRAINED UNPREDICTABLE behavior of CRC32 instruction encodings

In the A32 and T32 instruction sets, there are encodings of the CRC32 and CRC32C instructions that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in the following places in the A32 and T32 instruction sets:

- *Cyclic Redundancy Check* on page F4-4014 for the A32 instruction set, with `sz = 11`.
- *Data-processing (two source registers)* on page F3-3999 for the T32 instruction set, with `op1 = 10x` and `op2 = 11`.

The CONSTRAINED UNPREDICTABLE behavior for these encodings is described in *CRC32* on page F5-4165 and *CRC32C* on page F5-4168.

CONSTRAINED UNPREDICTABLE behavior of other A32 instruction encodings

In the A32 instruction set, there are encodings that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in:

- *Miscellaneous* on page F4-4048.
- *Memory hints and barriers* on page F4-4059.
- *Barriers* on page F4-4060.

The CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

- The instruction encoding is UNDEFINED.
- The instruction encoding executes as `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K1.1.27 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Note

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW.

K1.1.28 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 System instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 System instructions.

Note

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

SRS (T32)

For a description of this instruction and the encoding, see *SRS, SRSDA, SRSDB, SRSIA, SRSIB* on page F5-4555.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SRS (A32)

For a description of this instruction and the encoding, see *SRS, SRSDA, SRSDB, SRSIA, SRSIB* on page F5-4555.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - R13 of the current mode is used.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see the exception return form of *SUB, SUBS (immediate)* on page F5-4657.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

For encoding T5:

- If `hw2`[3:0] are `0b1110`, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction is treated as if `hw2`[3:0] are `0b1110`.
  - The program counter is set using the value in the register specified by `hw2`[3:0].

SUBS PC. LR and related instructions (A32)

For a description of this instruction and the encoding, see the exception return forms of *MOV, MOVS (register)* on page F5-4343 and *SUB, SUBS (immediate)* on page F5-4657.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction transfers an illegal mode encoding to PSTATE.M, then this invokes the illegal exception return.

Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K1.1.29 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in *Alphabetical list of Advanced SIMD and floating-point instructions* on page F6-4782.

Note

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see *VCVT (between floating-point and fixed-point, floating-point)* on page F6-4939.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (multiple single elements)

For a description of this instruction and the encoding, see *VLD1 (multiple single elements)* on page F6-5025.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see *VLD1 (single element to all lanes)* on page F6-5022.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see *VLD2 (multiple 2-element structures)* on page F6-5042.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to one lane)* on page F6-5033.

K1.1.30 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR:

- *Misprogramming VTCR.S*.
- *Misprogramming VTCR.{SL0, T0SZ}*.

Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. For the Armv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

Note

The CONSTRAINED UNPREDICTABLE behavior described in *Misprogramming VTCR.{SL0, T0SZ}* means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

Misprogramming VTCR.{SL0, T0SZ}

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

K1.1.31 CONSTRAINED UNPREDICTABLE behavior of EL2 features

The following sections describe CONSTRAINED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- *ERET in User mode or System mode*.
- *Accessing Hyp mode from outside Hyp mode*.
- *Modifying PSTATE.M when in Hyp mode* on page K1-7626
- *Use of Hyp mode in Secure state* on page K1-7626.
- *Execution of Load/Store unprivileged instructions in Hyp mode* on page K1-7626.
- *Exception return to Hyp mode* on page K1-7626.
- *Accessing registers that cannot be accessed using MSR/MRS instructions* on page K1-7626.
- *Memory type handling* on page K1-7627.
- *Hyp mode TLB maintenance instructions* on page K1-7627.
- *Hyp mode VA to PA address translation instructions* on page K1-7627.
- *Stage 1 default memory type* on page K1-7627.
- *Trapping of general exceptions to Hyp mode* on page K1-7627.
- *Prevention of rootkits using Hyp mode or Secure state* on page K1-7628.
- *HVC* on page K1-7628.
- *MSR (banked register) and MRS (banked register)* on page K1-7628.

ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in *SUBS PC, LR and related instructions (T32)* on page K1-7620.

Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the `MSR` or `CPS` instruction invokes the Armv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

`SRS` using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page K1-7619 and *SRS (A32)* on page K1-7619.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the Armv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page K1-7619 and *SRS (A32)* on page K1-7619.

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the Armv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page K1-7619 and *SRS (A32)* on page K1-7619.

Execution of Load/Store unprivileged instructions in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure PL1 mode invokes the Armv8 illegal exception return.

Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

```
MSR <Rm>_<mode>, <Rn>
MSR SPSR_<mode>, <Rn>
MSR ELR_hyp, <Rn>
MRS <Rn>, <Rm>_<mode>
MRS <Rn>, SPSR_<mode>
MRS <Rn>, ELR_hyp
```

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For MRS instructions, the destination general-purpose register becomes UNKNOWN.
- For MSR instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

Hyp mode TLB maintenance instructions

If a TLBIMVAH, TLBIMVALH, TLBIMVAHIS, TLBIMVALHIS, TLBIALLH, TLBIALLHIS, TLBIALLNSNH, TLBIALLNSNHIS, TLBIIPAS2, TLBIIPAS2L, TLBIIPAS2IS, or TLBIIPAS2LIS instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see *The scope of TLB maintenance instructions* on page G5-5802.

Hyp mode VA to PA address translation instructions

If an ATS1HR or ATS1HW instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction is executes as if it had been executed in Monitor mode.

For more information about these instructions see *Address translation instruction naming and operation summary* on page G5-5841.

Stage 1 default memory type

If HCR.DC == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

- SCTLR.M == 0, regardless of the actual value of SCTLR.M, other than for the value returned by an explicit read of SCTLR.M.
- HCR.VM == 1, regardless of the actual value of HCR.VM, other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when HCR.TGE == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when HCR.TGE == 1 by executing a `CPS` or `MSR` instruction generates an Illegal Execution state exception, by not changing the mode, and setting PSTATE.IL to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when HCR.TGE is set, by changing SCR.NS from 0 to 1, results in no change of SCR.NS.

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when HCR.TGE == 1:

- All exceptions that would be routed to EL1 are routed to EL2.
- Non-secure SCTLR.M is treated as being 0, regardless of its actual value, other than for an explicit read of of this bit.
- HCR.FMO, HCR.IMO, and HCR.AMO are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.

Prevention of rootkits using Hyp mode or Secure state

If an HVC instruction is executed in Hyp mode when SCR.HCE == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

If an SMC instruction is executed in a Secure privileged mode when SCR.SCD == 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

HVC

For a description of this instruction and the encoding, see *HVC* on page F5-4201.

For the A1 encoding, if `cond field !=1110`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

MSR (banked register) and MRS (banked register)

Encoding and use of banked register transfer instructions on page F5-4777 identifies cases where attempted execution of an `MRS` (banked register) or `MSR` (banked register) was UNPREDICTABLE in Armv7 and becomes CONSTRAINED UNPREDICTABLE in Armv8. This includes cases where:

- The target register specified by the {`R`, `SYSm`} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed, see *Usage restrictions on the banked register transfer instructions* on page F5-4778.
- The instruction was executed specifying unallocated {`R`, `SYSm`} field values, see *Encoding the register argument in the banked register transfer instructions* on page F5-4779.

If one of these encodings for an `MSR` (banked register) or `MRS` (banked register) instruction is executed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- An allocated `MSR` (banked register) or `MRS` (banked register) instruction is executed.

K1.1.32 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

These constraints are identical to those for the equivalent AArch64 definitions, as given in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.

K1.1.33 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-6714 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- *Overview of the constraints on AArch64 UNPREDICTABLE behaviors*.
- *SBZ or SBO fields in A64 instructions*.
- *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values*.
- *CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization* on page K1-7631.
- *Translation table base address alignment* on page K1-7632.
- *The Performance Monitors Extension* on page K1-7632.
- *The Activity Monitors Extension* on page K1-7634.
- *Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED* on page K1-7634.
- *Out of range virtual address* on page K1-7635.
- *Instruction fetches from Device memory* on page K1-7635.
- *Programming the CSSELR_EL1.Level for a cache level that is not implemented* on page K1-7635.
- *Crossing a page boundary with different memory types or Shareability attributes* on page K1-7636.
- *Crossing a peripheral boundary with a Device access* on page K1-7636.
- *CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs* on page K1-7636.
- *CONSTRAINED UNPREDICTABLE behavior for A64 instructions* on page K1-7637.
- *Out of range values of the Set/Way/Index fields in cache maintenance instructions* on page K1-7644.
- *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7644.
- *CONSTRAINED UNPREDICTABLE behavior in Debug state* on page K1-7645.

K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the Armv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note

Software designed to be compatible with the Armv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

K1.2.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO, as described in *Fixed values in AArch64 instruction and System register descriptions* on page C2-185. Except for specific cases identified in *CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs* on page K1-7636, if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

K1.2.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The Arm architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

Note

If the *Effective value* of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that *Effective value* must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see *TLB conflict aborts* on page D5-2637.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

K1.2.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The Arm architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.2.5 Translation table base address alignment

In the translation table base registers TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, VTTBR_EL2, and TTBR0_EL3, register bits[48:*x*] hold the translation table base address, where *x* depends on the translation table granule size and the size of the addressed translation table, as described in *Memory translation granule size* on page D5-2526. Register bits[(*x*-1):0], unless redefined for another purpose, correspond to bits[(*x*-1):0] of the translation table base address and therefore are RES0.

Note

- When ARMv8.2-LPA is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.
- When ARMv8.2-TTCNP is implemented register bit[0] is redefined as the CnP bit.

For these registers, if one or more RES0 bits in register bits [(x-1):0] does not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
  - The value read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate TTBR.BADDR field description.

K1.2.6 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch64 state:

- *CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER_EL0 or PMXEVETYPER_EL0*.
- *CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0* on page K1-7633.
- *CONSTRAINED UNPREDICTABLE behavior caused by MDCR_EL2.HPMN* on page K1-7634.

CONSTRAINED UNPREDICTABLE accesses to PMXEVTYPER_EL0 or PMXEVETYPER_EL0

If PMSELR_EL0.SEL is greater than the number of counters accessible at this Exception level, accesses to PMXEVTYPER_EL0 and PMXEVCNTR_EL0 can cause CONSTRAINED UNPREDICTABLE behavior. This occurs when one of the following is true:

- If PMSELR_EL0.SEL is not equal to 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in EL2 or EL3.
- If ARMv8.4-SecEL2 is disabled or is not implemented, PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in Secure EL1 or Secure EL0.
- If PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to MDCR_EL2.HPMN, and the PE is executing in EL0 or EL1.

In these cases, one of the following behaviors must occur:

- Accesses to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state are UNDEFINED.
- Accesses to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state behave as RAZ/WI.
- Accesses to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state execute as `NOPs`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Accesses to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state behave as if PMSELR_EL0.SEL is 31.
- If EL2 is implemented and enabled in the current Security state, and PMSELR_EL0.SEL is less than the number of implemented counters but greater than or equal to the number of accessible counters at this Exception level, access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from EL1 or a permitted access from EL0 is trapped to EL2.

  Note

  If EL2 is implemented and enabled in the current Security state, MDCR_EL2.HPMN identifies the number of accessible counters at EL0 or EL1. Otherwise, the number of accessible counters is the number of implemented counters.

  Accesses from EL0 to PMXEVCNTR_EL0 are permitted when:

  — EL1 is using AArch32 and the values of PMUSERENR.{ER, EN} are both 1.
  — EL1 is using AArch64 and the values of PMUSERENR_EL0.{ER, EN} are both 1.

  Accesses from EL0 to PMXEVTYPER_EL0 are permitted when:

  — EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  — EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

If PMSELR_EL0.SEL is equal to 31, then one of the following behaviors must occur:

- Accesses to PMXEVCNTR_EL0 are UNDEFINED.
- Accesses to PMXEVCNTR_EL0 behave as RAZ/WI.
- Accesses to PMXEVCNTR_EL0 execute as `NOP`s.
- Accesses to PMXEVCNTR_EL0 behave as if PMSELR_EL0.SEL contains an unknown value that is less than the number of counters accessible at the current Exception level and Security state.

CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n>_EL0 and PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a `NOP`.
- If EL2 is implemented and enabled in the current Security state, for an access to PMEVCNTR<n>_EL0 or PMEVTYPER<n>_EL0 from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.

  Accesses from EL0 to PMEVCNTR<n>_EL0 are permitted when:

  — EL1 is using AArch32 and the value of PMUSERENR.{ER, EN} are both 1.
  — EL1 is using AArch64 and the value of PMUSERENR_EL0.{ER, EN} are both 1.

  Accesses from EL0 to PMEVTYPER<n>_EL0 are permitted when:

  — EL1 is using AArch32 and the value of PMUSERENR.EN is 1.
  — EL1 is using AArch64 and the value of PMUSERENR_EL0.EN is 1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CONSTRAINED UNPREDICTABLE behavior caused by MDCR_EL2.HPMN

If MDCR_EL2.HPMN is set to 0, or to a value larger than PMCR_EL0.N, then the following CONSTRAINED UNPREDICTABLE behavior applies:

- The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
- Either:
  - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN non-zero value less than PMCR_EL0.N.
  - All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

K1.2.7 The Activity Monitors Extension

If <n> is greater than the number of architected activity monitor event counters, reads and writes of AMEVCNTR0<n>_EL0 and AMEVTYPER0<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

Note

AMCGCR_EL0.CG0NC identifies the number of architected activity monitor event counters.

If <n> is greater than the number of auxiliary activity monitor event counters, reads and writes of AMEVCNTR1<n>_EL0and AMEVTYPER1<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

Note

AMCGCR_EL0.CG1NC identifies the number of auxiliary activity monitor event counters.

If the number of auxiliary activity monitor event counters that are implemented is zero, reads and writes of AMCNTENCLR1_EL0 and AMCNTENSET0_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

Note

The number of auxiliary activity monitor event counters that are implemented is zero exactly when AMCFGR_EL0.NCG == 0b0000.

K1.2.8 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, ESR_ELx is UNKNOWN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The value written to ESR_ELx must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.2.9 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an unknown address and the tags associated with address also become unknown.

Note

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address `0xFFFF FFFF FFFF FFFF` and the byte at virtual address `0x0000 0000 0000 0000`.

K1.2.10 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.2.11 Programming the CSSELR_EL1.Level for a cache level that is not implemented

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 returns an UNKNOWN value in CSSELR_EL1.Level.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR_EL1 read is treated as a `NOP`.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

When ARMv8.3-CCIDX is implemented, CCSIDR2_EL1 is implemented. If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR2_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR2_EL1 read is treated as a `NOP`.
- The CCSIDR2_EL1 read is UNDEFINED.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K1.2.12 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.

  For the EL1&0 translation regime, when EL2 is enabled in the current Security state:
  - If the stage 1 translation generated the mismatch then the resulting exception is taken to EL1.
  - If the stage 2 translation generated the mismatch then the resulting exception is taken to EL2.
  - If both stages of translation generate the mismatch then the exception can be taken to either EL1 or EL2.
- The instruction executes as a `NOP`.

K1.2.13 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The instruction generates an alignment fault caused by the memory type.

  For the EL1&0 translation regime, when EL2 is enabled in the current Security state:
  - If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to EL1.
  - If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to EL2.
  - If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either EL1 or EL2.
- The instruction executes as a `NOP`.

Note

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

K1.2.14 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-163 defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a `StoreExcl` instruction is different from the virtual address of the preceding `LoadExcl` instruction in the same thread of execution.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The transaction size of a `StoreExcl` instruction is different from the transaction size of the preceding `LoadExcl` instruction in the same thread of execution.
- The `StoreExcl` instruction accesses a different number of registers than the preceding `LoadExcl` instruction in the same thread of execution.
- The memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, either:
  - Because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction.
  - Because the `LoadExcl` instruction and the `StoreExcl` instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page B2-163 for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

K1.2.15 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in Chapter C6 *A64 Base Instruction Descriptions* and Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.

LDAXP

For a description of this instruction and the encoding, see *LDAXP* on page C6-942.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

LDNP

For a description of this instruction and the encoding, see *LDNP* on page C6-968.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

LDNP (SIMD&FP)

For a description of this instruction and the encoding, see *LDNP (SIMD&FP)* on page C7-1794.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

LDP

For a description of this instruction and the encoding, see *LDP* on page C6-970.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs all of the loads using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDP (SIMD&FP)

For a description of this instruction and the encoding, see *LDP (SIMD&FP)* on page C7-1796.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

LDPSW

For a description of this instruction and the encoding, see *LDPSW* on page C6-973.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDR (immediate)

For a description of this instruction and the encoding, see *LDR (immediate)* on page C6-976.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRB (immediate)

For a description of this instruction and the encoding, see *LDRB (immediate)* on page C6-985.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRH (immediate)

For a description of this instruction and the encoding, see *LDRH (immediate)* on page C6-990.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LDRSB (immediate)

For a description of this instruction and the encoding, see *LDRSB (immediate)* on page C6-995.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSH (immediate)

For a description of this instruction and the encoding, see *LDRSH (immediate)* on page C6-1000.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSW (immediate)

For a description of this instruction and the encoding, see *LDRSW (immediate)* on page C6-1005.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDXP

For a description of this instruction and the encoding, see *LDXP* on page C6-1067.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

STP

For a description of this instruction and the encoding, see *STP* on page C6-1236.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STLXP

For a description of this instruction and the encoding, see *STLXP* on page C6-1225.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (s == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXR

For a description of this instruction and the encoding, see *STLXR* on page C6-1228.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

STLXRB

For a description of this instruction and the encoding, see *STLXRB* on page C6-1230.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXRH

For a description of this instruction and the encoding, see *STLXRH* on page C6-1232.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STR (immediate)

For a description of this instruction and the encoding, see *STR (immediate)* on page C6-1239.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STRB (immediate)

For a description of this instruction and the encoding, see *STRB (immediate)* on page C6-1244.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STRH (immediate)

For a description of this instruction and the encoding, see *STRH (immediate)* on page C6-1249.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

STXP

For a description of this instruction and the encoding, see *STXP* on page C6-1294.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (s == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXR

For a description of this instruction and the encoding, see *STXR* on page C6-1297.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXRB

For a description of this instruction and the encoding, see *STXRB* on page C6-1299.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXRH

For a description of this instruction and the encoding, see *STXRH* on page C6-1301.

CONSTRAINED UNPREDICTABLE behavior

If `s == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If `s == n && n != 31` then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

K1.2.16 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions DC CISW, DC CSW, and DC ISW, if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Note

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the AArch32 cache maintenance by set/way instructions DCCISW, DCCSW, and DCISW.

K1.2.17 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

These constraints are identical to those for the equivalent AArch32 definitions, as given in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-7628.

K1.2.18 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-6714 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

Appendix K2
Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

- *About the recommended external debug interface* on page K2-7648.
- *PMUEVENT bus* on page K2-7652.
- *Recommended authentication interface* on page K2-7653.
- *Management registers and CoreSight compliance* on page K2-7655.

Note

This recommended external debug interface specification is not part of the Arm architecture specification. Implementers and users of the Armv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of Arm products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any Arm products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K2.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for Armv8 to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection. Table K2-1 shows the signals in the recommended interface.

Table K2-1 Recommended debug interface signals

Name	Direction	Description	Notes
DBGEN	In	External debug enable	-
SPIDEN	In	Secure privileged external debug enable	-
		Secure privileged self-hosted debug enable	Only in Secure AArch32 modes when enabled by MDCR_EL3.SPD32
NIDEN	In	External profiling and trace enable	If ARMv8.4-Debug is implemented, this signal is not implemented.
SPNIDEN	In	Secure external profiling and trace enable	If ARMv8.4-Debug is implemented, this signal is not implemented.
EDBGRQ	In	External halt request	IMPLEMENTATION DEFINED mechanism to halt the PE. See *EDBGRQ and DBGACK* on page K2-7651.
DBGACK	Out	Debug Acknowledge	Indicate to the system that a PE is in Debug state. See *EDBGRQ and DBGACK* on page K2-7651.
COMMIRQ	Out	DCC interrupt	Interface to an interrupt controller. See *Interrupt-driven use of the DCC* on page H4-6786 and the pseudocode for function `CheckForDCCInterrupts()`.
PMUIRQ	Out	Performance Monitor overflow	Interface to an interrupt controller. See *Behavior on overflow* on page D7-2675.
COMMRX	Out	DTRRX is full	Provided for legacy connection to an interrupt controller only. See *Interrupt-driven use of the DCC* on page H4-6786 and the pseudocode for function `CheckForDCCInterrupts()`.
COMMTX	Out	DTRTX is empty	
PMUEVENT[n:0]	Out	Performance Monitors event bus	See *PMUEVENT bus* on page K2-7652.
DBGNOPWRDWN	Out	Emulate low-power state request	Interface to a power controller. See *Emulating low-power states* on page H6-6811.
DBGPWRUPREQ	Out	Core powerup request	Interface to a power controller. See *Powerup request mechanism* on page H6-6810.
DBGRSTREQ	Out	Warm reset request	Interface to a power controller. See EDPRCR.CWRR.

Table K2-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes
DBGBUSCANCELREQ	Out	Allow asynchronous entry to Debug state	Extension to the bus interface. See EDRCR.CBRRQ.
DBGPWRDUP	In	Core powerup status	Interface to a power controller. See EDPRSR.PU.
DBGROMADDR[n:12]	In	MDRAR_EL1.ROMADDR	*n* depends on the size of the physical address space.
DBGROMADDRV	In	MDRAR_EL1.Valid	-
PRESETDBG	In	External debug reset	-
CPUPORESET	In	Cold reset	-
CORERESET	In	Warm reset	-
PSELDBG	In	Debug APB slave port	For details see *AMBA APB3*. Arm recommends a single slave port for all integrated debug components. **PADDRDBG31** distinguishes memory-mapped and Debug Access Port accesses: **0** Memory-mapped access **1** Debug Access Port access If ARMv8.4-Debug is implemented, **PPROTDBG[1]** distinguishes between Secure and Non-secure accesses.
PENABLEDBG	In		
PWRITEDBG	In		
PRDATADBG[31:0]	Out		
PWDATADBG[31:0]	In		
PADDRDBG[n:2][a]	In		
PREADYDBG	Out		
PSLVERRDBG	Out		
PCLKDBG	In		
PCLKENDBG	In		
PPROTDBG[1]	In		
CTICHIN	In	CoreSight channel interface	For details, see the *Arm® CoreSight™ Architecture Specification*. The ACK signals are not required if the channel interface is synchronous.
CTICHOUTACK	In		
CTICHOUT	Out		
CTICHINACK	Out		
CTIIRQ	Out	CTI interrupt, see *Description and allocation of CTI triggers* on page H5-6797	Implements a handshake for an edge-sensitive interrupt.
CTIIRQACK	In

K2.1.1 EDBGRQ and DBGACK

EDBGRQ is an IMPLEMENTATION DEFINED means of generating the External Debug Request debug event described in *External Debug Request debug event* on page H3-6761.

The PE asserts **DBGACK** when the PE is in Debug state. The PE might also include variants of this signal:

DBGTRIGGER

Asserted by the PE when it commits to entering Debug state.

DBGCPUDONE

Asserted by the PE when it has completed all Non-debug state memory accesses and Debug state entry is complete. **DBGCPUDONE** indicates that memory accesses issued by the PE result from operations originating from debugger commands.

In previous architecture versions, these signals provide an interface between the PE and cross-trigger logic. In Armv8, the architectural Cross-Trigger Interface provides this functionality for external debuggers.

K2.1.2 Secure and Non-secure views of the debug registers

If ARMv8.4-Debug is implemented, the external debug interface has views of Secure and Non-secure debug registers. The DAP is must ensure that accesses are made only when permitted. The Arm debug interface describes a standard APB-AP programmers model for APB4 which signals Secure and Non-secure accesses on the **PPROTDBG[1]** signal, and is recommended for new designs.

If ARMv8.4-Debug is implemented, and an APB-AP implements an APB3 master port, which does not support Secure and Non-secure views, Arm recommends that the following is implemented:

- If **SPIDEN** is HIGH and **DBGEN** is HIGH, all external debug accesses area treated as Secure.
- If either **SPIDEN** is LOW or **DBGEN** is LOW, all external debug accesses are treated as Non-secure.

If the PE APB slave port is APB4, this might be implemented by, for example, fixing **PPROTDBG[1]** to the inverse of (**SPIDEN** & **DBGEN**) when bridging from APB3 to APB4.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K2.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. Arm recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. Arm recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSELR multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact Arm.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K2.3 Recommended authentication interface

An implementation of the Armv8 architecture must support debug authentication described in *Required debug authentication* on page H1-6702.

The details of the debug authentication interface are IMPLEMENTATION DEFINED, but Arm recommends the use of the CoreSight interface, which includes the following signals for external debug authentication:

- **DBGEN**.
- **SPIDEN**.

If ARMv8.4-Debug is not implemented, Arm also recommends using the following signals:

- **NIDEN**.
- **SPNIDEN**.

Arm recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted Secure debug authentication if either:

- EL3 is using AArch32 and SDCR.SPD == `0b00`.
- Secure EL1 is using AArch32 and MDCR_EL3.SPD32 == `0b00`.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. Arm recommends that any Trace extension has the same authentication interface as the PE it is connected to.

If ARMv8.4-Debug and CoreSight ETR are both implemented, the ETR has an independent **DBGEN** signal that must be tied HIGH to enable self-hosted use of trace.

Table K2-2 shows the debug authentication pseudocode functions and the recommended implementations.

Table K2-2 Recommended implementation of debug enable pseudocode functions

Pseudocode function	Description	Implementation
`AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()`	Secure invasive self-hosted debug enabled in AArch32 state (legacy)	(**DBGEN** AND **SPIDEN**)
`ExternalSecureNoninvasiveDebugEnabled()`[a]	Secure non-invasive debug enabled	(**DBGEN** OR **NIDEN**[b]) AND (**SPIDEN** OR **SPNIDEN**[c])
`ExternalSecureInvasiveDebugEnabled()`	Secure invasive debug enabled	(**DBGEN** AND **SPIDEN**)
`ExternalNoninvasiveDebugEnabled()`[d]	Non-secure non-invasive debug enabled	(**DBGEN** OR **NIDEN**[b])
`ExternalInvasiveDebugEnabled()`	Non-secure invasive debug enabled	**DBGEN**

a. If ARMv8.4-Debug is implemented, `ExternalSecureNoninvasiveDebugEnabled()` == `ExternalSecureInvasiveDebugEnabled()`.
b. If ARMv8.4-Debug is implemented, the **NIDEN** signal is not implemented.
c. If ARMv8.4-Debug is implemented, the **SPNIDEN** signal is not implemented.
d. If ARMv8.4-Debug is implemented, `ExternalNoninvasiveDebugEnabled()` == TRUE.

K2.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from `0xF00` upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but Arm recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from `0xEFC` downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from `0xE80` to `0xEFC` for this purpose.

K2.4.1 CoreSight interface register map

Table K2-3 shows the external management register maps for the following registers:

ED These are the external debug register.

CTI These are the Cross-trigger interface registers.

PMU These are the Performance Monitors registers.

Table K2-3 CoreSight interface register map

Offset	Mnemonic			Name
	ED	CTI	PMU	
`0xF00`	EDITCTRL	CTIITCTRL	PMITCTRL	Integration Model Control registers
`0xF04-0xF9C`	-	-	-	Reserved, RES0
`0xFA0`	DBGCLAIMSET_EL1[a]	CTICLAIMSET[b]	-	CLAIM Tag Set registers
`0xFA4`	DBGCLAIMCLR_EL1[a]	CTICLAIMCLR[b]	-	CLAIM Tag Clear registers
`0xFA8`	EDDEVAFF0[a]	CTIDEVAFF0[c]	PMDEVAFF0	Device Affinity registers

Table K2-3 CoreSight interface register map (continued)

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xFF0	EDCIDR0	CTICIDR0	PMCIDR0	Component ID registers
0xFF4	EDCIDR1	CTICIDR1	PMCIDR1	
0xFF8	EDCIDR2	CTICIDR2	PMCIDR2	
0xFFC	EDCIDR3	CTICIDR3	PMCIDR3	

a. This register must always be implemented, regardless of whether the component is CoreSight compliant.
b. If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
c. If the CTI implements CTIv1, this register is not implemented. See the register description for details.
d. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.
e. PMDEVID is implemented only from Armv8.2 or if ARMv8.2-PCSample is implemented, otherwise its offset is RES0.

K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, Table K2-4 on page K2-7657, Table K2-5 on page K2-7658, and Table K2-6 on page K2-7659 show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see *External debug interface register access permissions summary* on page H8-6837.

Note

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

Table K2-4 on page K2-7657, Table K2-5 on page K2-7658, and Table K2-6 on page K2-7659 include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in *Reserved and unallocated registers* on page H8-6837 does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See *Register access permissions for memory-mapped accesses* on page H8-6832.

When `HaveSecureExtDebugView()` == TRUE, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

The terms in Table K2-4 on page K2-7657, Table K2-5 on page K2-7658, and Table K2-6 on page K2-7659 are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

Conditions This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

Off EDPRSR.PU == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If debug power is off, then all external debug interface accesses return an error.

DLK If the OS Double Lock is implemented and `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.

OSLK OSLSR.OSLK == 1. The OS Lock is locked.

Default This provides the default access permissions, if there are no conditions that prevent access to the register.

SLK This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-6832. For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO This means that the register or field is read-only.

RW This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

RC This means that the bit clears to 0 after a read.

(SE) This means that accesses to this register have indirect write side effects. A side effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

WO This means that the register or field is write-only.

WI This means that the register or field ignores writes.

IMP DEF This means that the access permissions are IMPLEMENTATION DEFINED.

Table K2-4 External debug interface access permissions, CoreSight registers (debug)

Table K2-6 External debug interface access permissions, CoreSight registers (PMU) (continued)

Offset	Register	Domain	Domain if ARMv8.3-DoPD is implemented	Conditions (priority left to right)			Default	SLK
				Off	DLK	OSLK		
0xFD4-0xFDC	Reserved	Debug		-	-	-	RES0	-
0xFE0	PMPIDR0	Debug	Core	Error in Core domain			RO	-
0xFE4	PMPIDR1	Debug	Core	Error in Core domain			RO	-
0xFE8	PMPIDR2	Debug	Core	Error in Core domain			RO	-
0xFEC	PMPIDR3	Debug	Core	Error in Core domain			RO	-
0xFF0	PMCIDR0	Debug	Core	Error in Core domain			RO	-
0xFF4	PMCIDR1	Debug	Core	Error in Core domain			RO	-
0xFF8	PMCIDR2	Debug	Core	Error in Core domain			RO	-
0xFFC	PMCIDR3	Debug	Core	Error in Core domain			RO	-

a. Implemented from Armv8.2, or if ARMv8.2-PCSample is implemented. Otherwise this location is RES0.

K2.4.3 Management register resets

Table K2-7 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID{n}, DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table K2-7 shows a summary of the management register resets.

Table K2-7 Management register resets

Register	Reset domain	Field	Value	Description
CTIITCTRL EDITCTRL PMITCTRL	IMPLEMENTATION DEFINED	IME	0	Integration mode enable
DBGCLAIMCLR_EL1	Cold reset	CLAIM	0x00	CLAIM tags
CTICLAIMCLR	External debug	CLAIM	0x00000000	
CTILSR[a] EDLSR[a] PMLSR[a]	If ARMv8.3-DoPD is implemented, reset by Cold reset, otherwise External debug.	SLK	1	Software Lock

a. Only if the OPTIONAL Software Lock is implemented

K2.4.4 About the Peripheral identification scheme

The Peripheral Identification scheme provides the standard information required by all components that conform to the *Arm® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2*, that implements the CoreSight identification scheme. They identify a peripheral in a particular namespace. For more information, see the *Arm® CoreSight™ Architecture Specification*.

Table K2-8 lists the Peripheral ID Registers that make up the Peripheral Identification scheme for each component.

Table K2-8 Peripheral Identification Registers

		Reference		
Register offset	**Description**	**External Debug**	**CTI**	**Performance Monitors**
0xFD0	Peripheral ID4	EDPIDR4	CTIPIDR4	PMPIDR4
0xFD4	Reserved for Peripheral ID5	-	-	-
0xFD8	Reserved for Peripheral ID6	-	-	-
0xFDC	Reserved for Peripheral ID7	-	-	-
0xFE0	Peripheral ID0	EDPIDR0	CTIPIDR0	PMPIDR0
0xFE4	Peripheral ID1	EDPIDR1	CTIPIDR1	PMPIDR1
0xFE8	Peripheral ID2	EDPIDR2	CTIPIDR2	PMPIDR2
0xFEC	Peripheral ID3	EDPIDR3	CTIPIDR3	PMPIDR3

Figure K2-2 shows the register field allocation scheme for the Peripheral ID Registers.

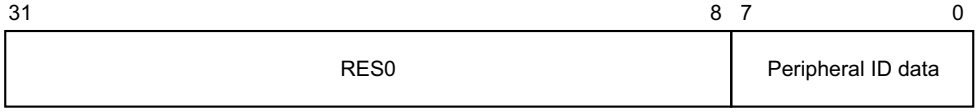

Figure K2-2 Peripheral ID register format

Software can consider the eight Peripheral ID Registers as defining a single 64-bit Peripheral ID, as shown in Figure K2-3.

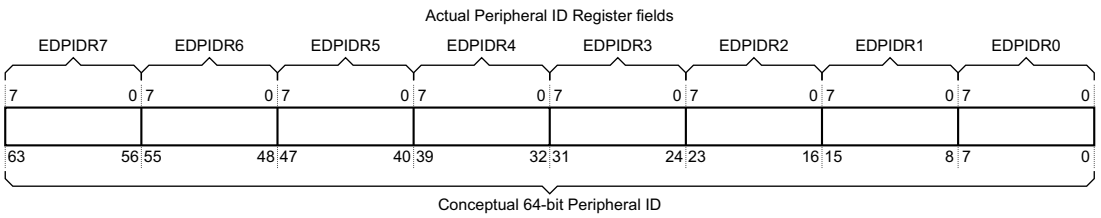

Figure K2-3 Mapping between Peripheral ID Registers and a 64-bit Peripheral ID Value

Figure K2-3 shows the fields in the 64-bit Peripheral ID value, and includes the field values for fields that:

- Have fixed values, including the bits that are reserved.
- Have fixed values in an implementation that is designed by Arm.

For more information about the fields and their values see Table K2-9 on page K2-7662.

Non-Confidential

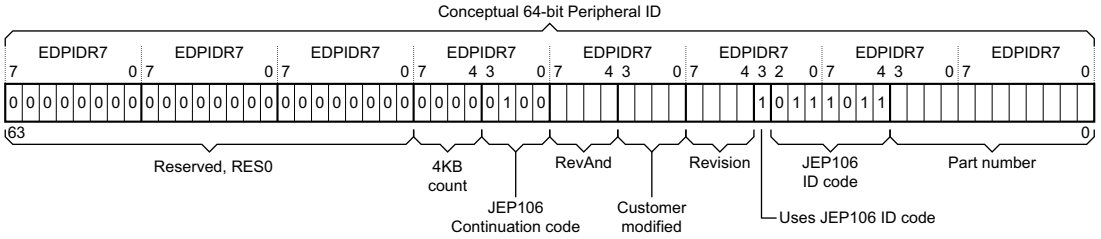

Figure K2-4 Peripheral ID fields, with values for a implementation designed by ARM

Table K2-9 shows the fields in the Peripheral ID.

Table K2-9 Fields in the Peripheral Identification Registers

Name	Size	Description	Registers
4KB count	4 bits	Log2 of the number of 4KB blocks occupied by the implementation.	EDPIDR4 CTIPIDR4 PMPIDR4
JEP106 code	4+7 bits	Identifies the designer of the implementation. This value consists of: • A 4-bit continuation code, also described as the bank number. • A 7-bit identification code. For implementations designed by Arm, the continuation code is 0x4, indicating bank 5, and the identity code is 0x3B.	EDPIDR1, EDPIDR2, EDPIDR4 CTIPIDR1, CTIPIDR2, CTIPIDR4 PMPIDR1, PMPIDR2, PMPIDR4
RevAnd	4 bits	Manufacturing revision number. Indicates a late modification to the implementation, usually as a result of an *Engineering Change Order* (ECO). This field starts at `0x0` and is incremented by the integrated circuit manufacturer on metal fixes.	EDPIDR3 CTIPIDR3 PMPIDR3
Customer modified	4 bits	Indicates an endorsed modification to the implementation. If the system designer cannot modify the implementation supplied by the implementation designer then this field is RES0.	EDPIDR3 CTIPIDR3 PMPIDR3
Revision	4 bits	Revision number for the implementation. Starts at `0x0` and increments by 1 at both major and minor revisions.	EDPIDR2 CTIPIDR2 PMPIDR2
Uses JEP106 ID code	1 bit	This bit is set to 1 when a JEP106 identification code is used. This bit must be 1 on all Armv8 implementations.	EDPIDR2 CTIPIDR2 PMPIDR2
Part number	12 bits	Part number for the implementation. Each organization designing to the Arm Debug architecture specification keeps its own part number list.	EDPIDR0, EDPIDR1 CTIPIDR0, CTIPIDR1 PMPIDR0, PMPIDR1

A component is identified uniquely by the combination of the following fields:

- JEP106 continuation code.
- JEP106 identity code.
- Part number.
- Revision.
- Customer Modified.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- RevAnd.

For components with a *Component class* of 0x9, Debug component, indicated by the Component Identification Registers, multiple components can have the same Part number, provided each component has a different CoreSight *Device type*. However, Arm strongly recommends that each device has a unique Part number. For more information:

- About the Component Identification Registers, see *About the Component Identification scheme*.
- About the CoreSight Device type, see EDDEVTYPE, CTIDEVTYPE, or PMDEVTYPE.
- About CoreSight components and their identification, see the *Arm® Debug Interface Architecture Specification*.

Allocating revisions and part numbers

Within the Peripheral Identification registers, the allocation of major and minor revisions, part numbers, and customer-modified fields is IMPLEMENTATION DEFINED, with the following set of restrictions so that:

- The REVISION field must increase monotonically with revisions.

  Note

  Arm recommends that the REVISION field is updated for each update to the RTL, regardless of whether this is a major or minor update.

- The REVAND field should increase monotonically with revisions.

  Note

  Arm recommends that the REVAND field is used only for post-release changes. For example, those due to engineering change order (ECO) fixes related to the debug component of the processor.

- The PART field must have a degree of uniqueness:
  - Two component designs can have the same part number so long as they are sub-components of the same part and the programmers' model for the part has the means to disambiguate sub-components.
  - Otherwise, two component designs must have unique part numbers.

The DEVARCH (if implemented) or DEVTYPE (otherwise) register provides the means to disambiguate sub-components of the Debug Architecture.

A ROM table has no DEVTYPE or DEVARCH register. However, if it is the only CLASS 0x1 component in a processor cluster, it can still be disambiguated.

Multiple instances of the same component design have the same part number.

K2.4.5 About the Component Identification scheme

The Component Identification Registers identify the processor as an Arm Debug Interface v5 component. For more information, see the *Arm® Debug Interface Architecture Specification* and the *Arm® CoreSight™ Architecture Specification*.

The Component Identification Registers occupy the last four words of the 4KB block of debug registers.

Table K2-10 Component Identification Registers

Appendix K3
Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the Arm recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following sections:

- *Arm recommendations for IMPLEMENTATION DEFINED event numbers* on page K3-7666.
- *Summary of events for exceptions taken to an Exception level using AArch64* on page K3-7681.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K3.1 Arm recommendations for IMPLEMENTATION DEFINED event numbers

These are the Arm recommendations for the use of the IMPLEMENTATION DEFINED event numbers. Arm does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.

Table K3-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers

Event number	Event mnemonic	Description
0x0040	L1D_CACHE_RD	Attributable Level 1 data cache access, read
0x0041	L1D_CACHE_WR	Attributable Level 1 data cache access, write
0x0042	L1D_CACHE_REFILL_RD[a]	Attributable Level 1 data cache refill, read
0x0043	L1D_CACHE_REFILL_WR[a]	Attributable Level 1 data cache refill, write
0x0044	L1D_CACHE_REFILL_INNER	Attributable Level 1 data cache refill, inner
0x0045	L1D_CACHE_REFILL_OUTER	Attributable Level 1 data cache refill, outer
0x0046	L1D_CACHE_WB_VICTIM	Attributable Level 1 data cache Write-Back, victim
0x0047	L1D_CACHE_WB_CLEAN	Level 1 data cache Write-Back, cleaning and coherency
0x0048	L1D_CACHE_INVAL	Attributable Level 1 data cache invalidate
0x0049-0x004B	-	Reserved
0x004C	L1D_TLB_REFILL_RD[a]	Attributable Level 1 data TLB refill, read
0x004D	L1D_TLB_REFILL_WR[a]	Attributable Level 1 data TLB refill, write
0x004E	L1D_TLB_RD	Attributable Level 1 data or unified TLB access, read
0x004F	L1D_TLB_WR	Attributable Level 1 data or unified TLB access, write
0x0050	L2D_CACHE_RD	Attributable Level 2 data cache access, read
0x0051	L2D_CACHE_WR	Attributable Level 2 data cache access, write
0x0052	L2D_CACHE_REFILL_RD[a]	Attributable Level 2 data cache refill, read
0x0053	L2D_CACHE_REFILL_WR[a]	Attributable Level 2 data cache refill, write
0x0054-0x0055	-	Reserved
0x0056	L2D_CACHE_WB_VICTIM	Attributable Level 2 data cache Write-Back, victim
0x0057	L2D_CACHE_WB_CLEAN	Level 2 data cache Write-Back, cleaning and coherency
0x0058	L2D_CACHE_INVAL	Attributable Level 2 data cache invalidate
0x0059-0x005B	-	Reserved
0x005C	L2D_TLB_REFILL_RD[a]	Attributable Level 2 data or unified TLB refill, read
0x005D	L2D_TLB_REFILL_WR[a]	Attributable Level 2 data or unified TLB refill, write

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x005E	L2D_TLB_RD	Attributable Level 2 data or unified TLB access, read
0x005F	L2D_TLB_WR	Attributable Level 2 data or unified TLB access, write
0x0060	BUS_ACCESS_RD	Bus access, read
0x0061	BUS_ACCESS_WR	Bus access, write
0x0062	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable
0x0063	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable
0x0064	BUS_ACCESS_NORMAL	Bus access, normal
0x0065	BUS_ACCESS_PERIPH	Bus access, peripheral
0x0066	MEM_ACCESS_RD	Data memory access, read
0x0067	MEM_ACCESS_WR	Data memory access, write
0x0068	UNALIGNED_LD_SPEC	Unaligned access, read
0x0069	UNALIGNED_ST_SPEC	Unaligned access, write
0x006A	UNALIGNED_LDST_SPEC	Unaligned access
0x006B	-	Reserved
0x006C	LDREX_SPEC	Exclusive operation speculatively executed, LDREX or LDX
0x006D	STREX_PASS_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x006E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, STREX or STX fail
0x006F	STREX_SPEC	Exclusive operation speculatively executed, STREX or STX
0x0070	LD_SPEC	Operation speculatively executed, load
0x0071	ST_SPEC	Operation speculatively executed, store
0x0072	LDST_SPEC	Operation speculatively executed, load or store
0x0073	DP_SPEC	Operation speculatively executed, integer data processing
0x0074	ASE_SPEC	Operation speculatively executed, Advanced SIMD instruction
0x0075	VFP_SPEC	Operation speculatively executed, floating-point instruction
0x0076	PC_WRITE_SPEC	Operation speculatively executed, software change of the PC
0x0077	CRYPTO_SPEC	Operation speculatively executed, Cryptographic instruction
0x0078	BR_IMMED_SPEC	Branch speculatively executed, immediate branch
0x0079	BR_RETURN_SPEC	Branch speculatively executed, procedure return
0x007A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch
0x007B	-	Reserved
0x007C	ISB_SPEC	Barrier speculatively executed, ISB
0x007D	DSB_SPEC	Barrier speculatively executed, DSB

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x007E	DMB_SPEC	Barrier speculatively executed, DMB
0x007F	CSDB_SPEC	Barrier speculatively executed, CSDB
0x0080	-	Reserved
0x0081	EXC_UNDEF	Exception taken, Other synchronous
0x0082	EXC_SVC	Exception taken, Supervisor Call
0x0083	EXC_PABORT	Exception taken, Instruction Abort
0x0084	EXC_DABORT	Exception taken, Data Abort and SError
0x0085	-	Reserved
0x0086	EXC_IRQ	Exception taken, IRQ
0x0087	EXC_FIQ	Exception taken, FIQ
0x0088	EXC_SMC	Exception taken, Secure Monitor Call
0x0089	-	Reserved
0x008A	EXC_HVC	Exception taken, Hypervisor Call
0x008B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not *Taken locally*[b]
0x008C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not *Taken locally*[b]
0x008D	EXC_TRAP_OTHER	Exception taken, Other traps not *Taken locally*[b]
0x008E	EXC_TRAP_IRQ	Exception taken, IRQ not *Taken locally*[b]
0x008F	EXC_TRAP_FIQ	Exception taken, FIQ not *Taken locally*[b]
0x0090	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire
0x0091	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release
0x0092-0x009F	-	Reserved
0x00A0	L3D_CACHE_RD	Attributable Level 3 data or unified cache access, read
0x00A1	L3D_CACHE_WR	Attributable Level 3 data or unified cache access, write
0x00A2	L3D_CACHE_REFILL_RD[a]	Attributable Level 3 data or unified cache refill, read
0x00A3	L3D_CACHE_REFILL_WR[a]	Attributable Level 3 data or unified cache refill, write
0x00A4-0x00A5	-	Reserved
0x00A6	L3D_CACHE_WB_VICTIM	Attributable Level 3 data or unified cache Write-Back, victim
0x00A7	L3D_CACHE_WB_CLEAN	Attributable Level 3 data or unified cache Write-Back, cache clean
0x00A8	L3D_CACHE_INVAL	Attributable Level 3 data or unified cache access, invalidate

a. For more information, see *Relationship between REFILL events and associated access events* on page K3-7679.
b. The Glossary defines the term *Taken locally*. See also *Exception levels* on page D1-2268 for more information.

0x0040, L1D_CACHE_RD, Attributable Level 1 data cache access, read

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

If the cache is shared, only events Attributable to this PE are counted. If the cache is not shared, all events are counted.

See also:

- *Attributability* on page D7-2677.
- *Meaningful ratios between common microarchitectural events* on page D7-2720.

0x0041, L1D_CACHE_WR, Attributable Level 1 data cache access, write

This event is similar to Level 1 data cache access, L1D_CACHE, but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x0042, L1D_CACHE_REFILL_RD, Attributable Level 1 data cache refill, read

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

See also *Relationship between REFILL events and associated access events.* on page K3-7679.

0x0043, L1D_CACHE_REFILL_WR, Attributable Level 1 data cache refill, write

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

See also *Relationship between REFILL events and associated access events.* on page K3-7679.

0x0044, L1D_CACHE_REFILL_INNER, Attributable Level 1 data cache refill, inner

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

Note

The boundary between *inner* and *outer* is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

0x0045, L1D_CACHE_REFILL_OUTER, Attributable Level 1 data cache refill, outer

This event is similar to Level 1 data cache refill, L1D_CACHE_REFILL, but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

0x0046, L1D_CACHE_WB_VICTIM, Attributable Level 1 data cache Write-Back, victim

This event is similar to Level 1 data cache Write-Back, L1D_CACHE_WB, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If ARMv8.4-PMU is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x0047, L1D_CACHE_WB_CLEAN, Level 1 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 1 data cache Write-Back, L1D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

Note

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

`0x0048`, **L1D_CACHE_INVAL, Attributable Level 1 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 1 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If ARMv8.4-PMU is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

`0x004C`, **L1D_TLB_REFILL_RD, Attributable Level 1 data TLB refill, read**

This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-read operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

See also *Relationship between REFILL events and associated access events.* on page K3-7679.

`0x004D`, **L1D_TLB_REFILL_WR, Attributable Level 1 data TLB refill, write**

This event is similar to Level 1 data TLB refill, L1D_TLB_REFILL, but the counter counts only memory-write operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

The counter counts DC ZVA as a store instruction.

See also *Relationship between REFILL events and associated access events.* on page K3-7679.

`0x004E`, **L1D_TLB_RD, Attributable Level 1 data or unified TLB access, read**

This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-read operations that cause a TLB access to at least the Level 1 data or unified TLB.

`0x004F`, **L1D_TLB_WR, Attributable Level 1 data or unified TLB access, write**

This event is similar to Level 1 data or unified TLB access, L1D_TLB, but the counter counts only memory-write operations that cause a TLB access to at least the Level 1 data or unified TLB.

`0x0050`, **L2D_CACHE_RD, Attributable Level 2 data cache access, read**

This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

`0x0051`, **L2D_CACHE_WR, Attributable Level 2 data cache access, write**

This event is similar to Attributable Level 2 data cache access, L2D_CACHE, but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

`0x0052`, **L2D_CACHE_REFILL_RD, Attributable Level 2 data cache refill, read**

This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

See also *Relationship between REFILL events and associated access events.* on page K3-7679.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0x0053, L2D_CACHE_REFILL_WR, Attributable Level 2 data cache refill, write

This event is similar to Attributable Level 2 data cache refill, L2D_CACHE_REFILL, but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

See also *Relationship between REFILL events and associated access events.* on page K3-7679.

0x0056, L2D_CACHE_WB_VICTIM, Attributable Level 2 data cache Write-Back, victim

This event is similar to Attributable Level 2 data cache Write-Back, L2D_CACHE_WB, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If ARMv8.4-PMU is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x0057, L2D_CACHE_WB_CLEAN, Level 2 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 2 data cache Write-Back, L2D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted as IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x0058, L2D_CACHE_INVAL, Attributable Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If ARMv8.4-PMU is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x005C, L2D_TLB_REFILL_RD, Attributable Level 2 data or unified TLB refill, read

This event is similar to Attributable Level 2 data or unified TLB refill, L2D_TLB_REFILL, but the counter counts only Attributable memory read operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also *Relationship between REFILL events and associated access events.* on page K3-7679.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0x005D, L2D_TLB_REFILL_WR, Attributable Level 2 data or unified TLB refill, write

This event is similar to Attributable Level 2 data or unified TLB refill, L2D_TLB_REFILL, but the counter counts only Attributable memory write operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also *Relationship between REFILL events and associated access events.* on page K3-7679.

0x005E, L2D_TLB_RD, Attributable Level 2 data or unified TLB access, read

This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory read operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x005F, L2D_TLB_WR, Attributable Level 2 data or unified TLB access, write

This event is similar to Attributable Level 2 data or unified TLB access, L2D_TLB, but the counter counts only Attributable memory write operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x0060, BUS_ACCESS_RD, Bus access, read

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

0x0061, BUS_ACCESS_WR, Bus access, write

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

0x0062, BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

Note

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0063, BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

Note

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

Non-Confidential

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

`0x0064`, **BUS_ACCESS_NORMAL, Bus access, normal**

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

`0x0065`, **BUS_ACCESS_PERIPH, Bus access, peripheral**

This event is similar to Bus access, BUS_ACCESS, but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

`0x0066`, **MEM_ACCESS_RD, Data memory access, read**

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-read operations and SVE memory-read operations that the PE made.

`0x0067`, **MEM_ACCESS_WR, Data memory access, write**

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only memory-write operations and SVE memory-write operations made by the PE.

`0x0068`, **UNALIGNED_LD_SPEC. Unaligned access, read**

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations and unaligned memory-read SVE operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

`0x0069`, **UNALIGNED_ST_SPEC, Unaligned access, write**

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-write operations and unaligned SVE memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

`0x006A`, **UNALIGNED_LDST_SPEC, Unaligned access**

This event is similar to Data memory access, MEM_ACCESS, but the counter counts only unaligned memory-read operations, unaligned memory-write operations, unaligned memory-read SVE operations, and unaligned memory-write SVE operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

`0x006C`, **LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive**

The counter counts Load-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x006D`, **STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass**

The counter counts Store-Exclusive instructions speculatively executed that completed a write.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.

`0x006E`, **STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail**

The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the LDREX_SPEC event.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0x006F, STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive

The counter counts Store-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the LDREX_SPEC event.

Arm recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the LDREX_SPEC event.

0x0070, LD_SPEC, Operation speculatively executed, load

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to memory-reading instructions and operations due to memory-reading SVE instructions, as defined by the LD_RETIRED event.

The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0071, ST_SPEC, Operation speculatively executed, store

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to memory-writing instructions and operations due to memory-writing SVE instructions, as defined by the ST_RETIRED event.

The counter counts DC ZVA as a store operation.

The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0072, LDST_SPEC, Operation speculatively executed, load or store

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to memory-reading instructions, operations due to memory-writing instructions, operations due to memory-reading SVE instructions and operations due to memory-writing SVE instructions as defined by the LD_RETIRED and ST_RETIRED events.

The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0073, DP_SPEC, Operation speculatively executed, integer data processing

This event is similar to Operation speculatively executed, INST_SPEC, but counts only operations due to integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, *Data processing - immediate* on page C3-214 and *Data processing - register* on page C3-219.
- In AArch32 state, *Data-processing instructions* on page F1-3870.

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, *System register instructions* on page C3-192, *System instructions* on page C3-192, and *Hint instructions* on page C3-193.
- In AArch32 state, *PSTATE and banked register access instructions* on page F1-3878, *Banked register access instructions* on page F1-3878, *Miscellaneous instructions* on page F1-3883, other than ISB and preloads, and *System register access instructions* on page F1-3887, other than LDC and STC instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBs do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of Speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but Arm recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - `FMOV` (general).
- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
  - `DUP` (general).
  - `SMOV`.
  - `UMOV`.
  - `INS` (general).
- For AArch32 state:
  - `VDUP` (general-purpose register) and all `VMOV` instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
  - `VMRS`.
  - `VMSR`.

`0x0074`, ASE_SPEC, Operation speculatively executed, Advanced SIMD

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in *Data processing - SIMD and floating-point* on page C3-227.
- For AArch32 state, *Advanced SIMD data-processing instructions* on page F1-3891.

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than `PMULL`, in AArch64 state.
- `VMULL`, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, `PMULL`, and in AArch32 state, `VMULL` are counted as Advanced SIMD operations.

The definition of Speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

`0x0075`, VFP_SPEC, Operation speculatively executed, floating-point

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to floating-point data-processing instructions, see:

- In AArch64 state, only the scalar floating-point operations listed in *Data processing - SIMD and floating-point* on page C3-227.

  Note

  This event does not count the SIMD floating-point operations listed in *Data processing - SIMD and floating-point* on page C3-227.

- In AArch32 state, *Floating-point data-processing instructions* on page F1-3901.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, `FCVT{<mode>}`, `UCVTF`, and `SCVTF`.
- In AArch32 state, `VCVT<mode>`(floating-point), `VCVT`, `VCVTT`, and `VCVTB`.

The definition of Speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

`0x0076`, PC_WRITE_SPEC, Operation speculatively executed, software change of the PC

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see *Common event numbers* on page D7-2694.

The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

See also PC_WRITE_RETIRED.

`0x0077`, CRYPTO_SPEC, Operation speculatively executed, Cryptographic instruction

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only operations due to Cryptographic instructions, except `PMULL` and `VMULL`, see *The Cryptographic Extension* on page C3-247.

The definition of Speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

`0x0078`, BR_IMMED_SPEC, Branch speculatively executed, immediate branch

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see *Common event numbers* on page D7-2694.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

See also BR_IMMED_RETIRED.

`0x0079`, BR_RETURN_SPEC, Branch speculatively executed, procedure return

The counter counts procedure return instructions speculatively executed. Defined by the BR_RETURN_RETIRED event.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

See also BR_RETURN_RETIRED.

`0x007A`, BR_INDIRECT_SPEC, Branch speculatively executed, indirect branch

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

`0x007C`, ISB_SPEC, Barrier speculatively executed, `ISB`

The counter counts Instruction Synchronization Barrier instructions speculatively executed, including CP15ISB.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x007D`, **DSB_SPEC, Barrier speculatively executed,** `DSB`

The counter counts data synchronization barrier instructions speculatively executed, including CP15DSB, SSBB and PSSBB.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

`0x007E`, **DMB_SPEC, Barrier speculatively executed,** `DMB`

The counter counts data memory barrier instructions speculatively executed, including CP15DSB. It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

`007F`, **CSDB_SPEC, Barrier speculatively executed, CSDB**

If ARMv8.5-PMU is implemented, the counter counts control speculation barrier instructions speculatively executed.

The definition of Speculatively executed is IMPLEMENTATION DEFINED.

`0x0081`, **EXC_UNDEF, Exception taken, other synchronous**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only those exceptions *Taken locally* that are not counted as:

- Exception taken, Supervisor Call (EXC_SVC).
- Exception taken, Secure Monitor Call (EXC_SMC).
- Exception taken, Hypervisor Call (EXC_HVC).
- Exception taken, Instruction Abort (EXC_PABORT).
- Exception taken, Data Abort or SError (EXC_DABORT).
- Exception taken, IRQ (EXC_IRQ).
- Exception taken, FIQ (EXC_FIQ).

`0x0082`, **EXC_SVC, Exception taken, Supervisor Call**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Supervisor Call exceptions that are *Taken locally*.

`0x0083`, **EXC_PABORT, Exception taken, Instruction Abort**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions that are *Taken locally*.

`0x0084`, **EXC_DABORT, Exception taken, Data Abort or SError**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions *Taken locally*.

`0x0086`, **EXC_IRQ, Exception taken, IRQ**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions that are *Taken locally*, including Virtual IRQ exceptions.

`0x0087`, **EXC_FIQ, Exception taken, FIQ**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions that are *Taken locally*, including Virtual FIQ exceptions.

`0x0088`, **EXC_SMC, Exception taken, Secure Monitor Call**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Secure Monitor Call exceptions. The counter does not increment on `SMC` instructions trapped as a Hyp Trap exception.

`0x008A`, **EXC_HVC, Exception taken, Hypervisor Call**

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions *Taken locally* in the hypervisor and those taken as an exception from Non-secure EL1.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0x008B, EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Instruction Abort exceptions not *Taken locally*.

0x008C, EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only Data Abort or SError interrupt exceptions not *Taken locally*.

0x008D, EXC_TRAP_OTHER, Exception taken, other traps not Taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only those traps that are not counted as:

- Exception taken, Secure Monitor Call (EXC_SMC).
- Exception taken, Hypervisor Call (EXC_HVC).
- Exception taken, Instruction Abort not *Taken locally* (EXC_TRAP_PABORT).
- Exception taken, Data Abort or SError not *Taken locally* (EXC_TRAP_DABORT).
- Exception taken, IRQ not *Taken locally* (EXC_TRAP_IRQ).
- Exception taken, FIQ not *Taken locally* (EXC_TRAP_FIQ).

0x008E, EXC_TRAP_IRQ, Exception taken, IRQ not Taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only IRQ exceptions not *Taken locally*.

0x008F, EXC_TRAP_FIQ, Exception taken, FIQ not Taken locally

This event is similar to Exception taken, EXC_TAKEN, but the counter counts only FIQ exceptions not *Taken locally*.

0x0090, RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire

The counter counts memory-read operations with acquire or acquirepc semantics that are speculatively executed.

0x0091, RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release

The counter counts memory-write operations with release semantics that are speculatively executed.

0x00A0, L3D_CACHE_RD, Attributable Level 3 data or unified cache access, read

This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the counter counts only attributable memory read operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A1, L3D_CACHE_WR, Attributable Level 3 data or unified cache access, write

This event is similar to Attributable Level 3 data or unified cache access, L3D_CACHE, but the counter counts only attributable memory write operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A2, L3D_CACHE_REFILL_RD, Attributable Level 3 data or unified cache refill, read

This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL, but the counter counts only attributable memory read operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3cache. See also *Relationship between REFILL events and associated access events.* on page K3-7679

0x00A3, L3D_CACHE_REFILL_WR, Attributable Level 3 data or unified cache refill, write

This event is similar to Attributable Level 3 data or unified cache refill, L3D_CACHE_REFILL, but the counter counts only attributable memory write operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3cache. See also *Relationship between REFILL events and associated access events.* on page K3-7679

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0x00A6, L3D_CACHE_WB_VICTIM, Attributable Level 3 data or unified cache Write-Back, victim

This event is similar to Attributable Level 3 data cache Write-Back, L3D_CACHE_WB, but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

If ARMv8.4-PMU is not implemented, Write-Backs caused by the execution of a cache maintenance instruction are not counted. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether Write-Backs caused by the execution of a cache maintenance instruction are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x00A7, L3D_CACHE_WB_CLEAN, Level 3 data or unified cache Write-Back, cache clean

This event is similar to Attributable Level 3 data cache Write-Back, L3D_CACHE_WB, but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 3 data cache of this PE to the Level 3 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x00A8, L3D_CACHE_INVAL, Attributable Level 3 data or unified cache access, invalidate

The counter counts each invalidation of a cache line in the Level 3 data or unified cache.

The counter does not count events if a cache refill invalidates a line.

If ARMv8.4-PMU is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way. If ARMv8.4-PMU is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

K3.1.1 Relationship between REFILL events and associated access events.

CACHE_REFILL and TLB_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. Table K3-2 shows this correspondence.

Table K3-2 Relationship between REFILL events and associated access events

REFILL event	Access event	Ratio REFILL/Access
0x0042 L1D_CACHE_REFILL_RD	0x0040 L1D_CACHE_RD	Attributable Level 1 cache refill rate, read
0x0043 L1D_CACHE_REFILL_WR	0x0041 L1D_CACHE_WR	Attributable Level 1 cache refill rate, write
0x004C L1D_TLB_REFILL_RD	0x004E L1D_TLB_RD	Attributable Level 1 TLB refill rate, read
0x004D L1D_TLB_REFILL_WR	0x004F L1D_TLB_WR	Attributable Level 1 TLB refill rate, write

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table K3-2 Relationship between REFILL events and associated access events (continued)

REFILL event	Access event	Ratio REFILL/Access
0x0052 L2D_CACHE_REFILL_RD	0x0050 L2D_CACHE_RD	Attributable Level 2 data cache refill rate, read
0x0053 L2D_CACHE_REFILL_WR	0x0051 L2D_CACHE_WR	Attributable Level 2 data cache refill rate, write
0x005C L2D_TLB_REFILL_RD	0x005E L2D_TLB_RD	Attributable Level 2 data TLB refill rate, read
0x005D L2D_TLB_REFILL_WR	0x005F L2D_TLB_WR	Attributable Level 2 data TLB refill rate, write
0x00A2 L3D_CACHE_REFILL_RD	0x00A0 L3D_CACHE_RD	Attributable Level 3 data cache refill rate, read
0x00A3 L3D_CACHE_REFILL_WR	0x00A1 L3D_CACHE_WR	Attributable Level 3 data cache refill rate, write

K3.2 Summary of events for exceptions taken to an Exception level using AArch64

Table K3-3 shows the events for exceptions taken to an Exception level using AArch64.

Table K3-3 Events for exceptions taken to an Exception level using AArch64

ESR.EC	Description		Event number and classification for exceptions	
			Taken locally	Not *Taken locally*
0x00	Unknown or uncategorized		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x01	WFE/WFI traps		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x03	AArch32 MCR/MRC traps on (coproc==0b1111) accesses		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x04	AArch32 MCRR/MRRC traps on (coproc==0b1111) accesses		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x05	AArch32 MCR/MRC traps on (coproc==0b1110) accesses		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x06	AArch32 LDC/STC traps on (coproc==0b1110) accesses		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x07	Advanced SIMD or FP traps		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x08	AArch32 MVFR* and FPSID traps		-	0x008D, EXC_TRAP_OTHER
0x0C	AArch32 MCRR/MRRC traps on (coproc==0b1110) accesses		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x0E	Illegal instruction set state		0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x11	AArch32 SVC		0x0082, EXC_SVC	0x008D, EXC_TRAP_OTHER
0x12	AArch32 HVC that is not disabled		-	0x008A, EXC_HVC
0x13	AArch32 SMC that is not disabled	to EL2	-	0x008D, EXC_TRAP_OTHER
		to EL3	-	0x0088, EXC_SMC
0x15	AArch64 SVC		0x0082, EXC_SVC	0x008D, EXC_TRAP_OTHER
0x16	AArch64 HVC that is not disabled		0x008A, EXC_HVC	0x008A, EXC_HVC

Table K3-3 Events for exceptions taken to an Exception level using AArch64 (continued)

ESR.EC	Description	Event number and classification for exceptions	
		Taken locally	Not *Taken locally*
0x24	Data Abort from below	0x0084, EXC_DABORT	0x008C, EXC_TRAP_DABORT
0x25	Data Abort from current Exception level	0x0084, EXC_DABORT	-
0x26	SP alignment fault exception	0x0084, EXC_DABORT	0x008C, EXC_TRAP_DABORT
0x28	AArch32 FP exception	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x2C	AArch64 FP exception	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x2F	SError interrupt	0x0084, EXC_DABORT	0x008C, EXC_TRAP_DABORT
0x30	Breakpoint from below	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x31	Breakpoint from current Exception level	0x0083, EXC_PABORT	-
0x32	Software step from below	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x33	Software step from current Exception level	0x0083, EXC_PABORT	-
0x34	Watchpoint from below	0x0084, EXC_DABORT	0x008C, EXC_TRAP_DABORT
0x35	Watchpoint from current Exception level	0x0084, EXC_DABORT	-
0x38	AArch32 BKPT instruction	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x3A	AArch32 Vector Catch debug event	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x3C	AArch64 BRK instruction	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
-	IRQ interrupt	0x0086, EXC_IRQ	0x008E, EXC_TRAP_IRQ
-	FIQ interrupt	0x0087, EXC_FIQ	0x008F, EXC_TRAP_FIQ
-	All other values	-	0x008D, EXC_TRAP_OTHER

a. The exception reported with EC 0x1F is IMPLEMENTATION DEFINED, and therefore it is IMPLEMENTATION DEFINED which event counts the exception, except that the event that counts the exception must correctly indicate whether the exception was *Taken locally*.

Note

The Glossary defines the term *Taken locally*, that is used in event definitions in this chapter. See also *Exception levels* on page D1-2268 for more information.

Appendix K4
Recommendations for reporting memory attributes on an interconnect

This appendix describes the Arm recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

- *Arm recommendations for reporting memory attributes on an interconnect* on page K4-7684.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K4.1 Arm recommendations for reporting memory attributes on an interconnect

The Arm architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that Arm strongly recommends, but these recommendations do not form part of the Armv8 architecture.

K4.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the Arm architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, Arm strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early write acknowledgement attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

Effect when memory accesses are forced to be Non-cacheable

Arm also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in *Enabling and disabling the caching of memory accesses* on page D4-2475 for AArch64 and in *Enabling and disabling the caching of memory accesses in AArch32 state* on page G4-5691 for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.

Appendix K5
Additional Information for Implementations of the Generic Timer

This appendix gives additional information about implementations of the Generic Timer. It contains the following sections:

- *Providing a complete set of features in a system level implementation* on page K5-7686.
- *Gray-count scheme for timer distribution scheme* on page K5-7688.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

K5.1 Providing a complete set of features in a system level implementation

As an example system design, using memory-mapped Generic Timer components as described in Chapter I2 *System Level Implementation of the Generic Timer*, the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A CNTCTLBase control frame.
- The following CNTBaseN*N* timer frames:

  Frame 0 Accessible by Non-secure accesses, with second view and virtual capability. This provides the Non-secure EL1&0 timers.

  Frame 1 Accessible by Non-secure accesses, with no second view and no virtual capability. This provides the Non-secure EL2 timers.

  Frame 2 Accessible only by Secure accesses, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
  - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
  - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.

  Frame 3 Accessible only by Secure accesses, with no second view and no virtual capability. This provides the Secure EL3 timers.

  Note

  This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and accessibility as memory pages in the different translation regimes, is as follows:

CNTCTLBase

The control frame. This frame is accessible in both the Secure and Non-secure memory maps, and:
- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase0 The first view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:
- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

CNTEL0Base0

The second view of CNTBase0, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is accessible only in the Non-secure memory map, and:
- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

CNTBase1 The first and only view of the Non-secure EL2 timers. This frame is accessible only in Non-secure memory map, and:
- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CNTBase2 The first view of the Secure EL1&0, or PL1&0 timers.

Note

In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see *Security state, Exception levels, and AArch32 execution privilege* on page G1-5480.

This frame is accessible only in the Secure memory map, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTEL0Base2

The second view of CNTBase2, meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

Note

See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

This frame is accessible only in the Secure memory map, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTBase3 The first and only view of the EL3 timers. This frame is accessible only in the Secure memory map, and:

- When EL3 is using AArch64:
  - In the Secure EL1&0 translation regime, this frame is not accessible.
  - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, this frame is not accessible.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

Note

About the Virtual Memory System Architecture (VMSA) on page D5-2504 describes the VMSAv8-64 translation regimes, and *About VMSAv8-32* on page G5-5720 describes the VMSAv8-32 translation regimes.

K5.2 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

```
Gray[N] = Count[N]
Gray[i] = (XOR(Gray[N:i+1])) XOR Count[i] for N-1 >= i >= 0
Count[i] = XOR(Gray[N:i]) for N >= i >= 0
```

This is for an N+1 bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

Note

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be 2^n, where n is an integer. A switch-over can occur only on the $2n+1$ boundary to avoid losing the Gray-coding property on a switch-over.

Appendix K6
Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the Arm instruction sets, and their *Unified Assembler Language* (UAL) equivalents. It contains the following section:

- *Legacy Instruction Syntax* on page K6-7690.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K6.1 Legacy Instruction Syntax

Early versions of the Arm Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

K6.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K6-1 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

K6.1.3 FCONST

The syntax of FCONST is

```
FCONST<dest>{<c>} <Fd>, #<imm8>
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

where:

`<dest>` Specifies the destination data type. It must be one of:

- `S` Single-precision floating-point.
- `D` Double-precision floating-point.

`<c>` This is an optional field. It specifies the condition under which the instruction is executed. See *Conditional execution* on page F2-3909 for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (`AL`).

`<Fd>` Specifies the destination register. It must be one of:

- `<Dd>` 64-bit name of the SIMD&FP destination register.
- `<Sd>` 32-bit name of the SMID&FP destination register.

`<imm8>` Specifies the immediate value used to generate the floating-point constant.

`FCONSTD{<c>} <Dd>, #<imm8>` maps to `VMOV.F64 <Dd>, #<fpimm>`

`FCONSTS{<c>} <Sd>, #<imm8>` maps to `VMOV.F32 <Sd>, #<fpimm>`

Appendix K7
Address translation examples

This appendix gives examples of address translations using the translation regimes described in Chapter D5 *The AArch64 Virtual Memory System Architecture* and Chapter G5 *The AArch32 Virtual Memory System Architecture*. It contains the following sections:

- *AArch64 Address translation examples* on page K7-7698.
- *AArch32 Address translation examples* on page K7-7710.

Note

This chapter gives examples of translation table lookups for the Armv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in Chapter D5 *The AArch64 Virtual Memory System Architecture* or Chapter G5 *The AArch32 Virtual Memory System Architecture* then the information in Chapter D5 or Chapter G5 must be taken as the definition of the required behavior.

K7.1 AArch64 Address translation examples

Figure D5-1 on page D5-2514 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. *The VMSAv8-64 address translation system* on page D5-2512 describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System registers relevant to MMU operation on page D5-2519 specifies the relevant registers, including the TCR_ELx and TTBR_ELx, or TTBR_ELxs, for each stage of address translation.

For any stage of translation, a TCR_ELx.T*n*SZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is $2^{(64-T\mathit{n}SZ)}$.

This section describes:

- Performing the initial lookup, for an address for which the initial lookup is either:
  - At the highest lookup level used for the appropriate translation granule size.
  - Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

  These descriptions take account of the following cases:
  - The IA size is smaller than the largest size for the translation level, see *Reduced IA width* on page D5-2531.
  - For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see *Concatenated translation tables* on page D5-2532.

  For examples of performing the initial lookup, see *Examples of performing the initial lookup*.
- The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see *Full translation flows for VMSAv8-64 address translation* on page K7-7704.

K7.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

- *Performing the initial lookup using the 4KB translation granule*.
- *Performing the initial lookup using the 16KB granule* on page K7-7700.
- *Performing the initial lookup using the 64KB translation granule* on page K7-7702.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that Table D5-13 on page D5-2537 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D5-2512.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-13 on page D5-2537 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 4KB translation granule* on page K7-7699.
- *Initial lookup at level 1, 4KB translation granule* on page K7-7699.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 4KB granule* on page D5-2537.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D5-13 on page D5-2537 shows, a stage 1 or stage 2 initial lookup at level 0 is required when $39 \le n \le 47$. For these lookups:

- TTBR_ELx[47:(n-35)] specify the translation table base address.
- Bits[n:39] of the input address are bits[(n-36):3] of the descriptor offset in the translation table.

Note

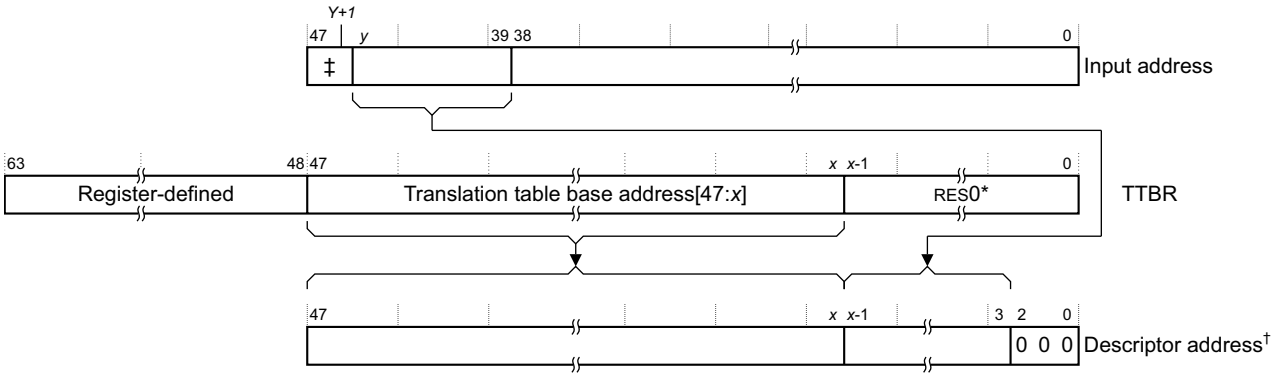
This means that, when the input address width is less than 48 bits

- The size of the translation table is reduced.
- More low-order bits of the TTBR_ELx are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- TTBR_ELx bits[47:10] specify the translation table base address.
- Input address bits[45:39] specify bits[9:3] of the descriptor offset.

Figure K7-1 shows this lookup.



Supported input address range is IA[y:0], $4 \le x \le 12$, $y = x + 35$. When y is 47 the field marked ‡ is absent.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-1 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0

Initial lookup at level 1, 4KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

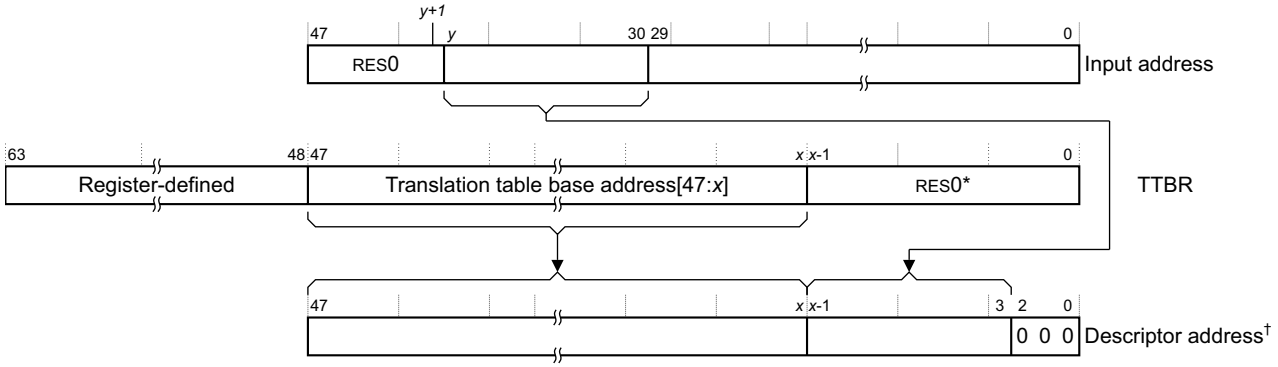
For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D5-13 on page D5-2537 shows, this applies to IA[n:0], where $30 \le n \le 38$. For these lookups:

- There is a single translation table at this level.
- TTBR_ELx[47:(n-26)] specify the translation table base address.
- Bits[n:30] of the input address are bits[(n-27):3] of the descriptor offset in the translation table.

Figure K7-2 on page K7-7700 shows this lookup.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Supported input address range is IA[*y*:0], 4 ≤ *x* ≤ 12, *y* = *x* + 26.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

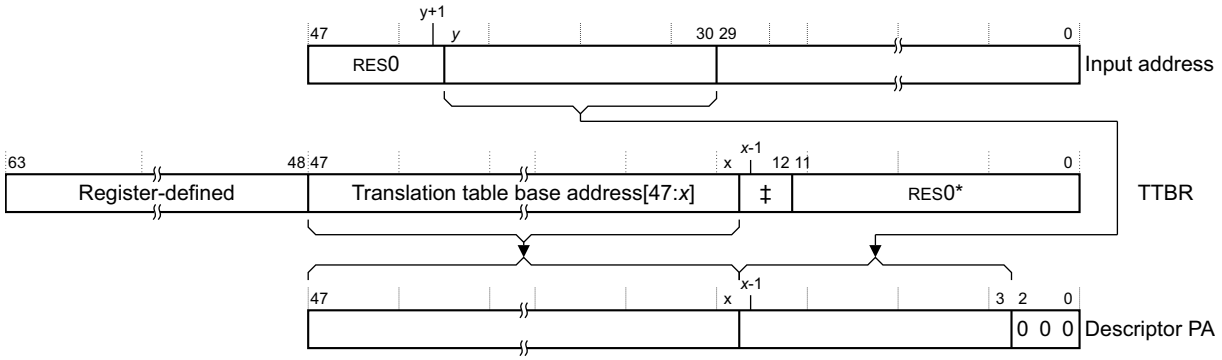
Figure K7-2 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D5-13 on page D5-2537 shows, this applies to IA[*n*:0], where 39 ≤ *n* ≤ 42. For these lookups:

- There are $2^{(n-38)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-38)}$×4KB. This means TTBR_ELx[(*n*-27):12] must be zero.
- TTBR_ELx[47:(*n*-26)] specify the base address of the block of concatenated translation tables.
- Bits[*n*:30] of the input address are bits[(*n*-27):3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-3 shows this lookup.



Supported input address range is IPA[*y*:0], 4 ≤ *x* ≤ 16, *y* = *x* + 26. The field marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-3 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D5-15 on page D5-2541 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D5-2512.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-15 on page D5-2541 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 16KB translation granule*.
- *Initial lookup at level 1, 16KB translation granule*.

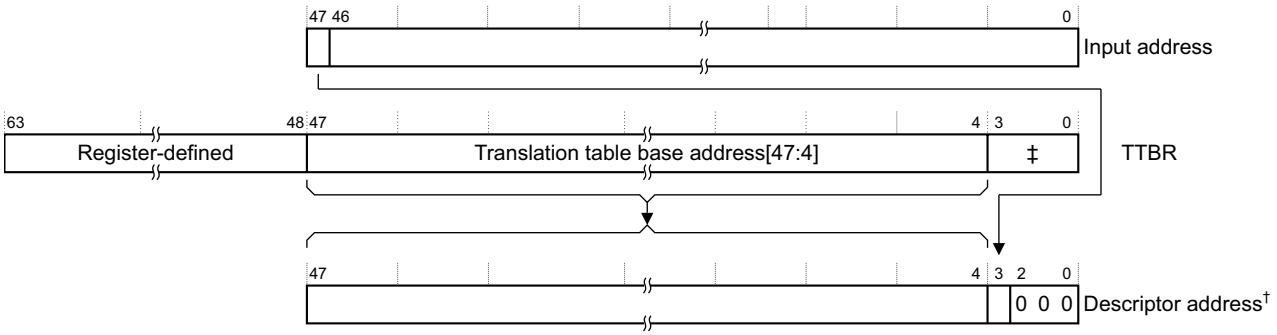
In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 16KB granule* on page D5-2541.

Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D5-14 on page D5-2540 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, IA[47:0]. For this lookup:

- The required translation table has only two entries, meaning its size is 16bytes, and it must be aligned to 16 bytes.
- TTBR_ELx[47:4] specify the translation table base address.
- Bit[47] of the input address is bits[3] of the descriptor offset in the translation table.

Figure K7-4 shows this lookup.



Supported input address range is IA[47:0]. The field marked ‡ is RES0*.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-4 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 0

Initial lookup at level 1, 16KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

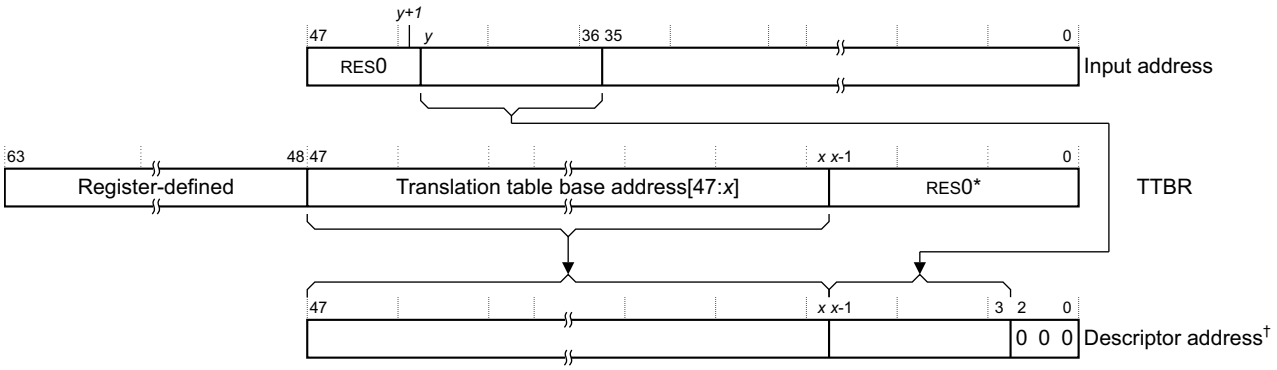
For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D5-15 on page D5-2541 shows, this applies to IA[n:0], where $36 \le n \le 46$. For these lookups:

- There is a single translation table at this level.
- TTBR_ELx[47:(n-32)] specify the translation table base address.
- Bits[n:36] of the input address are bits[(n-33):3] of the descriptor offset in the translation table.

Figure K7-5 on page K7-7702 shows this lookup.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Supported input address range is IA[*y*:0], 4 ≤ *x* ≤ 14, *y* = *x* + 32.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

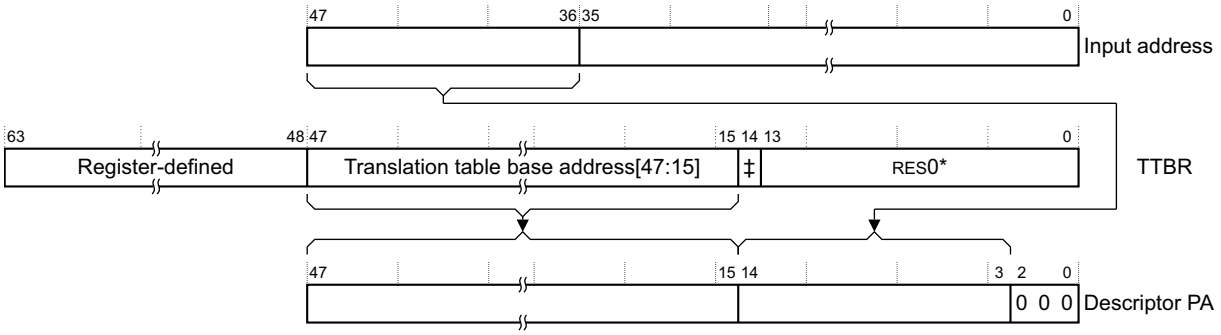
Figure K7-5 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D5-15 on page D5-2541 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2×16KB. This means TTBR_ELx[14] must be zero.
- TTBR_ELx[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K7-6 shows this lookup.



Supported input address range is IPA[47:0]. The bit marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that Table D5-17 on page D5-2545 shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D5-2512.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D5-17 on page D5-2545 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 1, 64KB translation granule*.
- *Initial lookup at level 2, 64KB translation granule*.

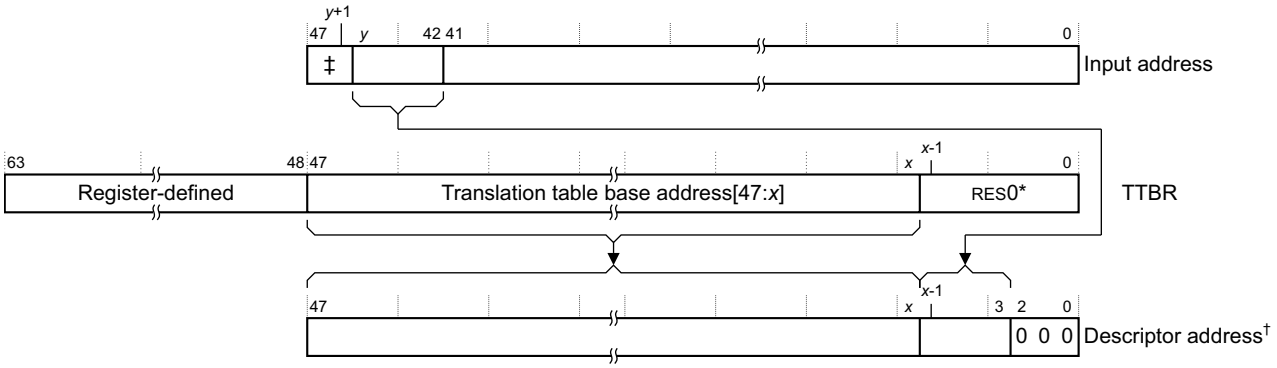
In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 64KB granule* on page D5-2545.

Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D5-17 on page D5-2545 shows, a stage 1 or stage 2 initial lookup at level 1 is required when $42 \le n \le 47$. For these lookups:

- The size of the translation table is $2^{(n-39)}$ bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits[n:42] of the input address are bits[(n-39):3] of the descriptor offset in the translation table.
- Bits[47:(n-38)] of the TTBR_ELx specify the translation table base address.

Figure K7-7 shows this lookup.



Supported input address range is IA[y:0], $4 \le x$ $y = x + 38$. When y is 47 the field marked ‡ is absent.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-7 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1

Initial lookup at level 2, 64KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

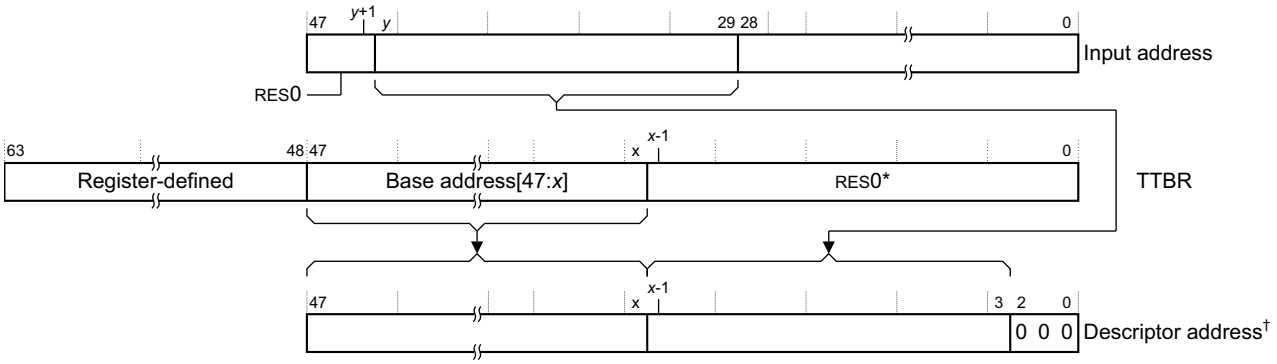
For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D5-17 on page D5-2545 shows, this applies to IA[n:0], where $29 \le n \le 41$. For these lookups:

- There is a single translation table at this level.
- TTBR_ELx[47:(n-25)] of the specify the translation table base address.
- Bits[n:29] of the input address are bits[(n-26):3] of the descriptor offset in the translation table.

Figure K7-8 on page K7-7704 shows this lookup.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Supported input address range is IA[*y*:0]. $4 \le x \le 16$, $y = x + 25$.

† For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

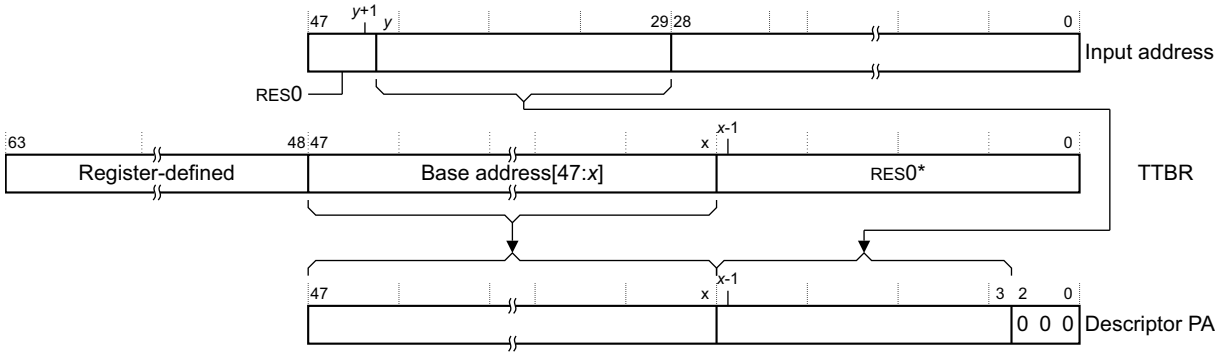
Figure K7-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D5-17 on page D5-2545 shows, this applies to IA[n:0], where $42 \le n \le 45$. For these lookups:

- There are $2^{(n-41)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-41)} \times 64$KB. This means TTBR_ELx[(n-26):16] must be zero.
- TTBR_ELx[47:(n-25)] specify the base address of the block of translation tables.
- Bits[n:42] of the input address are bits[(n-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure K7-9 shows this lookup.



Supported input address range is IPA[*y*:0], $4 \le x \le 20$, $y = x + 25$.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

K7.1.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR_ELx. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Do not have any concatenation of translation tables.
- Cover only the 4KB and the 64KB translation granules.

Examples of performing the initial lookup on page K7-7698 described how either reducing the IA range or concatenating translation tables affects the initial lookup.

Note

Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:

- *The address and properties fields shown in the translation flows*.
- *Full translation flow using the 4KB granule and starting at level 0*.
- *Full translation flow using the 4KB granule and starting at level 1* on page K7-7707.
- *Full translation flow using the 64KB granule and starting at level 1* on page K7-7708.
- *Full translation flow using the 64KB granule and starting at level 2* on page K7-7709.

The address and properties fields shown in the translation flows

For an EL1&0 stage 1 translation, when EL2 is implemented and enabled in the current Security state:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

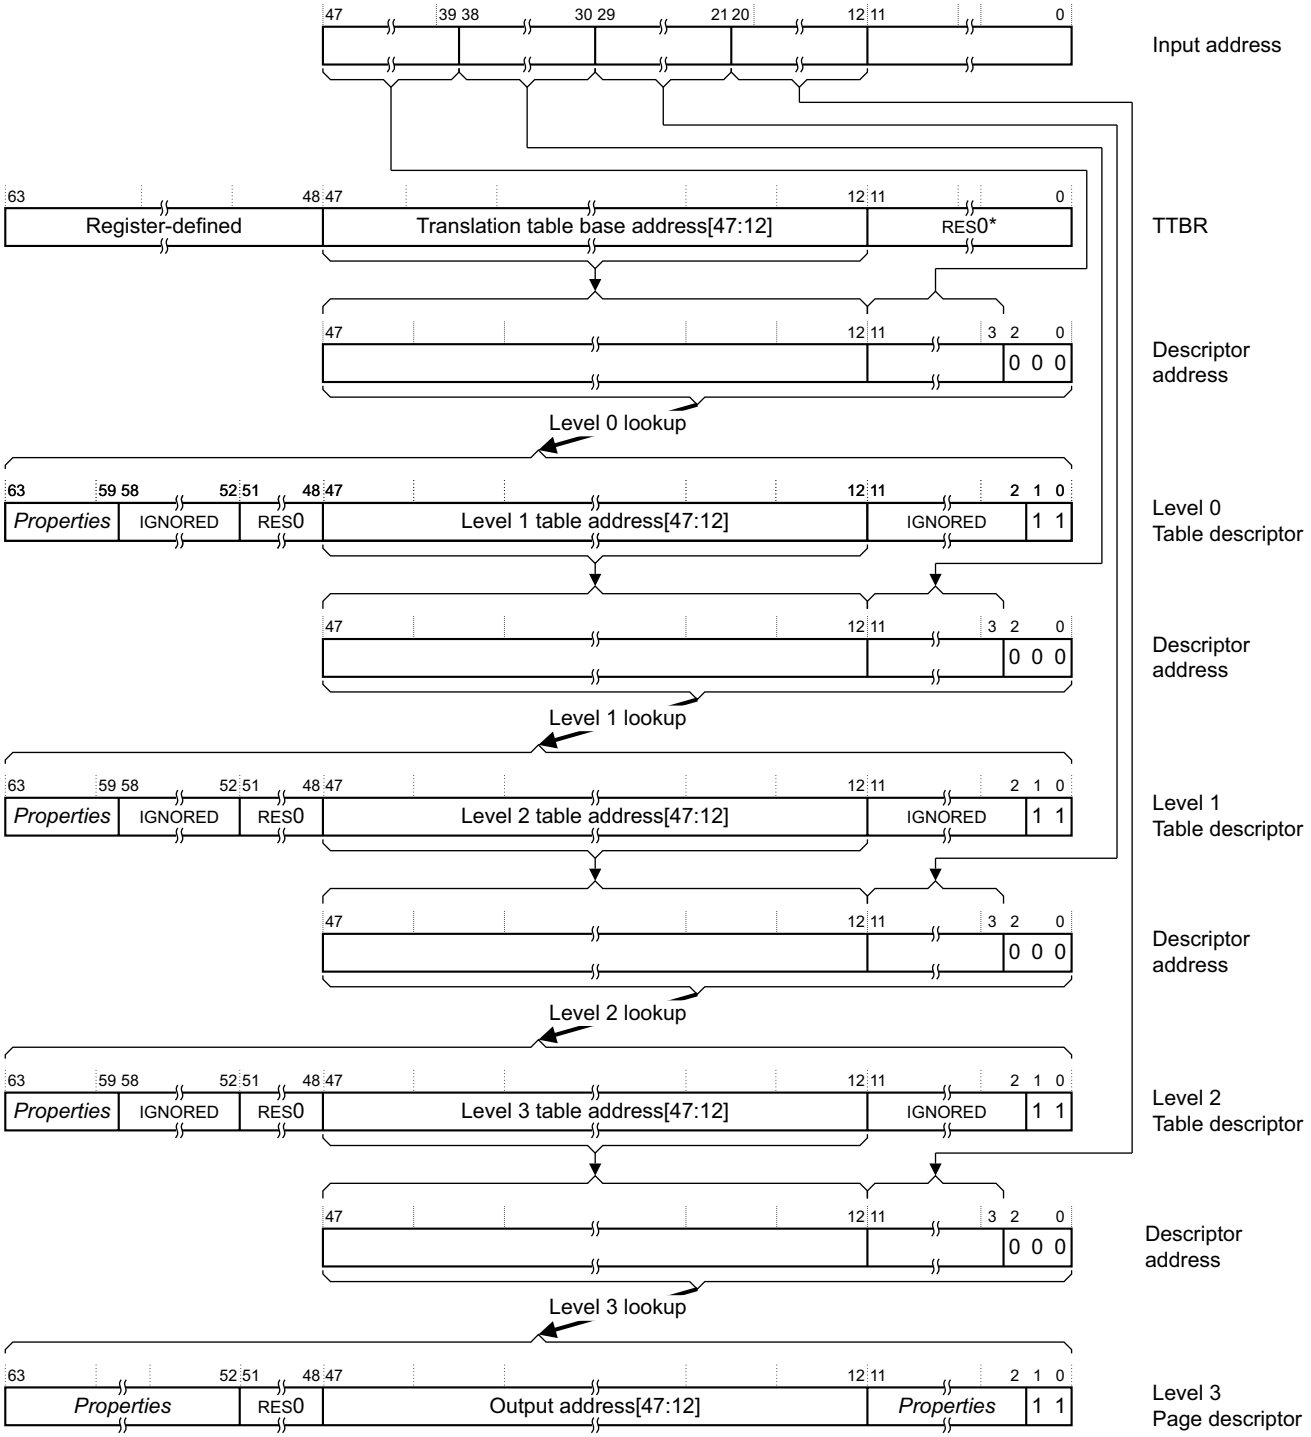
For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D5-2570.

Full translation flow using the 4KB granule and starting at level 0

Figure K7-10 on page K7-7706 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows*.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-10 Complete stage 1 translation of a 48-bit address using the 4KB translation granule

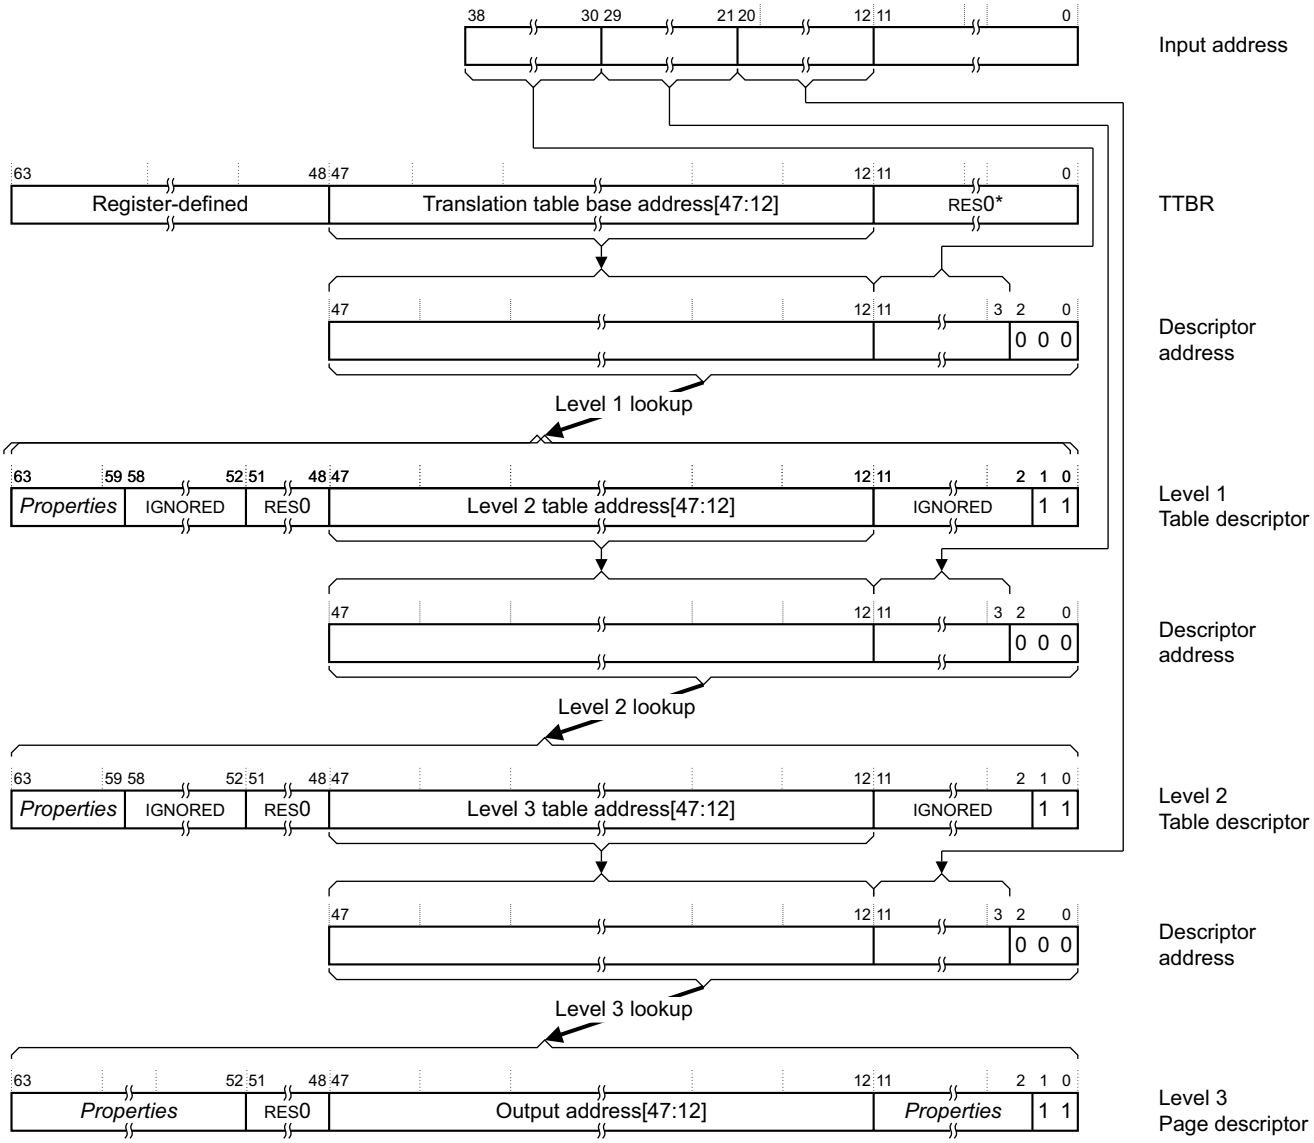
If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-10 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Full translation flow using the 4KB granule and starting at level 1

Figure K7-11 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-7705.



For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K7-11 Complete stage 1 translation of a 39-bit address using the 4KB translation granule

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-11 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-10 on page K7-7706, shows how the translation for the 42-bit address start the same lookup process one stage later.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Full translation flow using the 64KB granule and starting at level 1

Figure K7-10 on page K7-7706 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-7705.

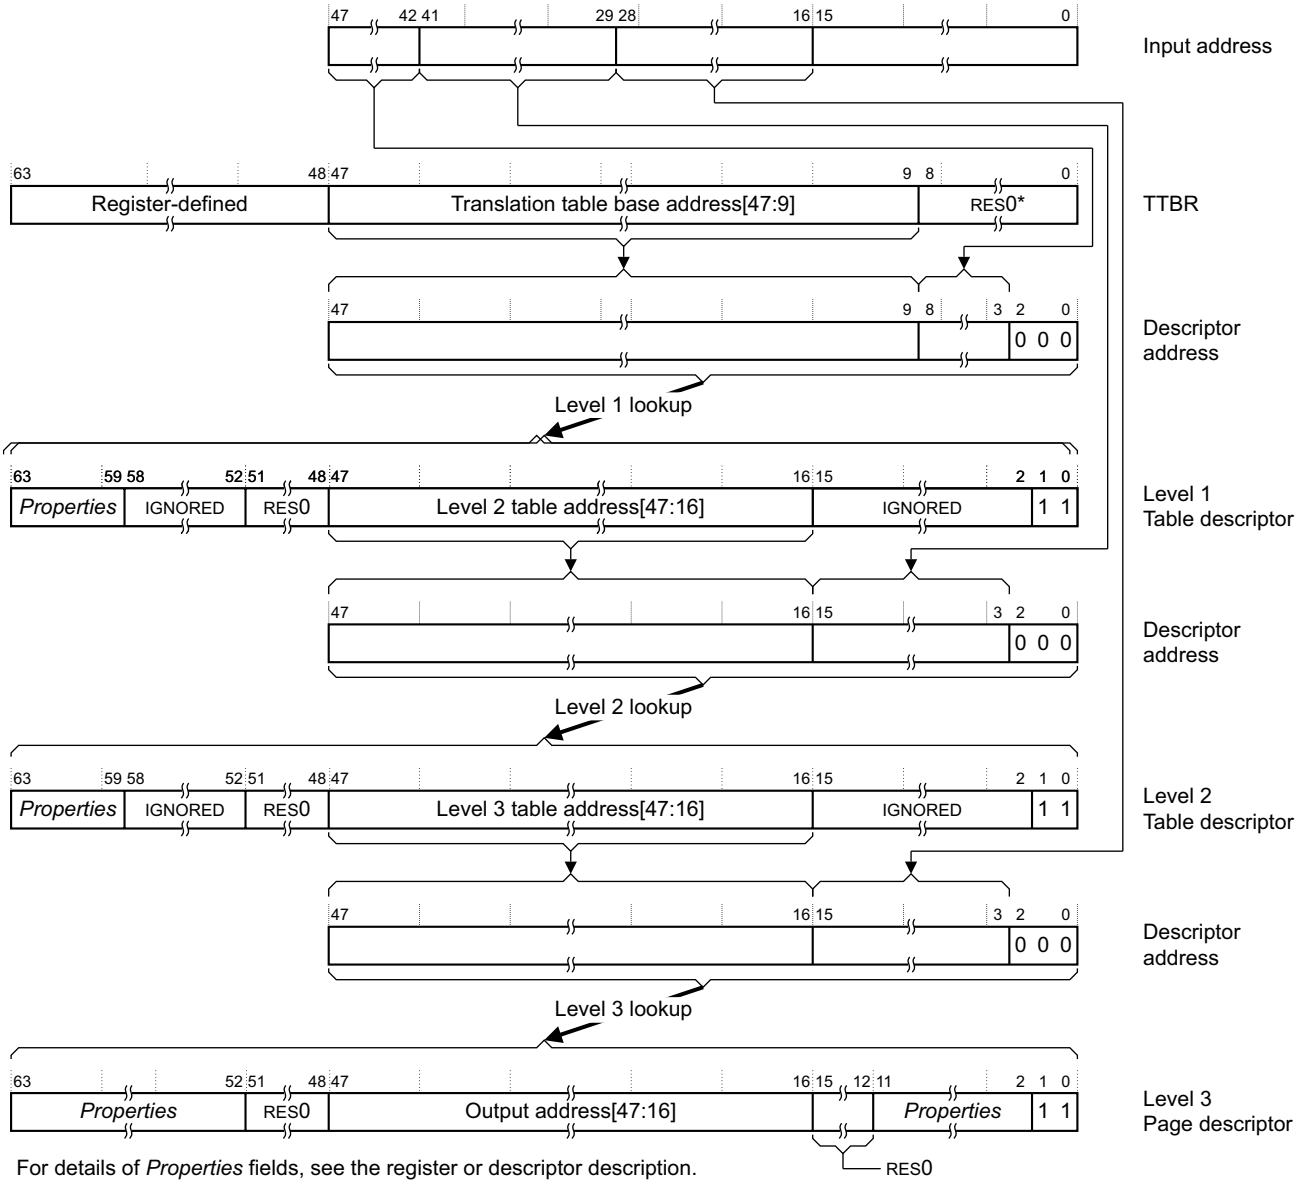


Figure K7-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

The level 1 lookup resolves only 6 bits of the input address. As described in *Performing the initial lookup using the 64KB translation granule* on page K7-7702, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the TTBR_ELx is extended, at the low-order end, to be bits[47:9].

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Full translation flow using the 64KB granule and starting at level 2

Figure K7-11 on page K7-7707 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K7-7705.

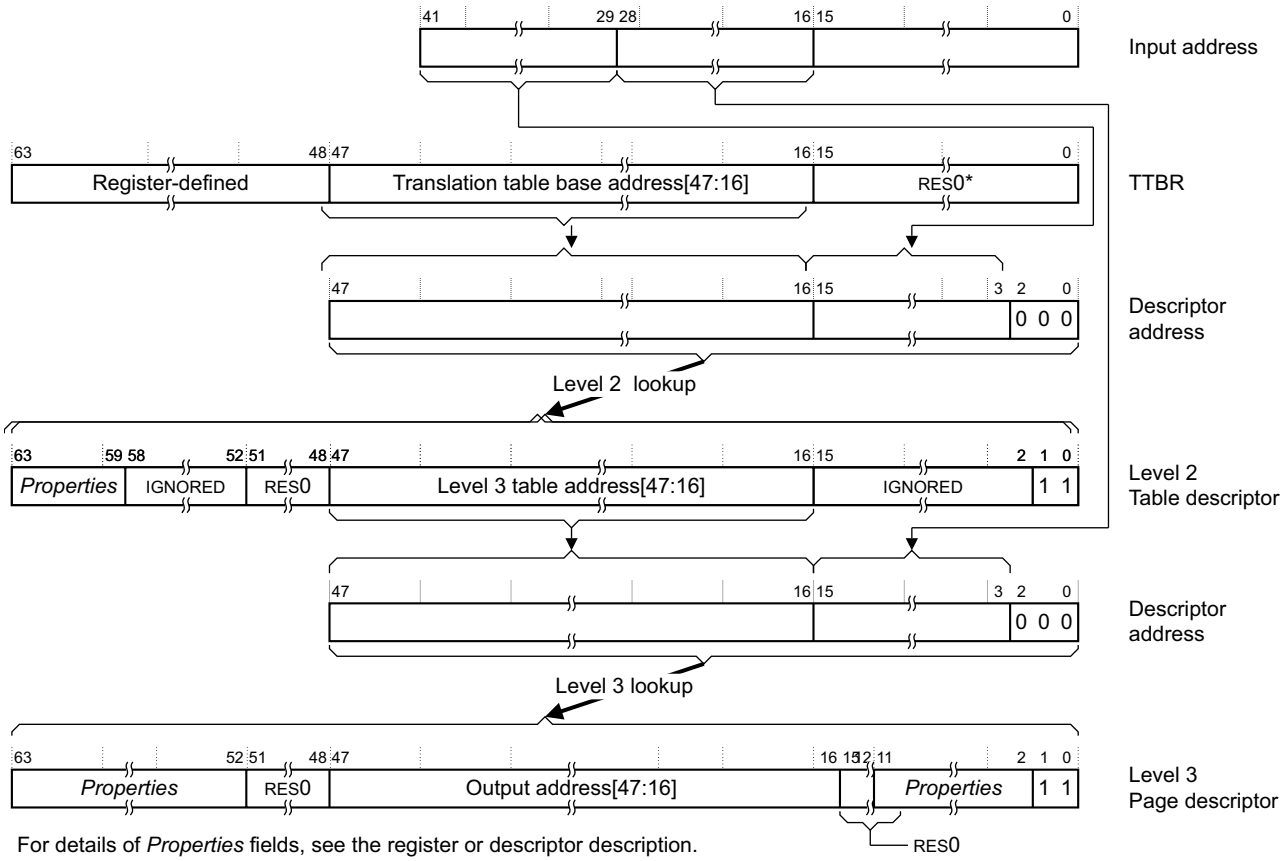

Figure K7-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K7-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K7-12 on page K7-7708, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the TTBR_ELx is bits[47:16].

K7.2 AArch32 Address translation examples

The following sections give address translation examples for the VMSAv8-32 address translation formats:

- *Address translation examples using the VMSAv8-32 Short descriptor translation table format*.
- *Address translation examples using the VMSAv8-32 Long descriptor translation table format* on page K7-7715.

K7.2.1 Address translation examples using the VMSAv8-32 Short descriptor translation table format

VMSAv8-32 Short-descriptor translation table format descriptors on page G5-5738 describes the memory section and page option for a single VMSAv8-32 address translation. The following sections show the full translation flow for each of these options:

- *Translation flow for a Supersection*.
- *Translation flow for a Section* on page K7-7711.
- *Translation flow for a Large page* on page K7-7712.
- *Translation flow for a Small page* on page K7-7713.

The address and Properties fields shown in the translation flows on page K7-7714 summarizes the information returned by the lookup.

Translation flow for a Supersection

Figure K7-14 on page K7-7711 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows* on page K7-7714.

‡ This field is absent if N is 0
L1 = Level 1, L2 = Level 2
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of *Properties* fields, see the register or descriptor description.

Figure K7-17 VMSAv8-32 Short-descriptor Small page address translation

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup* on page G5-5733, and the description of the register or translation table descriptor.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For translations using the Short-descriptor translation table format, *VMSAv8-32 Short-descriptor translation table format descriptors* on page G5-5738 describes the descriptors formats.

K7.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format

As described in *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G5-5761, in a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

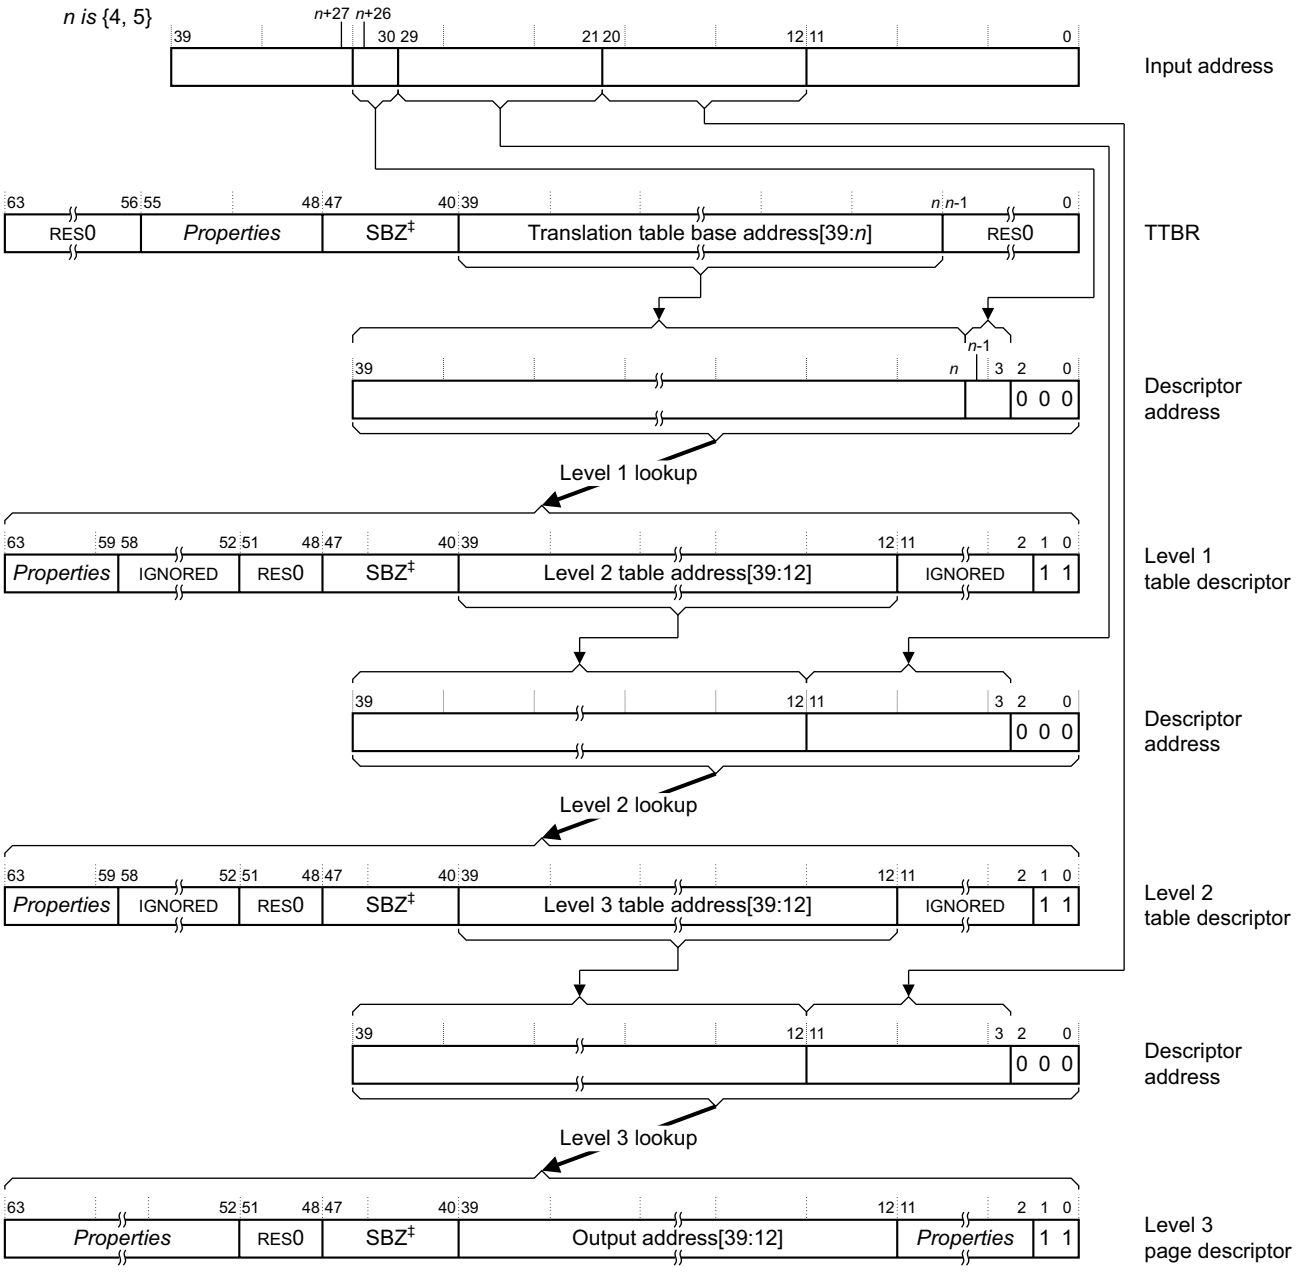
- *Full translation flow, starting at level 1 lookup*.
- *Full translation flow, starting at level 2 lookup* on page K7-7717.

The address and Properties fields shown in the translation flows on page K7-7714 summarizes the information returned by the lookup.

Full translation flow, starting at level 1 lookup

Figure K7-18 on page K7-7716 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K7-7714.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



For details of *Properties* fields, see the register or descriptor description.
‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

Figure K7-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see *Address size fault* on page G5-5812.

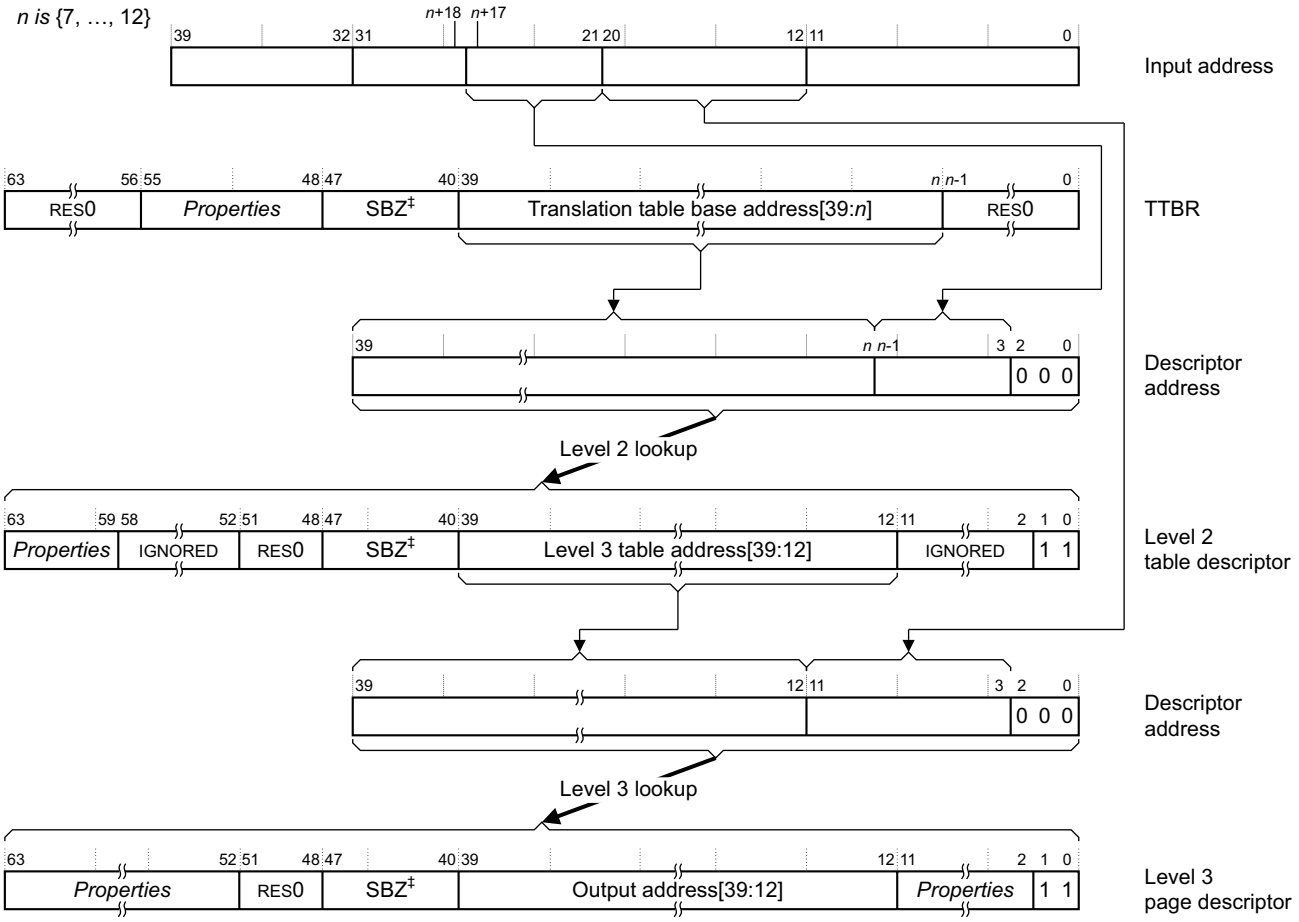
A stage 2 translation that starts at a level 1 lookup differs from the translation shown in Figure K7-18 only as follows:

- The possible values of *n* are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Full translation flow, starting at level 2 lookup

Figure K7-19 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K7-7714.



For details of *Properties* fields, see the register or descriptor description.
‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

Figure K7-19 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 2

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see *Address size fault* on page G5-5812.

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in Figure K7-19 only as follows:

- The possible values of *n* are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup* on page G5-5733, and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, *VMSAv8-32 Long-descriptor translation table format descriptors* on page G5-5747 describes the descriptors formats.

Appendix K9
Recommended Upload and Download Processes for External Debug

This appendix contains the following section:

- *Using memory access mode in AArch64 state* on page K9-7726.

Note

This description is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K9.1 Using memory access mode in AArch64 state

Figure K9-1 and Figure K9-2 on page K9-7727 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer *n* words of data:

- The download sequence needs *n*+6 accesses by the external debug interface.
- The upload sequence needs *n*+8 accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling EDSCR after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the EDSCR.ERR flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the EDSCR.ERR flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in X0. EDSCR.ERR might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

Note

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

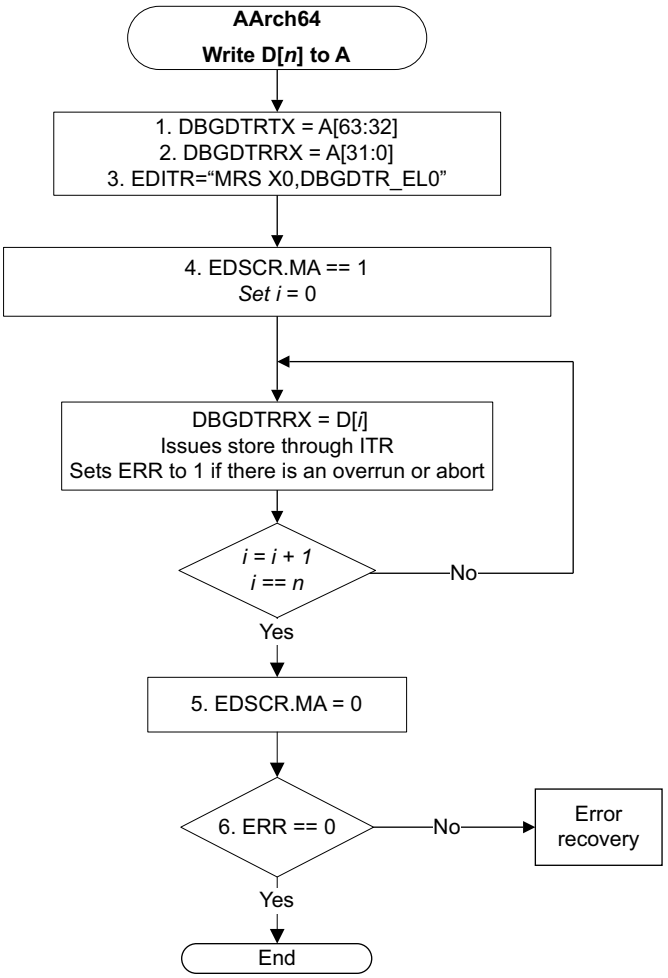

Figure K9-1 Fast code download in AArch64 state (external host to target)

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In Figure K9-1 on page K9-7726, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write `MRS X0, DBGDTR_EL0` to EDITR. The PE executes this instruction.
   d. Set EDSCR.MA to 1.
2. Loop *n* times. From the external debug interface:
   a. Write to DBGDTRRX_EL0. The PE reads the word from DTRRX and stores it to memory. It increments X0 by 4.
3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read EDSCR to check for overruns or Data Aborts during download.

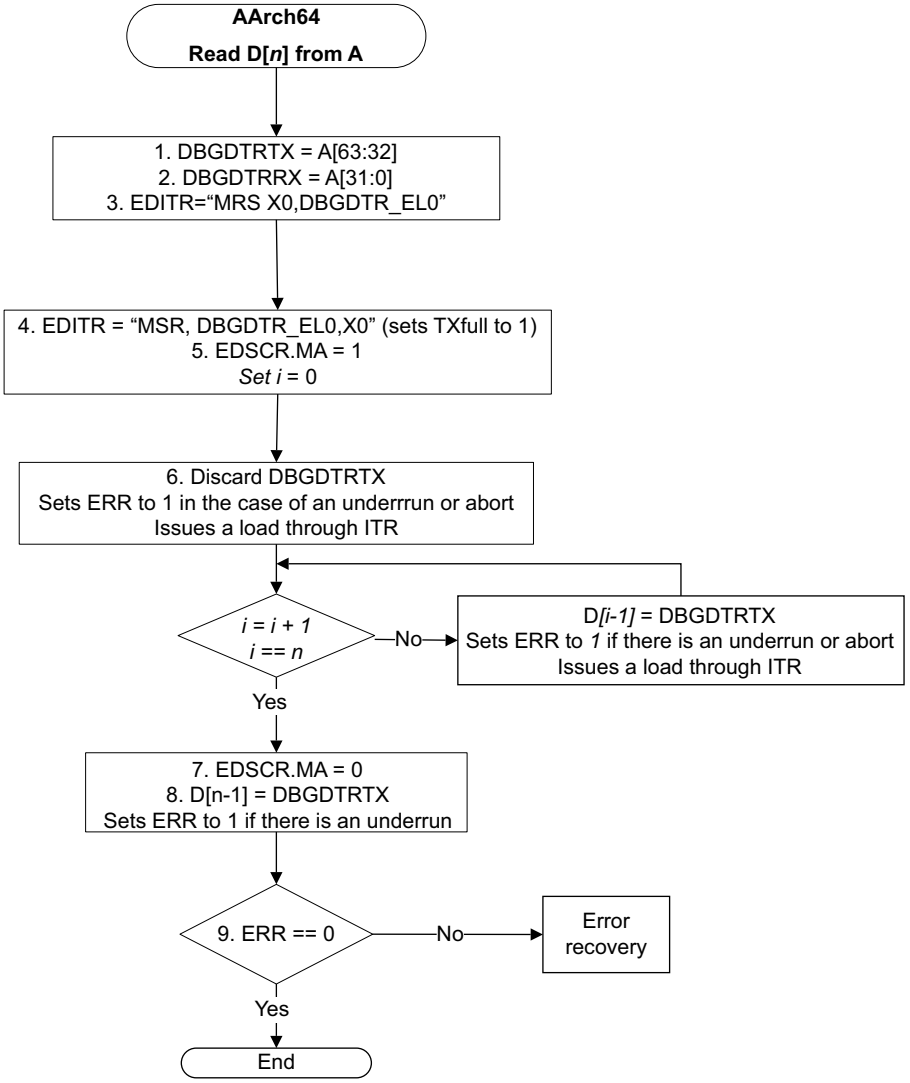

Figure K9-2 Fast data upload in AArch64 state (target to external host)

In Figure K9-2, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

b. Write address [63:32] to DBGDTRTX_EL0.

c. Write `MRS X0, DBGDTR_EL0` to EDITR.

d. Write `MSR DBGDTR_EL0, X0` to EDITR. This dummy operation ensures EDSCR.TXfull == 1.

e. Set EDSCR.MA to 1.

f. Read DBGDTRTX_EL0 and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments X0 by 4.

2. Loop *n*-1 times. From the external debug interface:

   a. Read DBGDTRTX_EL0. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments X0 by 4.

3. Epilogue. From the external debug interface:

   a. Clear EDSCR.MA to 0.

   b. Read DBGDTRTX_EL0 for the n^{th} value.

   c. Read EDSCR to check for underruns, overruns or Data Aborts during upload.

Appendix K10
Software Usage Examples

This appendix gives software usage examples, for cases where these are likely to contribute significantly to an understanding of the Arm architecture.

It contains the following sections:

- *Use of the Advanced SIMD complex number instructions* on page K10-7730.
- *Use of the Armv8.2 extensions to the Cryptographic Extension* on page K10-7732.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K10.1 Use of the Advanced SIMD complex number instructions

ARMv8.3-CompNum provides instructions to aid floating-point computations of complex numbers. This section illustrates the use of these instructions for complex arithmetic. It is not part of the Arm architecture definition.

This section uses the AArch64 instructions `FCADD` and `FCMLA` - usage of the AArch32 instructions `VCADD` and `VCMLA` is similar.

When using the instructions implemented by ARMv8.3-CompNum, a complex numbers is represented in a SIMD&FP register as a pair of adjacent elements, each holding a floating-point number, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number.

K10.1.1 Complex addition

Simple complex addition on a vector of complex numbers is already provided by the vector form of the `FADD` instruction.

The functionality that `FCADD` adds is to rotate each complex number in the second vector by 90 degrees or 270 degrees counterclockwise (considering the complex numbers on an Argand diagram) before performing the addition. Mathematically, this is equivalent to multiplying the second complex number by i or -i before addition.

This means, given a complex number z stored in a pair of elements in one vector, and a complex number w stored in the corresponding element pair in another vector:

- `FADD` calculates z + w.
- `FCADD` calculates z ± iw.

K10.1.2 Complex multiplication

The `FCMLA` instruction does not provide functionality for complex multiplication directly. However, a pair of `FCMLA` instructions can provide this function.

The `FCMLA` instruction operates on corresponding pairs of complex numbers stored in SIMD&FP vector registers, and adds the result to the corresponding complex number in the destination SIMD&FP vector register. This computation is as follows:

1. The second complex number is rotated by 0, 90, 180 or 270 degrees counterclockwise.
2. That complex number is multiplied by either the real or imaginary part of the first complex number:
   - When the rotation is 0 or 180 degrees, the real part is used.
   - When the rotation is 90 or 270 degrees, the imaginary part is used.
3. The resulting complex number is added to the corresponding complex number in the destination register.

Mathematically, considering the complex numbers on an Argand diagram:

- Rotation by 180 degrees is equivalent to negation.
- Rotation by 90 degrees is equivalent to multiplying by i.
- Rotation by 270 degrees is equivalent to multiplying by -i.

This means that, for a first complex number z, where z = a+bi, and a second complex number w, if initially the corresponding complex number in the destination register is zero:

- When the rotation is 0 degrees the result of the multiply-add is aw.
- When the rotation is 180 degrees, the result is -aw.
- When the rotation is 90 degrees, the result is biw.
- When the rotation is 270 degrees, the result is -biw.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This means that, if the destination register is zeroed and an FCMLA instruction is executed with a rotation parameter of 0, and then the same instruction is executed with a rotation parameter of 90:

- The first execution returns aw in the destination register.
- The second execution accumulates biw to this, meaning the result is aw+biw.
- This result is the product of (a+bi)w, which is the product zw.

So, this pair of instructions can be used to implement complex multiplication.

After zeroing V0, the syntax of a pair of instructions to perform this complex number multiplication might be:

```
FCMLA V0.4S, V1.4S, V2.4S, #0
FCMLA V0.4S, V1.4S, V2.4S, #90
```

Other simple pairs of FCMLA instructions perform useful computations. For example, considering a first complex number z and second complex number w, defined as before, and a destination register that has been zeroed before the first FCMLA instruction is executed:

1. The following pair of instructions calculates the complex conjugate of z multiplied by w.

   ```
   FCMLA V0.4S, V1.4S, V2.4S, #0
   FCMLA V0.4S, V1.4S, V2.4S, #270
   ```

2. The following pair of instructions calculates the negation of z multiplied by w.

   ```
   FCMLA V0.4S, V1.4S, V2.4S, #180
   FCMLA V0.4S, V1.4S, V2.4S, #270
   ```

3. The following pair of instructions calculates the negation of the complex conjugate of z multiplied by w.

   ```
   FCMLA V0.4S, V1.4S, V2.4S, #180
   FCMLA V0.4S, V1.4S, V2.4S, #90
   ```

Note

For these examples, the following caveats must be considered:

- FCMLA performs a fused multiply-add, meaning there is no intermediate rounding. This lack of intermediate rounding can give unexpected results in some cases. Arm expects that these instructions are only used in situations where the effect of the rounding of these results is not material to the calculation.
- When using the FCMLA instructions, the behavior of (∞+∞i) multiplied by (0+i) is (NaN+NaNi), rather than the result expected by ISO C, which is complex ∞.

K10.2 Use of the Armv8.2 extensions to the Cryptographic Extension

K10.2.1 Use of the SHA512 instructions

These instructions are implemented when ARMv8.2-SHA is implemented.

The following code sequence shows the use of the SHA512 instructions to calculate a SHA512 hash iteration of 80 rounds. This code is not fully optimized.

```
// X0 contains the pointer to the bottom of the (padded) 16*64 bytes of message to be
// hashed, with space above the that message to hold a further 64 * 64 bytes of working
// data
// X1 contains the pointer to the 0th element of 80 64-bit constants (in ascending addresses) defined in
the SHA2 specification
// X2 contains a loop variable
// V4,V5,V6, V7 hold VS0 to VS3 respectively
// V8 holds running hash V1
// V9 holds running hash V0
    MOV        X2, #0
loop1:
  LD1        {V0.2D}, [X0]                 // Data
  LD1        {V1.2D}, [X1]                 // K values
  ADD        X1, X1, #16
  ADD        X0, X0, #16
  ADD        X2, X2, #16
  ADD        V2.2D, V0.2D, V1.2D
  EXT        V2.16B, V2.16B, V2.16B, #8

K10.2.2 Use of the SHA3 instructions

These instructions are implemented when ARMv8.2-SHA is implemented.

The following code sequence shows the use of the SHA3 instructions to obtain the combined theta, phi, rho and chi operations of a SHA3 iteration. Arm expects the iota operation to be performed using a lookup table.

This code is not fully optimized for multiple iterations.

```
// Input State:
    //      x=0   x=1   x=2   x=3   x=4
    // y=0  v12   v13   v14   v10   v11
    // y=1   v7    v8    v9    v5    v6
    // y=2   v2    v3    v4    v0    v1
    // y=3  v22   v23   v24   v20   v21
    // y=4  v17  v18    v19   v15   v16

Appendix K11
Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the Armv8 architecture. It contains the following sections:

- *Introduction* on page K11-7740.
- *Load-Acquire, Store-Release and barriers* on page K11-7743.
- *Load-Acquire Exclusive, Store-Release Exclusive and barriers* on page K11-7747.
- *Using a mailbox to send an interrupt* on page K11-7752.
- *Cache and TLB maintenance instructions and barriers* on page K11-7753.
- *Armv7 compatible approaches for ordering, using DMB and DSB barriers* on page K11-7765.

Note

This information is not part of the Arm architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

K11.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the Armv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

K11.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the *Sequential Execution Model* (SEM), and in this Manual it is described as *Simple sequential execution* of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as Arm, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the Arm architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the `ISB` instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of *memory consistency*. Processor architectures have adopted one or more *memory consistency models*, or *memory models*, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and Arm recommends the *Memory Consistency Models for Shared Memory-Multiprocessors* paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the Arm architecture from Armv6. In particular, the examples show how the use of the `DMB` and `DSB` memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

K11.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

DMB See *Data Memory Barrier (DMB)* on page B2-125.

DSB See *Data Synchronization Barrier (DSB)* on page B2-128.

ISB See *Instruction Synchronization Barrier (ISB)* on page B2-125.

Observer, Completion

See *Definition of the Armv8 memory model* on page B2-115.

See *Completion and endpoint ordering* on page B2-120.

Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

K11.1.3 Conventions

Many of the examples are written in a stylized extension to Arm assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
    LDR R12, [Rx]
    CMP R12, #1
    BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
   loop
    LDA R12, [Rx]       ; load acquire ensures it is ordered before subsequent loads/stores
    CMP R12, #1
    BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
    LDR W12, [Xx]
    CMP W12, #1
    B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` and describes the following sequence:

```
   loop
    LDAR W12, [Xx]       ; load acquire ensures it is ordered before subsequent loads/stores
    CMP W12, #1
    B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1…P*x* refer to caching coherent PEs that implement the Armv8 architecture, and are in the same shareability domain.
- E0, E1…E*x* refer to non-caching observers, that do not participate in the coherency protocol, but execute Armv8 instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

Note

Throughout this appendix, *Armv8 instruction* and *instruction* refer to instructions from the A64, A32, or T32 instruction set, provided by Armv8 implementations.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Results are expressed in terms of `<agent>:<register>`, such as `P0:R5`. The results can be described as:

Permissible This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

Not permissible Results that the architecture expressly forbids.

Required Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of `DMB` and `DSB` instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a `DMB ST`, that is a barrier to stores only, this is shown by the use of `DMB [ST]`. This indicates that the `ST` qualifier can be omitted without affecting the result of the test. In some implementations `DMB ST` is faster than `DMB`.

For AArch64 code, the shareability domain of the `DMB` or `DSB` must be included. This is shown in this manual using the notation `DMB <domain>` and `DSB <domain>` respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
  - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
  - The address held in R3 is in Write-Through Cacheable Normal memory.
  - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
  - When used with an `STR` instruction, `0x55`, `0x66`, `0x77`, and `0x88` respectively.
  - When used with an `LDR` instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- *Cache maintenance system instructions* on page K14-7861.
- *TLB maintenance system instructions* on page K14-7862.

K11.2 Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-129.

The following sections show that most of the examples in sections *Simple ordering and barrier cases* on page K11-7765 and *Load-Exclusive, Store-Exclusive and barriers* on page K11-7769 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

K11.2.1 Message passing

The following sections describe:

- *Resolving weakly-ordered message passing by using Acquire and Release*.
- *Resolving message passing by the use of Store-Release and address dependency* on page K11-7744.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in *Weakly-ordered message passing problem* on page K11-7765 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

AArch32

P1

```
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P3

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

Non-Confidential

Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in *Message passing with multiple observers* on page K11-7766 can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

AArch32

P1

```
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                      : and so is ordered after the flag has been seen
```

AArch64

P1

```
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([X2]==1)
AND W12, W12, WZR     ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                      : and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of `0x55`.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]     ; the load has an address dependency on R12
                      : and so is ordered after the flag has been seen
```

AArch64

P3

```
WAIT([X2]==1)
AND W12, W12, WZR     ; R12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]     ; the load has an address dependency on W12
                      : and so is ordered after the flag has been seen
```

K11.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

AArch32

P1

```
STR R5, [R1, #offset] ; sets new data in a field
STL R1, [R2]          ; updates base address
```

P2

```
LDR R1, [R2]          ; reads base address
CMP R1, #0            ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

AArch64

P1

```
STR W5, [X1, #offset] ; sets new data in a field
STLR X1, [X2]         ; updates base address
```

P2

```
LDR X1, [X2]          ; reads base address
CMP X1, #0            ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.

Non-Confidential

K11.2.3 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit `DSB` barrier instruction is required if it is necessary to ensure memory accesses made before the `WFI` or `WFE` are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the `DMB` described in *Posting a store before polling for acknowledgement* on page K11-7768, or a dependency on a load.

The following example requires the `DSB` to ensure that the store is visible:

AArch32

P1

```
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

AArch64

P1

```
    STR W0, [X2]
    DSB <domain>
Loop
    WFI
    B Loop
```

This requirement is unchanged in Armv8 by the presence of Load-Acquire or Store-Release.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K11.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The Armv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using `LDREX` and `STREX`).
- Acquire only semantics (using `LDAEX` and `STREX`).
- Release only semantics (using `LDREX` and `STLEX`).
- Sequentially consistent semantics (using `LDAEX` and `STLEX`).

In addition, the Armv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of `WFE`, by removing the need for a `DSB` barrier and `SEV` instruction.

K11.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

Note

The inclusion of AArch32 `PLDW` instructions or AArch64 `PFRM PST*` instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

Px

```
    PLDW[R1]              ; preload into cache in unique state
Loop
    LDAEX R5, [R1]        ; read lock with acquire
    CMP R5, #0            ; check if 0
    STREXEQ R5, R0, [R1]  ; attempt to store new value
    CMPEQ R5, #0          ; test if store suceeded
    BNE Loop              ; retry if not

    ; loads and stores in the critical region can now be performed
```

AArch64

Px

```
    PRFM PSTL1KEEP, [X1]  ; preload into cache in unique state
Loop
    LDAXR W5, [X1]        ; read lock with acquire
    CBNZ W5, Loop         ; check if 0
    STXR W5, W0, [X1]     ; attempt to store new value
    CBNZ W5, Loop         ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K11.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

AArch32

Px

```
    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]          ; clear the lock with release semantics
```

AArch64

Px

```
    ; loads and stores in the critical region
    STLR WZR, [X1]        ; clear the lock with release semantics
```

K11.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

Note

- The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.
- The inclusion of AArch32 `PLDW` instructions or AArch64 `PFRM PST*` instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

This is shown in the implementation below:

AArch32

Px

```
    ; R1 holds two 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]              ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]        ; read current and next
    ADD R5, R5, #0x10000  ; increment the next number
    STREX R6, R5, [R1]    ; and update the value
    CMP R6, #0            ; did the exclusive pass
    BNE Loop1             ; retry if not
    CMP R5, R5, ROR #16   ; is the current ticket ours
    BEQ block_start
Loop2
    LDAH R6, [R1]         ; read current value
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    CMP R6, R5, LSR #16   ; compare it with our allocated ticket
    BNE Loop2             ; retry (spin) if it is not the same
block_start
```

AArch64

Px

```
    ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PRFM PSTL1KEEP, [X1]  ; preload into cache in unique state
Loop1
    LDAXR W5, [X1]        ; read current and next
    ADD W5, W5, #0x10000  ; increment the next number
    STXR W6, W5, [X1]     ; and update the value
    CBNZ W6, Loop1        ; did the exclusive pass - retry if not

    AND W6, W5, #0xFFFF
    CMP W6, W5, LSR #16   ; is the current ticket ours
    B.EQ block_start
Loop2
    LDARH W6, [X1]        ; read current value
    CMP W6, W5, LSR #16   ; compare it with the our allocated ticket
    B.NE Loop2            ; retry (spin) if it isn't the same
block_start
```

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

AArch32

```
    ADD R6, R6, #1
    STLH R6, [R1]
```

AArch64

```
    ADD W6, W6, #1
    STLRH W6, [X1]
```

K11.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The Armv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In Armv8, the event can be generated as a result of clearing the global monitor, so removing the need for a `DSB` barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

Note

The inclusion of AArch32 `PLDW` instructions or AArch64 `PFRM PST*` instructions in these examples is not a functional requirement, but will improve performance on many implementations. The performance benefit of adding these instructions will vary between different implementations of the architecture.

Simple lock

The following is an example of lock acquire code using `WFE`:

AArch32

Px

Non-Confidential

```
    PLDW[R1]              ; preload into cache in unique state
Loop
    LDAEX R5, [R1]        ; read lock with acquire
    CMP R5, #0            ; check if 0
    WFENE                 ; sleep if the lock is held
    STREXEQ R5, R0, [R1]  ; attempt to store new value
    CMPEQ R5, #0          ; test if store succeeded
    BNE Loop              ; retry if not
```

AArch64

Px

```
    SEVL                  ; invalidates the WFE on the first loop iteration
    PRFM PSTL1KEEP, [X1]  ; allocate into cache in unique state
Loop
    WFE
    LDAXR W5, [X1]        ; read lock with acquire
    CBNZ W5, Loop         ; check if 0
    STXR W5, W0, [X1]     ; attempt to store new value
    CBNZ W5, Loop         ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code:

AArch32

Px

```
    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]          ; clear the lock
```

AArch64

Px

```
    ; loads and stores in the critical region
    STLR WZR, [X1]        ; clear the lock
```

Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for the express purpose of creating an event when the monitor changes state:

AArch32

Px

```
    ; R1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]              ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]        ; read current and next
    ADD R5, R5, #0x10000  ; increment the next number
    STREX R6, R5, [R1]    ; and update the value
    CMP R6, #0            ; did the exclusive pass
    BNE Loop              ; retry if not
    CMP R5, R5, ROR #16   ; is the current ticket ours
    BEQ block_start
    SEVL
Loop2
    WFE                   ; wait if there has not been a change to the count since last
```

K11.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a `DSB` instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

AArch32

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```

K11.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- *Data cache maintenance instructions*.
- *Instruction cache maintenance instructions* on page K11-7757.
- *TLB maintenance instructions and barriers* on page K11-7760.

K11.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- *Message passing to non-caching observers*.
- *Multiprocessing message passing to non-caching observers*.
- *Invalidating DMA buffers, non-functional example* on page K11-7754.
- *Invalidating DMA buffers, functional example with single PE* on page K11-7755.
- *Invalidating DMA buffers, functional example with multiple coherent PEs* on page K11-7756.

Message passing to non-caching observers

The Armv8 architecture requires the use of `DMB` instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

AArch32

P1

```
STR R5, [R1]          ; updates data (assumed to be in P1 cache)
DCCMVAC R1            ; cleans cache to point of coherency
DMB                   ; ensures effects of the clean will be observed before the
                      ; flag is set
STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([R4] == 1)  ; waits for the flag (with order)
LDR R5, [R1]          ; reads the data
```

AArch64

P1

```
STR W5, [X1]          ; updates data (assumed to be in P1 cache)
DC CVAC, X1           ; cleans cache to point of coherency
DMB ISH               ; ensures effects of the clean will be observed before the
                      ; flag is set
STR W0, [X4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([X4] == 1)  ; waits for the flag (with order)
LDR W5, [X1]          ; reads the data
```

In this example, it is required that E1:R5==`0x55`.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

AArch32

P1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    STR R5, [R1]          ; updates data (assumed to be in P1 cache)
    STL R0, [R2]          ; sends a flag for P2 (ordered by the store release)
```

P2

```
    WAIT ([R2] == 1)      ; waits for P1 flag
    DMB                   ; ensures cache clean is observed after P1 flag is observed
    DCCMVAC R1            ; cleans cache to point of coherency - will clean P1 cache
    DMB                   ; ensures effects of the clean will be observed before the
                          ; flag to E1 is set
    STR R0, [R4]          ; sends flag to E1
```

E1

```
    WAIT_ACQ ([R4] == 1)  ; waits for P2 flag (ordered)
    LDR R5, [R1]          ; reads data
```

AArch64

P1

```
    STR W5, [X1]          ; updates data (assumed to be in P1 cache)
    STLR W0, [X2]         ; sends a flag for P2 (ordered)
```

P2

```
    WAIT ([X2] == 1)      ; waits sfor P1 flag
    DMB SY                ; ensure cache clean is observed after P1 flag is observed
    DC CVAC, X1           ; cleans cache to point of coherency, will clean P1 cache
    DMB SY                ; ensures effects of the clean will be observed before the
                          ; flag to E1 is set
    STR W0, [X4]          ; sends flag to E1
```

E1

```
    WAIT_ACQ ([X4] == 1)  ; waits for P2 flag
    LDR W5, [X1]          ; reads data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Note

The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

AArch32

P1

```
    DCIMVAC R1            ; ensures cache is not dirty. A clean operation could be used
                          ; but as the DMA will subsequently overwrite this region an
                          ; invalidate operation is sufficient and usually more efficient
    DMB                   ; ensures cache invalidation is observed before the next store
                          ; is observed
    STR R0, [R3]          ; sends flag to external agent
    WAIT_ACQ ([R4]==1)    ; waits for a different flag from an external agent
    LDR R5, [R1]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E1

```
WAIT ([R3] == 1)      ; waits for flag
STR R5, [R1]          ; stores new data
STL R0, [R4]          ; sends a flag
```

AArch64

P1

```
DC IVAC, X1           ; ensure cache is not dirty. A clean operation could be used
                      ; but as the DMA will subsequently overwrite this region an
                      ; invalidate operation is sufficient and usually more efficient
DMB SY                ; ensures cache invalidation is observed before the next store
                      ; is observed
STR W0, [X3]          ; sends flag to external agent
WAIT_ACQ ([X4]==1)    ; waits for a different flag from an external agent
LDR W5, [X1]
```

E1

```
WAIT ([X3] == 1)      ; waits for flag
STR W5, [X1]          ; stores new data
STLR W0, [X4]         ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

AArch32

P1

```
DCIMVAC R1            ; ensures cache is not dirty. A clean operation could be used
                      ; but as the DMA will subsequently overwrite this region an
                      ; invalidate operation is sufficient and usually more efficient
DMB                   ; ensures cache invalidation is observed before the next store
                      ; is observed
STR R0, [R3]          ; sends flag to external agent
WAIT ([R4]==1)        ; waits for a different flag from an external agent
DMB                   ; ensures that cache invalidate is observed after the flag
                      ; from external agent is observed
DCIMVAC R1            ; ensures cache discards stale copies before use
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)      ; waits for flag
STR R5, [R1]          ; stores new data
STL R0, [R4]          ; sends a flag
```

AArch64

P1

```
DC IVAC, X1           ; ensures cache is not dirty. A clean operation could be used
                      ; but as the DMA will subsequently overwrite this region an
                      ; invalidate operation is sufficient and usually more efficient
DMB SY                ; ensures cache invalidation is observed before the next store
                      ; is observed
STR W0, [X3]          ; sends flag to external agent
WAIT ([X4]==1)        ; waits for a different flag from an external agent
DMB SY                ; ensures that cache invalidate is observed after the flag
                      ; from external agent is observed
DC IVAC, X1           ; ensures cache discards stale copies before use
LDR W5, [X1]
```

E1

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
WAIT ([X3] == 1)      ; waits for flag
STR W5, [X1]          ; stores new data
STLR W0, [X4]         ; sends a flag
```

In this example, the result P1:R5 == `0x55` is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of `DMB` instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

AArch32

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
STL R0, [R2]          ; signals release of [R1]
WAIT_ACQ ([R2] == 0)  ; waits for new value from DMA
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1)      ; waits for release of [R1] by P0
DCIMVAC R1            ; ensures caches are not dirty, an invalidate is sufficient
DMB
STR R0, [R3]          ; requests new data for [R1]
WAIT ([R4] == 1)      ; waits for new data
DMB
DCIMVAC R1            ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]          ; signals availability of new [R1]
```

E1

```
WAIT ([R3] == 1)      ; waits for new data request
STR R5, [R1]          ; sends new [R1]
DMB [ST]
STR R0, [R4]          ; indicates that new data is available to P1
```

AArch64

P0

```
(Use data from [X1], potentially using [X1] as scratch space)
STLR W0, [X2]         ; signals release of [X1]
WAIT_ACQ ([X2] == 0)  ; waits for new value from DMA
LDR W5, [X1]
```

P1

```
WAIT ([X2] == 1)      ; waits for release of [R1] by P0
DC IVAC, X1           ; ensures caches are not dirty, an invalidate is sufficient
DMB SY
STR W0, [X3]          ; requests new data for [R1]
WAIT ([X4] == 1)      ; waits for new data
DMB SY
DCIMVAC X1            ; ensures caches discard stale copies before use
DMB SY
STR WZR, [X2]         ; signals availability of new [R1]
```

E1

```
WAIT ([X3] == 1)      ; waits for new data request
STR W5, [X1]          ; sends new [R1]
STR W0, [X4]          ; indicates new data is available to P1
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

K11.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- *Ensuring the visibility of updates to instructions for a uniprocessor*.
- *Ensuring the visibility of updates to instructions for a multiprocessor*.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

AArch32

P1

```
STR R11, [R1]         ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1            ; clean to PoU makes the new instruction visible to the instruction cache
DSB
ICIMVAU R1            ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1
DSB                   ; ensures completion of the invalidation
ISB                   ; ensures instruction fetch path sees new instruction cache state
BX R1
```

In AArch64 state, the branch predictor maintenance is not required.

AArch64

P1

```
STR W11, [X1]         ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1           ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH
IC IVAU, X1           ; ensures instruction cache/branch predictor discards stale data
DSB ISH               ; ensures completion of the invalidation
ISB                   ; ensures instruction fetch path sees new instruction cache state
BR X1
```

Note

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

Ensuring the visibility of updates to instructions for a multiprocessor

The Armv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AArch32

P1

```
STR R11, [R1]          ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1             ; clean to PoU makes the new instruction visible to the instruction cache
DSB                    ; ensures completion of the clean on all PEs
ICIMVAU R1             ; ensures instruction cache discards stale data
BPIMVA R               ; ensures branch predictor discards stale data
DSB                    ; ensures completion of the instruction cache and branch predictor
                       ; invalidation on all PEs
STR R0, [R2]           ; sets flag to signal completion
ISB                    ; synchronizes context on this PE
BX R1                  ; branches to new code
```

P2-P*x*

```
WAIT ([R2] == 1)       ; waits for flag signalling completion
ISB                    ; synchronizes context on this PE
BX R1                  ; branches to new code
```

AArch64

P1

```
STR X11, [X1]          ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1            ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH                ; ensures completion of the clean on all PEs
IC IVAU, X1            ; ensures instruction cache/branch predictor discards stale data
DSB ISH                ; ensures completion of the instruction cache/branch predictor
                       ; invalidation on all PEs
STR W0, [X2]           ; sets flag to signal completion
ISB                    ; synchronizes context on this PE
BR R1                  ; branches to new code
```

P2-P*x*

```
WAIT ([X2] == 1)       ; waits for flag signalling completion
ISB                    ; synchronizes context on this PE
BR X1                  ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

AArch32

P1

```
STR R11, [R1]          ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1             ; clean to PoU makes the new instruction visible to the instruction cache
DSB                    ; ensures completion of the clean on all PEs
ICIMVAU R1             ; ensures instruction cache discards stale data
BPIMVA R1              : ensures branch predictor discards stale data
DMB                    ; ensures ordering of the store after the invalidation
                       ; DOES NOT guarantee completion of instruction cache/branch
                       ; predictor on other PEs
STR R0, [R2]           ; sets flag to signal completion
DSB                    ; ensures completion of the invalidation on all PEs
ISB                    ; synchronizes context on this PE
BX R1                  ; branches to new code
```

P2-P*x*

```
WAIT ([R2] == 1)       ; waits for flag signalling completion
DSB                    ; this DSB does not guarantee completion of P1
                       ; ICIMVAU/BPIMVA
ISB
BX R1
```

K11.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- *Ensuring the visibility of updates to translation tables for a uniprocessor*.
- *Ensuring the visibility of updates to translation tables for a multiprocessor*.
- *Paging memory in and out* on page K11-7761.
- *Using break-before-make when updating translation table entries* on page K11-7762.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

The Armv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a `DSB` and an `ISB`. Therefore, the code for updating a translation table entry is:

AArch32

P1

```
STR R11, [R1]         ; updates the translation table entry
DSB                   ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                   ; ensures completion of the BP and TLB invalidation
ISB                   ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]         ; updates the translation table entry
DSB ISH               ; ensures visibility of the update to translation table walks
TLBI VAE1, X10        ; assumes we are in the EL1
DSB ISH               ; ensures completion of the TLB invalidation
ISB                   ; synchronise context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The Armv8 architecture requires a PE that executes a TLB maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a `DSB` that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

Non-Confidential

AArch32

P1

```
STR R11, [R1]         ; updates the translation table entry
DSB                   ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                   ; ensures completion of the BP and TLB invalidation
ISB                   ; Note ISB is not broadcast and must be executed locally
                      ; on other PEs
;  new translation table entry can be relied upon at this point and all accesses
;  generated by any observers affected by the broadcast TLBIMVAIS operation using
;  the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]         ; updates the translation table entry
DSB ISH               ; ensures visibility of the update to translation table walks
TLBI VAE1IS,  X10
DSB ISH               ; ensures completion of the TLB invalidation
ISB                   ; Note ISB is not broadcast and must be executed locally
                      ; on other PEs
;  new translation table entry can be relied upon at this point and all accesses
;  generated by any observers affected by the broadcast TLBIMVAIS operation using
;  the old mapping have been completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a `DSB` by the observer that performed the TLB maintenance instruction. The execution of a `DSB` by a different observer does not have this effect, even if the `DSB` is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the `DSB` that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

AArch32

P1

```
STR R11, [R1]         ; updates the translation table for the region being paged out
DSB                   ; ensures visibility of the update to translation table walks
TLBIMVAIS R10         ; invalidates the old entry
DSB                   ; ensures completion of the invalidation on all PEs
ISB                   ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                   ; ensures completion of the memory transfer (this could be part of
                      ; LoadMemoryFromBackingStore)
ICIALLUIS             ; also invalidates the branch predictor
DSB                   ; ensures completion of the instruction cache
                      ; and branch predictor invalidation
STR R9, [R1]          ; creates a new translation table entry with a new mapping
DSB                   ; ensures visibility of the new translation table mapping
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    ISB                 ; ensures synchronisation of this instruction stream
```

AArch64

P1

```
    STR X11, [X1]       ; updates the translation table for the region being paged out
    DSB ISH             ; ensures visibility of the update to translation table walks
    TLBI VAE1IS, X10    ; invalidates the old entry
    DSB ISH             ; ensures completion of the invalidation on all PEs
    ISB                 ; ensures visibility of the invalidation
    BL SaveMemoryPageToBackingStore
    BL LoadMemoryFromBackingStore
    DSB ISH             ; ensures completion of the memory transfer (this could be part of
                        ; LoadMemoryFromBackingStore)
    IC IALLUIS          ; also invalidates the branch predictor
    DSB ISH             ; ensures completion of the instruction cache
                        ; and branch predictor invalidation
    STR X9, [X1]        ; creates a new translation table entry with a new mapping
    DSB ISH             ; ensures visibility of the new translation table mapping
    ISB                 ; ensures synchronisation of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of ICIALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state and IC IVAU operations in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

Using break-before-make when updating translation table entries

The Arm Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make sequence when updating translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

The architecture requires use of a break-before make sequence in these situations, see *Using break-before-make when updating translation table entries* on page D5-2639 for more information. However, if software did not use a break-before-make approach, an implementation might give a result that would occur if the two reads to the same virtual address did not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE, running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read-write.

If the operating system changed the address mapping without going through an invalid entry, then it would be possible for a third PE to perform a write to the location that would be seen by the first load by the first PE, and not seen by the second load by the same PE.

The required break-before-make code sequence in this case is:

AArch32

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

P1

```
; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry
STRD R1, R2, [R3]          ; stores invalid entry
DSB ISH                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R4               ; invalidates the old entry
DSB ISH                    ; ensures completion of the invalidation on all PEs
ICIALLUIS                  ; also invalidates the branch predictor
STRD R5, R6, [R3]          ; store new mapping
DSB ISH                    ; ensures visibility of the update to translation table walks
ISB                        ; ensures synchronisation of this instruction stream
```

Note

This example shows an update to an entry in a translation table that is using the long-descriptor format.

AArch64

P1

```
; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry
STR X1, [X2]               ; stores invalid entry
DSB ISH                    ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X3            ; invalidates the old entry
DSB ISH                    ; ensures completion of the invalidation on all PEs
IC IALLUIS                 ; also invalidates the branch predictor
STR X4, [X2]               ; store new mapping
DSB ISH                    ; ensures visibility of the update to translation table walks
ISB                        ; ensures synchronisation of this instruction stream
```

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of `ICIALLUIS` in AArch32 state and `IC IALLUIS` in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` in AArch32 state, and `IC IVAU` in AArch64 state. This invalidation must be done when the mapping used for the `ICIMVAU` and `IC IVAU` operations is valid but not executable.

K11.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.
- When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a `DSB <domain>` instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

AArch32

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

P1

```
STR R5, [R2]          ; data written to the data buffer
DSB
STR R0, [R4]          ; R4 contains the address of the DMA control register
```

AArch64

P1

```
STR W5, [X2]          ; data written to the data buffer
DSB <domain>
STR W0, [X4]          ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a `DSB <domain>` between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

AArch32

P1

```
WAIT ([R4] == 1)      ; R4 contains the address of the status register,
                      ; and the value '1' indicates completion of the DMA transfer
DSB
LDR R5, [R2]          ; reads data from the data buffer
```

AArch64

P1

```
WAIT ([X4] == 1)      ; X4 contains the address of the status register,
                      ; and the value '1' indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2]          ; reads data from the data buffer
```

K11.6 Armv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the Armv7 compatible approaches for ordering, using DMB and DSB barriers:

- *Simple ordering and barrier cases*.
- *Load-Exclusive, Store-Exclusive and barriers* on page K11-7769.
- *Using a mailbox to send an interrupt* on page K11-7771.
- *Cache and TLB maintenance instructions and barriers* on page K11-7771.

K11.6.1 Simple ordering and barrier cases

Arm implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

Simple weakly consistent ordering example

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

Message passing

The following sections describe:

- *Weakly-ordered message passing problem*.
- *Message passing with multiple observers* on page K11-7766.

Weakly-ordered message passing problem

P1

```
STR R5, [R1]            ; sets new data
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)           ; waits on flag
LDR R5, [R1]            ; reads new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1]            ; sets new data
DMB [ST]                ; ensures all observers observe data before the flag
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)           ; waits on flag
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
DMB                     ; ensures that the load of data is after the flag has been observed
LDR R5, [R1]
```

Resolving by the use of barriers and address dependency

There is a rule within the Arm architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.

  Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.

  This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.

  Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K11-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

Table K11-1 Dependency examples

Address dependency		**Control dependency**		**Address and control dependency**[a]
(a)	**(b)**	**(c)**	**(d)**	**(e)**
`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`
`LDR r2, [r1]`	`AND r1, r1, #0`	`CMP r1, #55`	`CMP r1, #55`	`CMP r1, #0`
	`LDR r2, [r3, r1]`	`LDRNE r2, [r3]`	`MOVNE r4, #22`	`LDRNE r2, [r1]`
			`LDR r2, [r3, r4]`	

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page K11-7765 can also be satisfied as shown in the following example:

P1

```
STR R5, [R1]            ; sets new data
DMB [ST]                ; ensures all observers observe data before the flag
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a `DMB` to ensure that P2 does not observe the write of [R2] before the write of [R1].

Message passing with multiple observers

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

P1

```
STR R5, [R1]            ; sets new data
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

P3

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load is address depndent on R12
                        ; and so is ordered after the flag has been seen
```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value `0x55`:

P1

```
STR R5, [R1]            ; sets new data
DMB [ST]                ; ensures all observers observe data before the flag
STR R0, [R2]            ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is the destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

P3

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is the destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; the load has an address dependency on R12
                        ; and so is ordered after the flag has been seen
```

Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

P1

```
STR R5, [R1, #offset]   ; sets new data in a field
DMB [ST]                ; ensures all observers observe data before base address is updated
STR R1, [R2]            ; updates base address
```

P2

```
LDR R1, [R2]            ; reads for base address
CMP R1, #0              ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset]   ; uses base address to read field
```

If the null_trap is not taken, it is required that P2:R5==`0x55`. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.

P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

Posting a store before polling for acknowledgement

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

P1

```
STR R0, [R2]
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

In Armv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For Armv7 implementations with the Multiprocessing Extensions and for Armv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a `DMB` instruction prevents this deadlock in Armv7 implementations that do not include the Multiprocessing Extensions:

P1

```
STR R0, [R2]
DMB
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

The `DMB` executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

P1

```
STR R0, [R2]
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

In this example, the same deadlock can occur in Armv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a `DMB` instruction prevents this deadlock:

P1

```
STR R0, [R2]
DMB
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    ADD R0, R0, #1
    STR R0, [R2]
```

WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in *Posting a store before polling for acknowledgement* on page K11-7768, or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

P1

```
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

However, if the example in *Posting a store before polling for acknowledgement* on page K11-7768 is extended to include a WFE, there is no risk of a deadlock. The extended example is:

P1

```
    STR R0, [R2]
    DMB
Loop
    LDR R12, [R3]
    CMP R12, #1
    WFENE
    BNE Loop
```

P2

```
    WAIT ([R2]==1)
    STR R0, [R3]
    DSB
    SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see *Use of Wait For Event (WFE) and Send Event (SEV) with locks* on page K11-7770.

K11.6.2 Load-Exclusive, Store-Exclusive and barriers

The Load-Exclusive and Store-Exclusive instructions, described in *Synchronization and semaphores* on page B2-156, are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

P*x*

```
Loop
    LDREX R5, [R1]           ; reads lock
    CMP R5, #0               ; checks if 0
    STREXEQ R5, R0, [R1]     ; attempts to store new value
    CMPEQ R5, #0             ; tests if store succeeded
    BNE Loop                 ; retries if not
    DMB                      ; ensures that all subsequent accesses are observed after the
                             ; gaining of the lock is observed
    ; loads and stores in the critical region can now be performed
```

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

P*x*

```
    ; loads and stores in the critical region
    MOV R0, #0
    DMB                      ; ensures all previous accesses are observed before the lock is cleared
    STR R0, [R1]             ; clears the lock
```

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The Armv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or *spinlock*, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

P*x*

```
  Loop
   LDREX R5, [R1]           ; reads lock
   CMP R5, #0               ; checks if 0
   WFENE                    ; sleeps if the lock is held
   STREXEQ R5, R0, [R1]     ; attempts to store new value
   CMPEQ R5, #0             ; tests if store succeeded
   BNE Loop                 ; retries if not
   DMB                      ; ensures that all subsequent accesses are observed after the
                            ; gaining of the lock is observed
   ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code using SEV:

P*x*

```
    ; loads and stores in the critical region
    MOV R0, #0
    DMB                      ; ensures all previous accesses are observed before the lock is cleared
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
STR R0, [R1]            ; clears the lock
DSB                     ; ensures completion of the store that cleared the lock before
                        ; sending the event
SEV
```

K11.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

P1

```
STR R5, [R1]            ; message stored to shared memory location
DSB [ST]
STR R1, [R4]            ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

Note

The DSB executed by P1 ensures global observation of the store to [R1].The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

K11.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- *Data cache maintenance instructions*.
- *Instruction cache maintenance instructions* on page K11-7774.
- *TLB maintenance instructions and barriers* on page K11-7775.

Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- *Message passing to non-caching observers*.
- *Multiprocessing message passing to non-caching observers* on page K11-7772.
- *Invalidating DMA buffers, non-functional example* on page K11-7772.
- *Invalidating DMA buffers, functional example with single PE* on page K11-7773.
- *Invalidating DMA buffers, functional example with multiple coherent PEs* on page K11-7773.

Message passing to non-caching observers

The Armv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

P1

```
STR R5, [R1]            ; updates data (assumed to be in P1's cache)
DCCMVAC R1              ; cleans cache to point of coherency
DMB                     ; ensures effects of the clean will be observed before the flag is set
STR R0, [R4]            ; sends flag to external agent (Non-cacheable location)
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E1

```
WAIT ([R4] == 1)         ; waits for the flag
DMB                      ; ensures that flag has been seen before reading data
LDR R5, [R1]             ; reads the data
```

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions in Armv8, and in Armv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

P1

```
STR R5, [R1]             ; updates data (assumed to be in P1's cache)
DMB [ST]                 ; ensures new data is observed before the flag to P2 is set
STR R0, [R2]             ; sends flag to P2
```

P2

```
WAIT ([R2] == 1)         ; waits for flag from P1
DMB                      ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1               ; cleans cache to point of coherency - this cleans the cache of P1
DMB                      ; ensures effects of the clean are observed before the flag to E1 is set
STR R0, [R4]             ; sends flag to E1
```

E1

```
WAIT ([R4] == 1)         ; waits for flag from P2
DMB                      ; ensures that flag has been observed before reading the data
LDR R5, [R1]             ; reads the data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

P1

```
DCIMVAC R1               ; ensures caches are not dirty. A clean operation could be
                         ; used but the DMA overwrites this region so an invalidate operation
                         ; is sufficient and usually more efficient
DMB                      ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]             ; sends flag to external agent
WAIT ([R4]==1)           ; waits for a different flag from an external agent
DMB                      ; observes flag from external agent before reading new data. However [R1]
                         ; could have been brought into cache earlier
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)         ; waits for flag
STR R5, [R1]             ; stores new data
DMB
STR R0, [R4]             ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Invalidating DMA buffers, functional example with single PE

P1

```
DCIMVAC R1              ; ensures cache is not dirty. A clean operation could be
                        ; used but the DMA overwrites this region so an invalidate operation
                        ; is sufficient and usually more efficient
DMB                     ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]            ; sends flag to external agent
WAIT ([R4]==1)          ; waits for a different flag from an external agent
DMB                     ; ensures that cache invalidate is observed after the flag
                        ; from external agent is observed
DCIMVAC R1              ; ensures cache discards stale copies before use
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)        ; waits for flag
STR R5, [R1]            ; stores new data
DMB [ST]
STR R0, [R4]            ; sends a flag
```

In this example, the result P1:R5 == `0x55` is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of `DMB` instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
DMB
STR R0, [R2]            ; signals release of [R1]
WAIT ([R2] == 0)        ; waits for new value from DMA
DMB
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1)        ; waits for release of [R1] by P0
DCIMVAC R1              ; ensures caches are not dirty, invalidate is sufficient
DMB
STR R0, [R3]            ; requests new data for [R1]
WAIT ([R4] == 1)        ; waits for new data
DMB
DCIMVAC R1              ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]            ; signals availability of new [R1]
```

E1

```
WAIT ([R3] == 1)        ; waits for new data request
STR R5, [R1]            ; sends new [R1]
DMB [ST]
STR R0, [R4]            ; indicates new data available to P1
```

In this example, the result P0:R5 == `0x55` is required. The `DMB` issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The `DMB` issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- *Ensuring the visibility of updates to instructions for a uniprocessor*.
- *Ensuring the visibility of updates to instructions for a multiprocessor*.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a `DSB`, and an `ISB` is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB
ICIMVAU R1              ; ensures instruction cache and branch predictor discard stale data
BPIMVA R1
DSB                     ; ensures completion of the invalidation
ISB                     ; ensures instruction fetch path observes new instruction cache state
BX R1
```

Ensuring the visibility of updates to instructions for a multiprocessor

Armv8, and an Armv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An `ISB` is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own `ISB` synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB                     ; ensures completion of the clean on all processors
ICIMVAU R1              ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1
DSB                     ; ensures completion of the instruction cache and branch predictor
                        ; invalidation on all PEs
STR R0, [R2]            ; sets flag to signal completion
ISB                     ; synchronizes context on this PE
BX R1                   ; branches to new code
```

P2-P*x*

```
WAIT ([R2] == 1)        ; waits for flag signaling completion
ISB                     ; synchronizes context on this processor
BX R1                   ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
DSB                     ; ensure completion of the clean on all PEs
ICIMVAU R1              ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB                     ; ensure ordering of the store after the invalidation
                        ; DOES NOT guarantee completion of instruction cache/branch
                        ; predictor on other PEs
STR R0, [R2]            ; sets flag to signal completion
DSB                     ; ensures completion of the invalidation on all PEs
ISB                     ; synchronizes context on this PE
BX R1                   ; branches to new code
```

P2-P*x*

```
WAIT ([R2] == 1)        ; waits for flag signaling completion
DSB                     ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1
```

In this example, P2…P*x* might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- *Ensuring the visibility of updates to translation tables for a uniprocessor*.
- *Ensuring the visibility of updates to translation tables for a multiprocessor* on page K11-7776.
- *Paging memory in and out* on page K11-7776.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

In the Armv8 architecture, and in an Armv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a `DSB` and an `ISB`. Therefore, the code for updating a translation table entry is:

P1

```
STR R11, [R1]           ; updates the translation table entry
DSB                     ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                     ; ensures completion of the BP and TLB invalidation
ISB                     ; synchronizes context on this PE
;
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. In the Armv8 architecture, and in an Armv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a `DSB` that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

P1

```
STR R11, [R1]           ; updates the translation table entry
DSB                     ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                     ; ensures completion of the BP and TLB invalidation
ISB                     ; Note ISB is not broadcast and must be executed locally on other PEs
;
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a `DSB` by the observer that performed the TLB maintenance instruction. The execution of a `DSB` by a different observer does not have this effect, even if the `DSB` is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the `DSB` that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1]           ; updates the translation table for the region being paged out
DSB                     ; ensures visibility of the update to translation table walks
TLBIMVAIS R10           ; invalidates the old entry
DSB                     ; ensures completion of the invalidation on all processors
ISB                     ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                     ; ensures completion of the memory transfer (this could be part of
                        ; LoadMemoryFromBackingStore
ICIALLUIS               ; also invalidates the branch predictor
DSB                     ; ensures completion of the instruction cache
                        ; and branch predictor invalidation
STR R9, [R1]            ; creates a new translation table entry with a new mapping
DSB                     ; ensures visibility of the new translation table mapping
ISB                     ; ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In this example, the use of ICIALLUIS to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU operations. This invalidation must be done when the mapping used for the ICIMVAU operations is valid but not executable.

Appendix K12
Random Number Generation

This appendix provides further information on the generation of random numbers using ARMv8.5-RNG. It contains the following sections:

- *Properties of the generated random number* on page K12-7780.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K12.1 Properties of the generated random number

When ARMv8.5-RNG is implemented, reads to the RNDR and RNDRRS registers return a 64-bit random number. The random numbers must meet the properties and conform to the standards that are detailed in this section.

The output random number is from a Deterministic Random Bit Generator (DRBG), which is seeded from a True Random Number Generator (TRNG).

The TRNG provides entropy in the form of random numbers, from the sampled output of an unpredictable physical process.

The TRNG should conform to:

- The NIST SP800-90B standard.
- The NIST SP800-22 standard.
- The FIPS 140-2 standard.
- The BSI AIS-31 standard.

The DRBG produces random numbers from a cryptographically secure algorithm.

The DRBG is seeded from the TRNG.

The DRBG algorithm should conform to the NIST SP800-90A Rev 1 standard.

The DRBG is reseeded after an IMPLEMENTATION DEFINED number of random numbers has been generated and read using the RNDR register.

The DRBG is reseeded immediately before the random number is generated and read using the RNDRRS register.

The entire random number generation should conform to the NIST SP800-90C standard.

Note

Since a TRNG can only generate random bits at a limited rate, the random number bits are commonly collected in an “entropy pool” until needed. An implementation should ensure that lower privileged software cannot impact the performance of higher privileged software by entirely draining this “entropy pool”. The refill time cost of the “entropy pool” should be paid for by the persistent caller.

Appendix K13
Arm Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some *helper* procedures and functions that are used by pseudocode. It contains the following sections:

- *About the Arm pseudocode* on page K13-7782.
- *Pseudocode for instruction descriptions* on page K13-7783.
- *Data types* on page K13-7785.
- *Operators* on page K13-7790.
- *Statements and control structures* on page K13-7796.
- *Built-in functions* on page K13-7801.
- *Miscellaneous helper procedures and functions* on page K13-7804.
- *Arm pseudocode definition index* on page K13-7806.

Note

This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of Arm pseudocode. This appendix is not complete. Changes are planned for future releases.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.

K13.1 About the Arm pseudocode

The Arm pseudocode provides precise descriptions of some areas of the Arm architecture. This includes description of the decoding and operation of all valid instructions. *Pseudocode for instruction descriptions* on page K13-7783 gives general information about this instruction pseudocode, including its limitations.

The following sections describe the Arm pseudocode in detail:

- *Data types* on page K13-7785.
- *Operators* on page K13-7790.
- *Statements and control structures* on page K13-7796.

Built-in functions on page K13-7801 and *Miscellaneous helper procedures and functions* on page K13-7804 describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. *Arm pseudocode definition index* on page K13-7806 contains the indexes to the pseudocode.

K13.1.1 General limitations of Arm pseudocode

The pseudocode statements `IMPLEMENTATION_DEFINED`, `SEE`, `UNDEFINED`, and `UNPREDICTABLE` indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs.

For more information, see *Special statements* on page K13-7800.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K13.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in *General limitations of Arm pseudocode* on page K13-7782 and *Limitations of the instruction pseudocode* on page K13-7784.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. *Instruction encoding diagrams and instruction pseudocode* gives more information about the pseudocode provided for each instruction.

K13.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.
- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function, either at its start or only after a condition code check performed by `if ConditionPassed() then`.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A *should be* 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is CONSTRAINED UNPREDICTABLE. For more information, see *SBZ or SBO fields T32 and A32 in instructions* on page K1-7610.
- A named single bit or a bit in a named multi-bit field. The `cond` field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.
- The encoding diagram is for an A32/T32 instruction that does not have a `cond` field in bits[31:28].
- The encoding diagram is for an A32/T32 instruction that has a `cond` field in bits[31:28], and bits[31:28] of the instruction are not `0b1111`.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.
2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.
3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the `Consistent()` function to specify what happens if they are not identical. `Consistent()` returns `TRUE` if all instruction bits or fields with the same name as its argument have the same value, and `FALSE` otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is CONSTRAINED UNPREDICTABLE. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as CONSTRAINED UNPREDICTABLE, see *SBZ or SBO fields T32 and A32 in instructions* on page K1-7610.

5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The `ConditionPassed()` call in the common pseudocode, if present, performs step 2, and the `EncodingSpecificOperations()` call performs steps 3 and 4.

K13.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see *Ordering constraints* on page E2-3818.

- Pseudocode does not describe the exact rules when an UNDEFINED instruction fails its condition code check. In such cases, the `UNDEFINED` pseudocode statement lies inside the `if ConditionPassed() then …` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a NOP. *Conditional execution of undefined instructions* on page G1-5538 describes the exact rules.

- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. *Combinations of floating-point exceptions* on page E1-3798 describes the exact rules.

  Note

  There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an `LDM` instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-5501.

K13.3 Data types

This section describes:

- *General data type rules*.
- *Bitstrings*.
- *Integers* on page K13-7786.
- *Reals* on page K13-7786.
- *Booleans* on page K13-7786.
- *Enumerations* on page K13-7787.
- *Structures* on page K13-7787.
- *Tuples* on page K13-7788.
- *Arrays* on page K13-7789.

K13.3.1 General data type rules

Arm architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables `x`, `y` and `z` to have types integer, bitstring of length 1, and Boolean, respectively.

```
x = 1;
y = '1';
z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named `count` is an integer.

```
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

K13.3.2 Bitstrings

This section describes the bitstring data type.

Syntax

`bits(N)`	The type name of a bitstring of length `N`.
`bit`	A synonym of `bits(1)`.

Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type `bit` are `'0'` and `'1'`. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right *N*-1 to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit *N*-1 is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length `N` is bit (*N*–1) and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

K13.3.3 Integers

This section describes the data type for integer numbers.

Syntax

`integer` The type name for the integer data type.

Description

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as `0`, `15`, `-1234`. They can also be written in C-style hexadecimal form, such as `0x55` or `0x80000000`. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, `0x80000000` is the integer $+2^{31}$. If -2^{31} needs to be written in hexadecimal, it must be written as `-0x80000000`.

K13.3.4 Reals

This section describes the data type for real numbers.

Syntax

`real` The type name for the real data type.

Description

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means `0` is an integer constant literal, but `0.0` is a real constant literal.

K13.3.5 Booleans

This section describes the Boolean data type.

Syntax

`boolean` The type name for the Boolean data type.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`TRUE` The two values a Boolean variable can take.

Description

A Boolean is a logical `TRUE` or `FALSE` value.

Note

This is not the same type as `bit`, which is a bitstring of length 1. A Boolean can only take on one of two values: `TRUE` or `FALSE`.

K13.3.6 Enumerations

This section describes the enumeration data type.

Syntax and examples

`enumeration` Keyword to defined a new enumeration type.

```
enumeration Example {Example_One, Example_Two, Example_Three};
```

A definition of a new enumeration called `Example`, which can take on the values `Example_One`, `Example_Two`, `Example_Three`.

Description

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the named values are its possible *values*.

K13.3.7 Structures

This section describes the structure data type.

Syntax and examples

`type` The keyword used to declare the structure data type.

```
type ShiftSpec is (bits(2) shift, integer amount)
```

An example definition for a new structure called `ShiftSpec` that contains an bitstring member called `shift` and a integer member named `amount`. Structure definitions must not be terminated with a semicolon.

```
ShiftSpec abc;
```

A declaration of a variable named `abc` of type `ShiftSpec`.

```
abc.shift
```

Syntax to refer to the individual members within the structure variable.

Description

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In the syntax section, the example defines a structure called `ShiftSpec` with two members. The first is a bitstring of length 2 named `shift` and the second is an integer named `amount`. After declaring a variable of that type named `abc`, the members of this structure are referred to as `abc.shift` and `abc.amount`.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

`ShiftSpec1` and `ShiftSpec2` are two different types despite having identical definitions. This means that the value in a variable of type `ShiftSpec1` cannot be assigned to variable of type `ShiftSpec2`.

K13.3.8 Tuples

This section describes the tuple data type.

Examples

```
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)` and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K13.3.9 Arrays

This section describes the array data type.

Syntax

`array` The type name for the array data type.

```
array data_type array_name[A..B];
```

Declaration of an array of type `data_type`, which might be compound data type. It is named `array_name` and is indexed with an integer range from `A` to `B`.

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then `..`, then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

```
array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as `R[i]`, `MemU[address, size]` or `Elem[vector, i, size]`. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See *Function and procedure calls* on page K13-7796.

K13.4 Operators

This section describes:

- *Relational operators*.
- *Boolean operators*.
- *Bitstring operators* on page K13-7791.
- *Arithmetic operators* on page K13-7791.
- *The assignment operator* on page K13-7792.
- *Precedence rules* on page K13-7794.
- *Conditional expressions* on page K13-7794.
- *Operator polymorphism* on page K13-7794.

K13.4.1 Relational operators

The following operations yield results of type `boolean`.

Equality and non-equality

If two variables `x` and `y` are of the same type, their values can be tested for equality by using the expression `x == y` and for non-equality by using the expression `x != y`. In both cases, the result is of type `boolean`.

Both `x` and `y` must be of type `bits(N)`, `real`, `enumeration`, `boolean`, or `integer`. Named values from an `enumeration` can only be compared if they are both from the same `enumeration`. An exception is that a bitstring can be tested for equality with an integer to allow a `d==15` test.

A special form of comparison is defined with a bitstring literal that can contain bit values `'0'`, `'1'`, and `'x'`. Any bit with value `'x'` is ignored in determining the result of the comparison. For example, if `opcode` is a 4-bit bitstring, the expression `opcode == '1x0x'` matches the values `'1000'`, `'1100'`, `'1001'`, and `'1101'`. This is known as a bitmask.

Note

This special form is permitted in the implied equality comparisons in the `when` parts of `case … of …` structures.

Comparisons

If `x` and `y` are integers or reals, then `x < y`, `x <= y`, `x > y`, and `x >= y` are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

Set membership with `IN`

`<expression> IN {<set>}` produces `TRUE` if `<expression>` is a member of `<set>`. Otherwise, it is `FALSE`. `<set>` must be a list of expressions separated by commas.

K13.4.2 Boolean operators

If `x` is a Boolean expression, then `!x` is its logical inverse.

If `x` and `y` are Boolean expressions, then `x && y` is the result of ANDing them together. As in the C language, if `x` is `FALSE`, the result is determined to be `FALSE` without evaluating `y`.

Note

This is known as short circuit evaluation.

If `x` and `y` are `booleans`, then `x || y` is the result of ORing them together. As in the C language, if `x` is `TRUE`, the result is determined to be `TRUE` without evaluating `y`.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If x and y are booleans or Boolean expressions, then the result of `x != y` is the same as the result of exclusive-ORing x and y together. The operator `EOR` only accepts bitstring arguments.

K13.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

Logical operations on bitstrings

If x is a bitstring, `NOT(x)` is the bitstring of the same length obtained by logically inverting every bit of x.

If x and y are bitstrings of the same length, `x AND y`, `x OR y`, and `x EOR y` are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of x and y together.

Bitstring concatenation and slicing

If x and y are bitstrings of lengths `N` and `M` respectively, then `x:y` is the bitstring of length `N+M` constructed by concatenating x and y in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is `x<integer_list>`, where x is the integer or bitstring being sliced, and `<integer_list>` is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in `<integer_list>`. In `x<integer_list>`, each of the integers in `<integer_list>` must be:

- `>= 0`.
- `< Len(x)` if x is a bitstring.

The definition of `x<integer_list>` depends on whether `integer_list` contains more than one integer:

- If `integer_list` contains more than one integer, `x<i, j, k,…, n>` is defined to be the concatenation:

  `x<i> : x<j> : x<k> : … : x<n>`.

- If `integer_list` consists of just one integer `i`, `x<i>` is defined to be:
  - If x is a bitstring, `'0'` if bit `i` of x is a zero and `'1'` if bit `i` of x is a one.
  - If x is an integer, and y is the unique integer in the range `0` to `2^(i+1)-1` that is congruent to x modulo `2^(i+1)`. Then `x<i>` is `'0'` if `y < 2^i` and `'1'` if `y >= 2^i`.

    Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

The notation for a range expression is `i:j` with `i >= j` is shorthand for the integers in order from `i` down to `j`, with both end values included. For example, `instr<31:28>` represents `instr<31, 30, 29, 28>`.

`x<integer_list>` is assignable provided x is an assignable bitstring and no integer appears more than once in `<integer_list>`. In particular, `x<i>` is assignable if x is an assignable bitstring and `0 <= i < Len(x)`.

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as `N`. In such cases, the syntax `APSR.N` is used as a more readable synonym for `APSR<31>` as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, `APSR.<N, C, Q>` is synonymous with `APSR <31, 29, 27>`.

K13.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Unary plus and minus

If x is an integer or real, then +x is x unchanged, -x is x with its sign reversed. Both are of the same type as x.

Addition and subtraction

If x and y are integers or reals, x+y and x-y are their sum and difference. Both are of type `integer` if x and y are both of type `integer`, and `real` otherwise.

There are two cases where the types of x and y can be different. A bitstring and an integer can be added together to allow the operation `PC + 4`. An integer can be subtracted from a bitstring to allow the operation `PC - 2`.

If x and y are bitstrings of the same length `N`, so that `N = Len(x) = Len(y)`, then x+y and x-y are the least significant *N* bits of the results of converting x and y to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

```
x+y = (SInt(x) + SInt(y))<N-1:0>
    = (UInt(x) + UInt(y))<N-1:0>
x-y = (SInt(x) - SInt(y))<N-1:0>
    = (UInt(x) - UInt(y))<N-1:0>
```

If x is a bitstring of length `N` and y is an integer, x+y and x-y are the bitstrings of length `N` defined by `x+y = x + y<N-1:0>` and `x-y = x - y<N-1:0>`. Similarly, if x is an integer and y is a bitstring of length `M`, x+y and x-y are the bitstrings of length `M` defined by `x+y = x<M-1:0> + y` and `x-y = x<M-1:0> - y`.

Multiplication

If x and y are integers or reals, then `x * y` is the product of x and y. It is of type `integer` if x and y are both of type `integer`, and `real` otherwise.

Division and modulo

If x and y are reals, then x/y is the result of dividing x by y, and is always of type `real`.

If x and y are integers, then `x DIV y` and `x MOD y` are defined by:

```
x DIV y = RoundDown(x/y)
x MOD y = x - y * (x DIV y)
```

It is a pseudocode error to use any of x/y, `x MOD y`, or `x DIV y` in any context where y can be zero.

Scaling

If x and n are of type `integer`, then:

- `x << n = RoundDown(x * 2^n)`.
- `x >> n = RoundDown(x * 2^(-n))`.

Raising to a power

If x is an integer or a real and n is an integer then x^n is the result of raising x to the power of n, and:

- If x is of type `integer` then x^n is of type `integer`.
- If x is of type `real` then x^n is of type `real`.

K13.4.5 The assignment operator

The assignment operator is the = character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

```
<assignable_expression> = <expression>;
```

This following subsection defines valid expression syntax.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

General expression syntax

An expression is one of the following:

- A literal.
- A variable, optionally preceded by a data type name to declare its type.
- The word `UNKNOWN` preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an Arm architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or `CONSTRAINED UNPREDICTABLE` and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

Note

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.

  The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

Note

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as - to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
  - An optional preceding data type name.
  - A data type the variable was given earlier in the pseudocode by recursive application of this rule.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

K13.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see *Boolean operators* on page K13-7790.
2. Operators on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if `i`, `j` and `k` are integer variables, `i > 0 && j > 0 && k > 0` is acceptable, but `i > 0 && j > 0 || k > 0` is not.

K13.4.7 Conditional expressions

If `x` and `y` are two values of the same type and `t` is a value of type `boolean`, then `if t then x else y` is an expression of the same type as `x` and `y` that produces `x` if `t` is `TRUE` and `y` if `t` is `FALSE`.

K13.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator `+` has forms that act on various combinations of integers, reals and bitstrings.

Table K13-1 summarizes the operand types valid for each unary operator and the result type. Table K13-2 on page K13-7795 summarizes the operand types valid for each binary operator and the result type.

Table K13-1 Result and operand types permitted for unary operators

Operator	Operand Type	Result Type
-	`integer`	`integer`
	`real`	`real`
`NOT`	`bits(N)`	`bits(N)`
`!`	`boolean`	`boolean`

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table K13-2 Result and operand types permitted for binary operators

Operator	First operand type	Second operand type	Result type
==	bits(N)	integer	boolean
		bits(N)	
	integer	integer	
	real	real	
	enumeration	enumeration	
	boolean	boolean	
!=	bits(N)	bits(N)	boolean
	integer	integer	
	real	real	
<, > <= , >=	integer	integer	boolean
	real	real	
+, -	integer	integer	integer
	real	real	real
	bits(N)	bits(N)	bits(N)
		integer	
<<, >>	integer	integer	integer
*	integer	integer	integer
	real	real	real
	bits(N)	bits(N)	bits(N)
/	real	real	real
DIV	integer	integer	integer
MOD	integer	integer	integer
	bits(N)	integer	
&&, ||	boolean	boolean	boolean
AND, OR, EOR	bits(N)	bits(N)	bits(N)
^	integer	integer	integer
	real	integer	real

K13.5 Statements and control structures

This section describes the statements and program structures available in the pseudocode:

- *Statements and Indentation*.
- *Function and procedure calls*.
- *Conditional control structures* on page K13-7798.
- *Loop control structures* on page K13-7799.
- *Special statements* on page K13-7800.
- *Comments* on page K13-7800.

K13.5.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as `if … then … else …` or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

K13.5.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Procedure and function definitions

A procedure definition has the form:

```
<procedure name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

where `<argument prototypes>` consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

Note

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```
<return type> <function name>(<argument prototypes>)
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

Note

A function or procedure name can include a "`.`". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

```
<return type> <function name>[<argument prototypes>]
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

Its related function definition with no return type is equivalent to writing to an array. For example:

```
<function name>[<argument prototypes>] = <value prototype>
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

```
<procedure_name>(<arguments>);
```

Return statements

A procedure return has the form:

```
return;
```

A function return has the form:

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
return <expression>;
```

where `<expression>` is of the type declared in the function prototype line.

K13.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

if … then … else …

In addition to being a ternary operator, a multi-line `if … then … else …` structure can act as a control structure and has the form:

```
if <boolean_expression> then
    <statement 1>;
    <statement 2>;
    …
    <statement n>;

elsif <boolean_expression> then
    <statement a>;
    <statement b>;
    …
    <statement z>;
else
    <statement A>;
    <statement B>;
    …
    <statement Z>;
```

The block of lines consisting of `elsif` and its indented statements is optional, and multiple `elsif` blocks can be used.

The block of lines consisting of `else` and its indented statements is optional.

Abbreviated one-line forms can be used when the `then` part, and in the `else` part if it is present, contain only simple statements such as:

```
if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;
```

Note

In these forms, `<statement 1>`, `<statement 2>` and `<statement A>` must be terminated by semicolons. This and the fact that the `else` part is optional distinguish its use as a control structure from its use as a ternary operator.

case … of …

A `case … of …` structure has the form:

```
case <expression> of
    when <literal values1>
        <statement 1>;
        <statement 2>;
        …
        <statement n>;

    when <literal values2>
        <statement 1>;
        <statement 2>;
        …
        <statement n>;

    … more "when" groups if required …
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    otherwise
        <statement A>;
        <statement B>;
        …
        <statement Z>;
```

In this structure, <literal values1> and <literal values2> consist of literal values of the same type as <expression>, separated by commas. There can be additional when groups in the structure. Abbreviated one line forms of when and otherwise parts can be used when they contain only simple statements.

If <expression> has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details see *Equality and non-equality* on page K13-7790.

K13.5.4 Loop control structures

This section describes the three loop control structures used in the pseudocode.

repeat … until …

A repeat … until … structure has the form:

```
repeat
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
until <boolean_expression>;
```

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

while … do

A while … do structure has the form:

```
while <boolean_expression> do
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

for …

A for … structure has the form:

```
for <assignable_expression> = <integer_expr1> to <integer_expr2>
    <statement 1>;
    <statement 2>;
    …
    <statement n>;
```

The <assignable_expression> is initialized to <integer_expr1> and compared to <integer_expr2>. If <integer_expr1> is less than <integer_expr2>, the loop body is executed and the <assignable_expression> incremented by one. This repeats until <assignable expression> is more than or equal to <integer_expr2>.

There is an alternate form:

```
for <assignable_expression> = <integer_expr1> downto <integer_expr2>
```

where <integer_expr1> is decremented after the loop body executes and continues until <assignable expression> is less than or equal than <integer_expr2>.

K13.5.5 Special statements

This section describes statements with particular architecturally-defined behaviors.

UNDEFINED

This subsection describes the statement:

```
UNDEFINED;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

UNPREDICTABLE

This subsection describes the statement:

```
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

SEE…

This subsection describes the statement:

```
SEE <reference>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The `<reference>` indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

IMPLEMENTATION_DEFINED

This subsection describes the statement:

```
IMPLEMENTATION_DEFINED {"<text>"};
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION DEFINED. An optional `<text>` field can give more information.

K13.5.6 Comments

The pseudocode supports two styles of comments:

- `//` starts a comment that is terminated by the end of the line.
- `/*` starts a comment that is terminated by `*/`.

`/**/` statements might not be nested, and the first `*/` ends the comment.

Note

Comment lines do not require a terminating semicolon.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K13.6 Built-in functions

This section describes:

- *Bitstring manipulation functions*.
- *Arithmetic functions* on page K13-7802.

K13.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

Bitstring length and most significant bit

If x is a bitstring:

- The bitstring length function `Len(x)` returns the length of x as an integer.

Bitstring concatenation and replication

If x is a bitstring and n is an integer with `n >= 0`:

- `Replicate(x, n)` is the bitstring of length `n*Len(x)` consisting of n copies of x concatenated together.
- `Zeros(n)` = `Replicate('0', n)`.
- `Ones(n)` = `Replicate('1', n)`.

Bitstring count

If x is a bitstring, `BitCount(x)` is an integer result equal to the number of bits of x that are ones.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Testing a bitstring for being all zero or all ones

If x is a bitstring:

- `IsZero(x)` produces `TRUE` if all of the bits of x are zeros and `FALSE` if any of them are ones
- `IsZeroBit(x)` produces `'1'` if all of the bits of x are zeros and `'0'` if any of them are ones.

`IsOnes(x)` and `IsOnesBit(x)` work in the corresponding ways. This means:

```
IsZero(x)    = (BitCount(x) == 0)
IsOnes(x)    = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'
```

Lowest and highest set bits of a bitstring

If x is a bitstring, and `N = Len(x)`:

- `LowestSetBit(x)` is the minimum bit number of any of the bits of x that are ones. If all of its bits are zeros, `LowestSetBit(x) = N`.
- `HighestSetBit(x)` is the maximum bit number of any of the bits of x that are ones. If all of its bits are zeros, `HighestSetBit(x) = -1`.
- `CountLeadingZeroBits(x)` is the number of zero bits at the left end of x, in the range 0 to *N*. This means:

  `CountLeadingZeroBits(x) = N - 1 - HighestSetBit(x)`.
- `CountLeadingSignBits(x)` is the number of copies of the sign bit of x at the left end of x, excluding the sign bit itself, and is in the range 0 to *N*-1. This means:

  `CountLeadingSignBits(x) = CountLeadingZeroBits(x<N-1:1> EOR x<N-2:0>)`.

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then `ZeroExtend(x, i)` is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if `i == Len(x)`, then `ZeroExtend(x, i) = x`, and if `i > Len(x)`, then:

```
ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x
```

If x is a bitstring and i is an integer, then `SignExtend(x, i)` is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if `i == Len(x)`, then `SignExtend(x, i) = x`, and if `i > Len(x)`, then:

```
SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x
```

It is a pseudocode error to use either `ZeroExtend(x, i)` or `SignExtend(x, i)` in a context where it is possible that `i < Len(x)`.

Converting bitstrings to integers

If x is a bitstring, `SInt()` is the integer whose two's complement representation is x.

`UInt()` is the integer whose unsigned representation is x.

`Int(x, unsigned)` returns either `SInt(x)` or `UInt(x)` depending on the value of its second argument.

K13.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

Absolute value

If x is either of type real or integer, `Abs(x)` returns the absolute value of x. The result is the same type as x.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Rounding and aligning

If x is a real:

- `RoundDown(x)` produces the largest integer `n` such that `n <= x`.
- `RoundUp(x)` produces the smallest integer `n` such that `n >= x`.
- `RoundTowardsZero(x)` produces:
  - `RoundDown(x)` if `x > 0.0`.
  - `0` if `x == 0.0`.
  - `RoundUp(x)` if `x < 0.0`.

If x and y are both of type `integer`, `Align(x, y) = y * (x DIV y)`, and is of type `integer`.

If x is of type `bitstring` and y is of type `integer`, `Align(x, y) = (Align(UInt(x), y))<Len(x)-1:0>`, and is a `bitstring` of the same length as x.

It is a pseudocode error to use either form of `Align(x, y)` in any context where y can be 0. In practice, `Align(x, y)` is only used with y a constant power of two, and the bitstring form used with `y = 2^n` has the effect of producing its argument with its n low-order bits forced to zero.

Maximum and minimum

If x and y are integers or reals, then `Max(x, y)` and `Min(x, y)` are their maximum and minimum respectively. x and y must both be of type integer or of type real. The function returns a value of the same type as its operands.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K13.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous *helper* procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

Note

Chapter J1 *Armv8 Pseudocode* also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in Chapter J1 this section will be removed from the manual.

K13.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

```
EndOfInstruction();
```

K13.7.2 Hint_Debug()

This procedure supplies a hint to the debug system.

```
Hint_Debug(bits(4) option);
```

K13.7.3 Hint_PreloadData()

This procedure performs a *preload data* hint.

```
Hint_PreloadData(bits(32) address);
```

K13.7.4 Hint_PreloadDataForWrite()

This procedure performs a *preload data* hint with a probability that the use will be for a write.

```
Hint_PreloadDataForWrite(bits(32) address);
```

K13.7.5 Hint_PreloadInstr()

This procedure performs a *preload instructions* hint.

```
Hint_PreloadInstr(bits(32) address);
```

K13.7.6 Hint_Yield()

This procedure performs a *Yield* hint.

```
Hint_Yield();
```

K13.7.7 IsExternalAbort()

This function returns `TRUE` if the abort currently being processed is an External abort and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsExternalAbort(Fault type)
    assert type != Fault_None;

boolean IsExternalAbort(FaultRecord fault);
```

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

K13.7.8 IsAsyncAbort()

This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsAsyncAbort(Fault type)
    assert type != Fault_None;

boolean IsAsyncAbort(FaultRecord fault);
```

K13.7.9 LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the HSR.

```
bits(11) LSInstructionSyndrome();
```

K13.7.10 ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

```
integer ProcessorID();
```

K13.7.11 RemapRegsHaveResetValues()

This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and FALSE otherwise.

```
boolean RemapRegsHaveResetValues();
```

K13.7.12 ResetControlRegisters()

This function resets the System registers and memory-mapped control registers that have architecturally-defined reset values to those values. For more information about the affected registers see:

- *PE state on reset to AArch64 state* on page D1-2290.
- *PE state on reset into AArch32 state* on page G1-5559.

```
AArch64.ResetControlRegisters(boolean ResetIsCold)
AArch32.ResetControlRegisters(boolean ResetIsCold)
```

K13.7.13 ThisInstr()

This function returns the bitstring encoding of the currently-executing instruction.

```
bits(32) ThisInstr();
```

Note

Currently, this function is used only on 32-bit instruction encodings.

K13.7.14 ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

```
integer ThisInstrLength();
```

K13.8 Arm pseudocode definition index

This section contains the following tables:

- Table K13-3 which contains the pseudocode data types.
- Table K13-4 which contains the pseudocode operators.
- Table K13-5 on page K13-7807 which contains the pseudocode keywords and control structures.
- Table K13-6 on page K13-7808 which contains the statements with special behaviors.

Table K13-3 Index of pseudocode data types

Keyword	Meaning
`array`	Type name for the array type
`bit`	Keyword equivalent to `bits(1)`
`bits(N)`	Type name for the bitstring of length `N` data type
`boolean`	Type name for the Boolean data type
`enumeration`	Keyword to define a new enumeration type
`integer`	Type name for the integer data type
`real`	Type name for the real data type
`type`	Keyword to define a new structure

Table K13-4 Index of pseudocode operators

Operator	Meaning
`-`	Unary minus on integers or reals
	Subtraction of integers, reals and bitstrings
	Used in the left-hand side of an assignment or a tuple to discard the result
`+`	Unary plus on integers or reals
	Addition of integers, reals and bitstrings
`.`	Extract named member from a list
	Extract named bit or field from a register
`:`	Bitstring concatenation
	Integer range in bitstring extraction operator
`!`	Boolean NOT
`!=`	Comparison for inequality
`(…)`	Around arguments of procedure or function
`[…]`	Around array index
	Around arguments of array-like function
`*`	Multiplication of integers, reals, and bitstrings
`/`	Division of reals

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table K13-4 Index of pseudocode operators (continued)

Operator	Meaning
`&&`	Boolean AND
`<`	*Less than* comparison of integers and reals
`<…>`	Slicing of specified bits of bitstring or integer
`<<`	Multiply integer by power of 2
`<=`	*Less than or equal* comparison of integers and reals
`=`	Assignment operator
`==`	Comparison for equality
`>`	*Greater than* comparison of integers and reals
`>=`	*Greater than or equal* comparison of integers and reals
`>>`	Divide integer by power of 2
`||`	Boolean OR
`^`	Exponential operator
`AND`	Bitwise AND of bitstrings
`DIV`	Quotient from integer division
`EOR`	Bitwise EOR of bitstrings
`IN`	Tests membership of a certain expression in a set of values
`MOD`	Remainder from integer division
`NOT`	Bitwise inversion of bitstrings
`OR`	Bitwise OR of bitstrings
`case … of …`	Control structure for the
`if … then … else …`	Condition expression selecting between two values

Table K13-5 Index of pseudocode keywords and control structures

Operator	Meaning
`/*…*/`	Comment delimiters
`//`	Introduces comment terminated by end of line
`FALSE`	One of two values a Boolean can take (other than `TRUE`)
`for … = …to …`	Loop control structure, counting up from the initial value to the upper limit
`for … = … downto …`	Loop control structure, counting down from the initial value to the lower limit
`if … then … else …`	Conditional control structure
`otherwise`	Introduces default case in `case … of …` control structure

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table K13-5 Index of pseudocode keywords and control structures (continued)

Operator	Meaning
`repeat … until …`	Loop control structure that runs at least once until the termination condition is satisfied
`return`	Procedure or function return
`TRUE`	One of two values a Boolean can take (other than `FALSE`)
`when`	Introduces specific case in `case … of …` control structure
`while … do …`	Loop control structure that runs until the termination condition is satisfied

Table K13-6 Index of special statements

Keyword	Meaning
`IMPLEMENTATION_DEFINED`	Describes IMPLEMENTATION DEFINED behavior
`SEE`	Points to other pseudocode to use instead
`UNDEFINED`	Cause Undefined Instruction exception
`UNKNOWN`	Unspecified value
`UNPREDICTABLE`	Unspecified behavior

Appendix K14
Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- *Introduction and register disambiguation* on page K14-7810.
- *Alphabetical index of AArch64 registers and System instructions* on page K14-7815.
- *Functional index of AArch64 registers and System instructions* on page K14-7830.
- *Alphabetical index of AArch32 registers and System instructions* on page K14-7845.
- *Functional index of AArch32 registers and System instructions* on page K14-7855.
- *Alphabetical index of memory-mapped registers* on page K14-7867.
- *Functional index of memory-mapped registers* on page K14-7874.

K14.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception. level suffix, _EL0, _EL1, _EL2, or _EL3.

The following sections disambiguate the general register names:

- *Register name disambiguation by Execution state*.
- *Register name disambiguation by Exception level* on page K14-7814.

K14.1.1 Register name disambiguation by Execution state

Table K14-1 disambiguates the general names of the registers by Execution state.

Table K14-1 Disambiguation of general names of registers by Execution state

General name	Short description	AArch64 register	AArch32 register
CONTEXTIDR	Context ID	CONTEXTIDR_EL1	CONTEXTIDR
DBGBCR	Debug Breakpoint Control Registers	DBGBCR<n>_EL1	DBGBCR<n>
DBGBVR	Debug Breakpoint Value Registers	DBGBVR<n>_EL1	DBGBVR<n> DBGBXVR<n>
DBGCLAIMCLR	Debug CLAIM Tag Clear register	DBGCLAIMCLR_EL1	DBGCLAIMCLR
DBGCLAIMSET	Debug CLAIM Tag Set register	DBGCLAIMSET_EL1	DBGCLAIMSET
DBGDTRRX	Debug Data Transfer Register, Receive	DBGDTRRX_EL0	DBGDTRRXint
DBGDTRTX	Debug Data Transfer Register, Transmit	DBGDTRTX_EL0	DBGDTRTXint
DBGPRCR	Debug Power Control Register	DBGPRCR_EL1	DBGPRCR
DBGVCR	Debug Vector Catch Register	DBGVCR32_EL2	DBGVCR
DBGWCR	Debug Watchpoint Control Registers	DBGWCR<n>_EL1	DBGWCR<n>
DBGWVR	Debug Watchpoint Value Registers	DBGWVR<n>_EL1	DBGWVR<n>
DCCINT	Debug Comms Channel Interrupt Enable Register	MDCCINT_EL1	DBGDCCINT
DCCSR	Debug Comms Channel Status Register	MDCCSR_EL0	DBGDSCRint
DBGAUTHSTATUS	Debug Authentication Status	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS
DLR	Debug Link Register	DLR_EL0[31:0]	DLR
DSCR	Debug System Control Register	MDSCR_EL1	DBGDSCRext
DSPSR	Debug Saved PE State Register	DSPSR_EL0	DSPSR
FAR	Fault Address Register	FAR_EL1 FAR_EL2 FAR_EL3 HPFAR_EL2	DFAR, IFAR HDFAR, HIFAR FAR_EL3 HPFAR

Table K14-1 Disambiguation of general names of registers by Execution state (continued)

General name	Short description	AArch64 register	AArch32 register
HCR	Hypervisor Configuration Register	HCR_EL2	HCR HCR2
HDCR	Hyp or EL2 Debug Control Register	MDCR_EL2	HDCR
HSCTLR	Hypervisor System Control Register	SCTLR_EL2	HSCTLR
HTTBR	EL2 Translation Table Base Register	TTBR0_EL2	HTTBR
ISR	Interrupt Status Register	ISR_EL1	ISR
MPIDR	Multiprocessor Affinity Register	MPIDR_EL1	MPIDR
OSDLR	OS Double-Lock Register	OSDLR_EL1	DBGOSDLR
OSDTRRX	OS Lock Data Transfer Register, Receive	OSDTRRX_EL1	DBGDTRRXext
OSDTRTX	OS Lock Data Transfer Register, Transmit	OSDTRTX_EL1	DBGDTRTXext
OSECCR	OS Lock Exception Catch Control Register	OSECCR_EL1	DBGOSECCR
OSLAR	OS Lock Access Register	OSLAR_EL1	DBGOSLAR
OSLSR	OS Lock Status Register	OSLSR_EL1	DBGOSLSR
PMMIR	Performance Monitors Machine Identification Register	PMMIR_EL1	PMMIR
SCR	Secure Configuration Register	SCR_EL3	SCR
SCTLR	System Control Register	SCTLR_EL1 SCTLR_EL2 SCTLR_EL3	SCTLR (NS) HSCTLR SCTLR (S)
SDCR	Secure or EL3 Debug Configuration Register	MDCR_EL3	SDCR
SDER	Secure Debug Enable Register	SDER32_EL3	SDER
SPSR	Saved Program Status Register	SPSR_EL1 SPSR_EL2 SPSR_EL3	SPSR (general description) SPSR_abt SPSR_fiq SPSR_hyp SPSR_irq SPSR_mon SPSR_svc SPSR_und
TCR	Translation Control Register	TCR_EL1 TCR_EL2 TCR_EL3 VTCR_EL2	TTBCR(NS) HTCR TTBCR(S) VTCR
TTBR	Translation Table Base Register	TTBR0_EL1 TTBR0_EL2 TTBR0_EL3 TTBR1_EL1 VTTBR_EL2	TTBR0 TTBR1 HTTBR VTTBR

Table K14-1 Disambiguation of general names of registers by Execution state (continued)

General name	Short description	AArch64 register	AArch32 register
VCR	PL1&0 stage 2 Translation Control Register	VTCR_EL2	VTCR
VBAR	Vector Base Address Register	VBAR_EL1 VBAR_EL2 VBAR_EL3	VBAR HVBAR MVBAR
VTTBR	PL1&0 stage 2 Translation Table Base Register	VTTBR_EL2	VTTBR

Table K14-2 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

Table K14-2 Disambiguation of general names of the Performance Monitors System registers by Execution state

General name	Short description	AArch64 register	AArch32 register
PMCCFILTR	Cycle Count Filter Register	PMCCFILTR_EL0	PMCCFILTR
PMCCNTR	Cycle Count Register	PMCCNTR_EL0	PMCCNTR
PMCEID0	Performance Monitors Cycle Count Filter Register 0	PMCEID0_EL0	PMCEID0
PMCEID1	Performance Monitors Cycle Count Filter Register 1	PMCEID1_EL0	PMCEID1
PMCNTENCLR	Performance Monitors Count Enable Clear register	PMCNTENCLR_EL0	PMINTENCLR
PMCNTENSET	Performance Monitors Count Enable Set register	PMCNTENSET_EL0	PMCNTENSET
PMCR	Performance Monitors Control Register	PMCR_EL0	PMCR
PMEVCNTR<n>	Performance Monitors Event Count Registers, n = 0-30	PMEVCNTR<n>_EL0	PMEVCNTR<n>
PMEVTYPER<n>	Performance Monitors Event Type Registers, n = 0-30	PMEVTYPER<n>_EL0	PMEVTYPER<n>
PMINTENCLR	Performance Monitors Interrupt Enable Clear register	PMINTENCLR_EL1	PMINTENCLR
PMINTENSET	Performance Monitors Interrupt Enable Set register	PMINTENSET_EL1	PMINTENSET
PMMIR	Performance Monitors Machine Identification Register	PMMIR_EL1	PMMIR
PMOVSCLR	Performance Monitors Overflow Flag Status Register	PMOVSCLR_EL0	PMOVSR
PMOVSSET	Performance Monitors Overflow Flag Status Set register	PMOVSSET_EL0	PMOVSSET
PMSELR	Performance Monitors Event Counter Selection Register	PMSELR_EL0	PMSELR
PMSWINC	Performance Monitors Software Increment register	PMSWINC_EL0	PMSWINC
PMUSERENR	Performance Monitors User Enable Register	PMUSERENR_EL0	PMUSERENR
PMXEVCNTR	Performance Monitors Selected Event Count Register	PMXEVCNTR_EL0	PMXEVCNTR
PMXEVTYPER	Performance Monitors Selected Event Type Register	PMXEVTYPER_EL0	PMXEVTYPER

Register	Description, see
CNTV_CVAL_EL0	*CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register* on page D13-3767
CNTV_TVAL_EL0	*CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register* on page D13-3771
CNTVCT_EL0	*CNTVCT_EL0, Counter-timer Virtual Count register* on page D13-3774
CNTVOFF_EL2	*CNTVOFF_EL2, Counter-timer Virtual Offset register* on page D13-3776
CONTEXTIDR_EL1	*CONTEXTIDR_EL1, Context ID Register (EL1)* on page D13-2886
CONTEXTIDR_EL2	*CONTEXTIDR_EL2, Context ID Register (EL2)* on page D13-2889
CPACR_EL1	*CPACR_EL1, Architectural Feature Access Control Register* on page D13-2892
CPP RCTX	*CPP RCTX, Cache Prefetch Prediction Restriction by Context* on page C5-743
CPTR_EL2	*CPTR_EL2, Architectural Feature Trap Register (EL2)* on page D13-2897
CPTR_EL3	*CPTR_EL3, Architectural Feature Trap Register (EL3)* on page D13-2905
CSSELR_EL1	*CSSELR_EL1, Cache Size Selection Register* on page D13-2909
CTR_EL0	*CTR_EL0, Cache Type Register* on page D13-2912
CurrentEL	*CurrentEL, Current Exception Level* on page C5-375
DACR32_EL2	*DACR32_EL2, Domain Access Control Register* on page D13-2915
DAIF	*DAIF, Interrupt Mask Bits* on page C5-377
DBGAUTHSTATUS_EL1	*DBGAUTHSTATUS_EL1, Debug Authentication Status register* on page D13-3430
DBGBCR<n>_EL1	*DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page D13-3432
DBGBVR<n>_EL1	*DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page D13-3436
DBGCLAIMCLR_EL1	*DBGCLAIMCLR_EL1, Debug Claim Tag Clear register* on page D13-3442
DBGCLAIMSET_EL1	*DBGCLAIMSET_EL1, Debug Claim Tag Set register* on page D13-3444
DBGDTR_EL0	*DBGDTR_EL0, Debug Data Transfer Register, half-duplex* on page D13-3446
DBGDTRRX_EL0	*DBGDTRRX_EL0, Debug Data Transfer Register, Receive* on page D13-3449
DBGDTRTX_EL0	*DBGDTRTX_EL0, Debug Data Transfer Register, Transmit* on page D13-3451
DBGPRCR_EL1	*DBGPRCR_EL1, Debug Power Control Register* on page D13-3453
DBGVCR32_EL2	*DBGVCR32_EL2, Debug Vector Catch Register* on page D13-3455
DBGWCR<n>_EL1	*DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15* on page D13-3459
DBGWVR<n>_EL1	*DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15* on page D13-3463
DC CGDSW	*DC CGDSW, Data, Allocation Tag or unified Cache line Clean of Data and Allocation Tags by Set/Way* on page C5-460
DC CGDVAC	*DC CGDVAC, Data, Allocation Tag or unified Cache line Clean of Allocation Tags by VA to PoC* on page C5-462
DC CGDVADP	*DC CGDVADP, Data, Allocation Tag or unified Cache line Clean of Allocation Tags by VA to PoDP* on page C5-464

SPSR_EL3	*SPSR_EL3, Saved Program Status Register (EL3)* on page C5-434
SPSR_fiq	*SPSR_fiq, Saved Program Status Register (FIQ mode)* on page C5-441
SPSR_irq	*SPSR_irq, Saved Program Status Register (IRQ mode)* on page C5-445
SPSR_und	*SPSR_und, Saved Program Status Register (Undefined mode)* on page C5-449
SSBS	*SSBS, Speculative Store Bypass Safe* on page C5-453
TCO	*TCO, Tag Check Override* on page C5-455
TCR_EL1	*TCR_EL1, Translation Control Register (EL1)* on page D13-3314
TCR_EL2	*TCR_EL2, Translation Control Register (EL2)* on page D13-3327
TCR_EL3	*TCR_EL3, Translation Control Register (EL3)* on page D13-3344
TFSR_EL1	*TFSR_EL1, Tag Fail Status Register (EL1).* on page D13-3352
TFSR_EL2	*TFSR_EL2, Tag Fail Status Register (EL2).* on page D13-3356
TFSR_EL3	*TFSR_EL3, Tag Fail Status Register (EL3).* on page D13-3359
TFSRE0_EL1	*TFSRE0_EL1, Tag Fail Status Register (EL0).* on page D13-3350
TLBI ALLE1	*TLBI ALLE1, TLB Invalidate All, EL1* on page C5-544
TLBI ALLE1IS	*TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable* on page C5-545
TLBI ALLE1OS	*TLBI ALLE1OS, TLB Invalidate All, EL1, Outer Shareable* on page C5-546
TLBI ALLE2	*TLBI ALLE2, TLB Invalidate All, EL2* on page C5-547
TLBI ALLE2IS	*TLBI ALLE2IS, TLB Invalidate All, EL2, Inner Shareable* on page C5-548
TLBI ALLE2OS	*TLBI ALLE2OS, TLB Invalidate All, EL2, Outer Shareable* on page C5-549
TLBI ALLE3	*TLBI ALLE3, TLB Invalidate All, EL3* on page C5-550
TLBI ALLE3IS	*TLBI ALLE3IS, TLB Invalidate All, EL3, Inner Shareable* on page C5-551
TLBI ALLE3OS	*TLBI ALLE3OS, TLB Invalidate All, EL3, Outer Shareable* on page C5-552
TLBI ASIDE1	*TLBI ASIDE1, TLB Invalidate by ASID, EL1* on page C5-553
TLBI ASIDE1IS	*TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable* on page C5-555

K14.3 Functional index of AArch64 registers and System instructions

This section is an index of the AArch64 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- *Special-purpose registers*.
- *VMSA-specific registers* on page K14-7831.
- *ID registers* on page K14-7832.
- *Performance monitors registers* on page K14-7833.
- *Debug registers* on page K14-7834.
- *RAS registers* on page K14-7835.
- *Generic timer registers* on page K14-7835.
- *Cache maintenance system instructions* on page K14-7836.
- *Address translation system instructions* on page K14-7837.
- *TLB maintenance system instructions* on page K14-7838.
- *Prediction restriction System instructions* on page K14-7840.
- *Base system registers* on page K14-7841.

K14.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

Table K14-7 Special-purpose registers

Register	Description, see
ELR_EL1	ELR_EL1
ELR_EL2	ELR_EL2
ELR_EL3	ELR_EL3
SP_EL0	SP_EL0
SP_EL1	SP_EL1
SP_EL2	SP_EL2
SP_EL3	SP_EL3
SPSR_abt	SPSR_abt
SPSR_EL1	SPSR_EL1
SPSR_EL2	SPSR_EL2
SPSR_EL3	SPSR_EL3
SPSR_fiq	SPSR_fiq
SPSR_irq	SPSR_irq
SPSR_und	SPSR_und

K14.5 Functional index of AArch32 registers and System instructions

This section is an index of the AArch32 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- *Special-purpose registers*.
- *VMSA-specific registers*.
- *ID registers* on page K14-7856.
- *Performance monitors registers* on page K14-7857.
- *Debug registers* on page K14-7858.
- *RAS registers* on page K14-7859.
- *Generic timer registers* on page K14-7860.
- *Cache maintenance system instructions* on page K14-7861.
- *Address translation system instructions* on page K14-7861.
- *TLB maintenance system instructions* on page K14-7862.
- *Legacy feature registers and system instructions* on page K14-7863.
- *Base system registers* on page K14-7863.

K14.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

Table K14-20 Special-purpose registers

Register	Description, see
DLR	DLR
DSPSR	DSPSR
ELR_hyp	ELR_hyp
SPSR	SPSR
SPSR_abt	SPSR_abt
SPSR_fiq	SPSR_fiq
SPSR_hyp	SPSR_hyp
SPSR_irq	SPSR_irq
SPSR_mon	SPSR_mon
SPSR_svc	SPSR_svc
SPSR_und	SPSR_und

K14.5.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table K14-21 VMSA-specific registers

Register	Description, see
AMAIR0	AMAIR0
AMAIR1	AMAIR1
CONTEXTIDR	CONTEXTIDR

K14.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group. Each of the following sections lists the registers for a functional group:

- *ID registers*.
- *Performance monitors registers*.
- *Debug registers* on page K14-7876.
- *RAS registers* on page K14-7877.
- *Cross-trigger interface registers* on page K14-7878.

K14.7.1 ID registers

This section is an index to the registers in the Identification registers functional group.

Table K14-34 ID registers

Glossary

A32 instruction A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.

A32 instructions were previously called ARM instructions.

See also A32 state, A64 instruction, T32 instruction.

A32 state The AArch32 Instruction set state in which the PE executes A32 instructions.

A32 state was previously called ARM state.

See also T32 instruction, T32 state.

A64 instruction A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.

See also A32 instruction, T32 instruction.

AArch32 The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets

See also AArch64, A32 instruction, T32 instruction.

AArch64 The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

See also AArch32, A64 instruction.

Abort An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.

Addressing mode

Means a method for generating the memory address used by a load/store instruction.

Advanced SIMD A feature of the Arm architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Aligned
A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

Architecturally executed
An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a `NOP` because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

See also Condition code check, Simple sequential execution.

Architecturally mapped
Where this manual describes a register as being *architecturally mapped* to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.

Architecturally UNKNOWN
An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of UNKNOWN. Implementations can define the value of the field, but are not required to do so.

See also IMPLEMENTATION DEFINED.

ARM core registers
Some older documentation uses *ARM core registers* to refer to the following set of registers for execution in AArch32 state:

- The 13 general-purpose registers, R0-R12, that software can use for processing.
- SP, the *stack pointer*, that can also be referred to as R13.
- LR, the *link register*, that can also be referred to as R14.
- PC, the *program counter*, that can also be referred to as R15.

See also General-purpose registers.

ARM instruction
See A32 instruction.

Associativity
See Cache associativity.

Atomicity
Describes either single-copy atomicity or multi-copy atomicity. *Atomicity in the Arm architecture* on page B2-110 defines these forms of atomicity for the Arm architecture.

See also Multi-copy atomicity, Single-copy atomicity.

Banked register
A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

Base register
A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.

Base register writeback
Describes writing back a modified value to the base register used in an address calculation.

Behaves as if
Where this manual indicates that a PE *behaves as if* a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

Big-endian memory
Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also Endianness, Little-endian memory.

Blocking Describes an operation that does not permit following instructions to be executed before the operation completes.

A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also Prefetching.

Breakpoint A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte An 8-bit data item.

Cache associativity

The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

Cache level The position of a cache in the cache hierarchy. In the Arm architecture, the lower numbered levels are those closest to the PE. For more information, see *Terms used in describing the cache maintenance instructions* on page D4-2478.

Cache line The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown

Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set.

Coherence order

See Coherent.

Coherent Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the *coherence order* for that byte in memory.

Condition code check

The process of determining whether a conditional instruction executes normally or is treated as a `NOP`. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of PSTATE.IT determines whether the instruction is executed normally.

See also Condition code field, Condition flags, Conditional execution.

Condition code field

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also Condition code check.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Condition flags The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

See also Condition code check, PSTATE.

Conditional execution
When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a `NOP`.

See also Condition code check.

CONSTRAINED UNPREDICTABLE
Where an instruction can result in UNPREDICTABLE behavior, the Armv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRAINED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

See also UNPREDICTABLE.

Context switch The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

Context synchronization event
One of:

- Performing an ISB operation. An ISB operation is performed when an `ISB` instruction is executed and does not fail its condition code check.
- Exception entry, if ARMv8.5-CSEH is not implemented or the exception is taken to AArch32 or if ARMv8.5-CSEH is implemented and the appropriate SCTLR_ELx.EIS bit is set.
- Return from an exception, if ARMv8.5-CSEH is not implemented, or the exception is returning from AArch32 or if ARMv8.5-CSEH is implemented and the appropriate SCTLR_ELx.EOS bit is set.
- Exit from Debug state.
- Executing a `DCPS` instruction.
- Executing a `DRPS` instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.
- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.
- All completed changes to the translation tables for entries that, before the change, were not permitted to be cached in a TLB, affect all instruction fetches that appear in program order after the instruction causing the Context synchronization event.
- All invalidations of TLBs, instruction caches, and, in AArch32 state, branch predictors, that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch32 state, all Non-cacheable writes that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.
- Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.

Note

- The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that the performance monitor counters are permitted to reveal such speculation.
- *Context synchronization events* were previously described as *context synchronization operations*.

Data independent timing (DIT)
The time that it takes to execute a piece of code where the time is not a function of the data being operated on. For more information, see *About PSTATE.DIT* on page B1-105 and *About the DIT bit* on page E1-3793.

Debugger In most of this manual, *debugger* refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See:
- *Definition of a debugger in the context of self-hosted debug* on page D2-2398.
- *Definition of a debugger in the context of self-hosted debug* on page G2-5612.
- *Definition and constraints of a debugger in the context of external debug* on page H1-6700.

Deprecated Something that is present in the Arm architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the Arm architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the Arm architecture.

See also OPTIONAL.

Digital signal processing (DSP)
Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

Direct Memory Access (DMA)
An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

Direct read A direct read of a System register is a read performed by a System register access instruction.

For more information, see *Direct read* on page D13-2821.

See also Direct write, Indirect read, Indirect write.

Direct write A direct write of a System register is a write performed by a System register access instruction.

For more information, see *Direct write* on page D13-2821.

See also Direct read, Indirect read, Indirect write.

DMA *See* Direct Memory Access (DMA).

DNM *See* Do-Not-Modify (DNM).

Domain In the Arm architecture, *domain* is used in the following contexts.

Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

Power domain Defines a block of logic with a single, common, power supply.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Memory regions domain

When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the *Domain Access Control Register* (DACR). Arm deprecates any use of memory regions domains.

Do-Not-Modify (DNM)

Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value

Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Doubleword A 64-bit data item. Doublewords are normally at least word-aligned in Arm systems.

Doubleword-aligned

Means that the address is divisible by 8.

DSP *See* Digital signal processing (DSP).

Effective value A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an *Effective value*:

- In some cases, the description of a control *a* specifies that when control *a* is active it causes a register control field *b* to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field *b*. When control *a* is active that fixed value is described as the *Effective value* of register control field *b*. For example, when the value of HCR.DC is 1, the *Effective value* of HCR.VM is 1, regardless of its actual value.

  In other cases, in some contexts a register control field *b* is not implemented or is not accessible, but behavior of the PE is as if control field *b* was implemented and accessible, and had a particular value. In this case, that value is the *Effective value* of register control field *b*.

  Note

  Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an *Effective value* in that earlier version of the architecture.

- Otherwise, the *Effective value* of a register control field is the value of that field.

Endianness An aspect of the system memory mapping.

See also Big-endian memory and Little-endian memory.

Exception Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector

A fixed address that contains the address of the first instruction of the corresponding exception handler.

Execution stream

The stream of instructions that would have been executed by sequential execution of the program.

Explicit access A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

External abort An abort that is generated by the external memory system.

Fast Context Switch Extension (FCSE)

Modifies the behavior of an Arm memory system to enable multiple programs running on the Arm PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From Armv6, Arm deprecates any use of the FCSE. The FCSE is:

- Optional in an Armv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FCSE *See* Fast Context Switch Extension (FCSE).

Flat address mapping
Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode
A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers
The registers that the base instructions use for processing:

- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

  Note

  Older documentation defines the AArch32 general-purpose registers as R0-R12, and the Arm core registers as R0-R12, SP, LR, and PC.

- In AArch64 state the general-purpose registers are:
  — W0-W30 when accessed as 32-bit registers.
  — X0-X30 when accessed as 64-bit registers.

See also High registers, Low registers.

Generated by The memory model is written in terms of reads from memory and writes to memory. These reads and writes:

- Are generated by instructions such as loads, stores, and atomic memory accesses.
- Correspond to the memory accesses, other than translation table walks, that are defined in the instruction pseudocode.

Some instructions generate more than one read or write.

Halfword A 16-bit data item. Halfwords are normally halfword-aligned in Arm systems.

Halfword-aligned
Means that the address is divisible by 2.

High registers In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

Note

In some contexts, *high registers* refers to R8-R15, meaning R8-R14 and the PC.

See also General-purpose registers, Low registers.

High vectors An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

IGNORED Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields
Are unsigned unless otherwise stated.

Immediate value
A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMPLEMENTATION DEFINED
Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

Index register A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Indirect read When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see *Indirect read* on page D13-2821.

See also Direct read, Direct write, Indirect write.

Indirect write An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a *Direct write* to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.

For more information, see *Indirect write* on page D13-2821.

See also Direct read, Direct write, Indirect read.

Inline literals These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

Intermediate physical address (IPA)
An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.

See also Physical address (PA), Virtual address (VA).

Interworking A method of working that permits branches between software using the A32 and T32 instruction sets.

IPA *See* Intermediate physical address (IPA).

Level *See* Cache level.

Level of Coherence (LoC)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see *Terms used in describing the cache maintenance instructions* on page D4-2478.

See also Cache level, Point of coherency (PoC).

Level of Unification, Inner Shareable (LoUIS)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see *Terms used in describing the cache maintenance instructions* on page D4-2478.

See also Cache level, Point of unification (PoU).

Level of Unification, uniprocessor (LoUU)
For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see *Terms used in describing the cache maintenance instructions* on page D4-2478.

See also Cache level, Point of unification (PoU).

Line *See* Cache line.

Little-endian memory
Means that, for example:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also Big-endian memory, Endianness.

Load/Store architecture
An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC *See* Level of Coherence (LoC).

LoUIS *See* Level of Unification, Inner Shareable (LoUIS).

LoUU *See* Level of Unification, uniprocessor (LoUU).

Lockdown *See* Cache lockdown.

Low registers In AArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also General-purpose registers, High registers.

Memory barrier *See Memory barriers* on page B2-124.

Memory coherency
The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

Memory Management Unit (MMU)
Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

Memory Protection Unit (MPU)
A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

Miss *See* Cache miss.

MMU *See* Memory Management Unit (MMU).

MPU *See* Memory Protection Unit (MPU).

Multi-copy atomicity
The form of atomicity described in *Requirements for multi-copy atomicity* on page B2-112.

See also Atomicity, Single-copy atomicity.

NaN Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a *quiet* NaN, that propagate through most floating-point operations, or a *signaling* NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the *IEEE Standard for Floating-point Arithmetic*.

See also Quiet NaN, Signaling NaN.

Natural eviction A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

Observer A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

Obsolete Obsolete indicates something that is no longer supported by Arm. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing
Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

OPTIONAL When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the Arm architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. Arm expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.

  A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.

- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the Arm architecture after the initial release of that version of the architecture. Arm recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

Note

Do not confuse these Arm-specific uses of OPTIONAL with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice, for example the optional byte order reversal in an Armv7-R implementation, where the SCTLR.IE bit indicates the implemented option.

See also Deprecated.

PA *See* Physical address (PA).

PE *See* Processing element (PE).

Physical address (PA)
An address that identifies a location in the physical memory map.

See also Intermediate physical address (IPA), Virtual address (VA).

PoC *See* Point of coherency (PoC).

PoP *See* Point of persistence (PoP).

PoU *See* Point of unification (PoU).

Point of coherency (PoC)
For a particular VA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see *Terms used in describing the cache maintenance instructions* on page D4-2478.

Point of persistence (PoP)
The point in a memory system where there is a system guarantee that there is sufficient energy within the system to ensure that a write to memory will be persistent if system power is removed. For more information, see *Terms used in describing the cache maintenance instructions* on page D4-2478.

Point of unification (PoU)
For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see *Terms used in describing the cache maintenance instructions* on page D4-2478.

Post-indexed addressing
Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

Note

The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

See also Simple sequential execution.

Pre-indexed addressing
Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Processing element (PE)
The abstract machine defined in the Arm architecture, as documented in an Arm Architecture Reference Manual. A PE implementation compliant with the Arm architecture must conform with the behaviors described in the corresponding Arm Architecture Reference Manual.

Protection region
A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit *See* Memory Protection Unit (MPU).

Pseudo-instruction
UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

PSTATE An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also Condition flags.

Quadword A 128-bit data item. Quadwords are normally at least word-aligned in Arm systems.

Quadword-aligned
Means that the address is divisible by 16.

Quiet NaN A NaN that propagates unchanged through most floating-point operations.

See also NaN, Signaling NaN.

RAO *See* Read-As-One (RAO).

RAZ *See* Read-As-Zero (RAZ).

RAO/SBOP In versions of the Arm architecture before Armv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In Armv8, RES1 replaces this description.

See also UNK/SBOP, Read-As-One (RAO), RES1, Should-Be-One-or-Preserved (SBOP).

RAO/WI Read-As-One, Writes Ignored.

Hardware must implement the field as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also Read-As-One (RAO).

RAZ/SBZP In versions of the Arm architecture before Armv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In Armv8, RES0 replaces this description.

See also UNK/SBZP, Read-As-Zero (RAZ), RES0, Should-Be-Zero-or-Preserved (SBZP).

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RAZ/WI Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also Read-As-Zero (RAZ).

Read-allocate cache
A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)
Hardware must implement the field as reading as all 1s.

Software:

- Can rely on the field reading as all 1s.
- Must use a SBOP policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also RAO/SBOP, RAO/WI, RES1.

Read-As-Zero (RAZ)
Hardware must implement the field as reading as all 0s.

Software:

- Can rely on the field reading as all 0s
- Must use a SBZP policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also RAZ/SBZP, RAZ/WI, RES0.

Read, modify, write
In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

RES0 A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES0 in some defined architectural context.
- Has different defined behavior in a different architectural context.

Note

- RES0 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES0 for fields in read/write registers is:

If a bit is RES0 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
   - Reads of the bit always return 0.
   - Writes to the bit are ignored.
2. The bit can be written. In this case:
   - An indirect write to the register sets the bit to 0.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES0 only in some contexts

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also Read-As-Zero (RAZ), RES1, Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

RES1

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

Note

- RES1 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This means the definition of RES1 for fields in read/write registers is:

If a bit is RES1 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
   - Reads of the bit always return 1.
   - Writes to the bit are ignored.
2. The bit can be written. In this case:
   - An indirect write to the register sets the bit to 1.
   - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.

     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   - A direct write to the bit must update a storage location associated with the bit.
   - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES1 only in some contexts

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

  Note

  As indicated in this list, this value might be written by an indirect write to the register.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an SBOP policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also Read-As-One (RAO), RES0, Should-Be-One-or-Preserved (SBOP), UNKNOWN.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Reserved

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW or WO register, RES0.
  - In an RO register, UNK.

See also CONSTRAINED UNPREDICTABLE, RES0, RES1, UNDEFINED, UNK, UNPREDICTABLE.

RISC

Reduced Instruction Set Computer.

Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the *IEEE Standard for Floating-point Arithmetic*, see *Floating-point standards, and terminology* on page A1-53.

Saturated arithmetic

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in Arm processors, in which overflowing results wrap around from $+2^{31}-1$ to -2^{31} or vice versa.

SBO

See Should-Be-One (SBO).

SBOP

See Should-Be-One-or-Preserved (SBOP).

SBZ

See Should-Be-Zero (SBZ).

SBZP

See Should-Be-Zero-or-Preserved (SBZP).

Security hole

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The Arm architecture forbids security holes.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Self-modifying code

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see *Caches and memory hierarchy* on page B2-133.

Set

See Cache sets.

Should-Be-One (SBO)

Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-One-or-Preserved (SBOP)

From the introduction of the Armv8 architecture, the description *Should-Be-One-or-Preserved (SBOP)* is superseded by *RES1*.

Note

The Armv7 Large Physical Address Extension modified the definition of SBOP for register bits that are SBOP in some but not all contexts. The behavior of these bits is covered by the *RES1* definition, but not by the generic definition of SBOP given here.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Hardware must ignore writes to the field.

When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-Zero (SBZ)

Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Should-Be-Zero-or-Preserved (SBZP)

From the introduction of the Armv8 architecture, the description *Should-Be-Zero-or-Preserved (SBZP)* is superseded by *RES0*.

Note

The Armv7 Large Physical Address Extension modified the definition of SBZP for register bits that are SBZP in some but not all contexts. The behavior of these bits is covered by the *RES0* definition, but not by the generic definition of SBZP given here.

Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also CONSTRAINED UNPREDICTABLE, UNPREDICTABLE.

Signaling NaN

An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also NaN, Quiet NaN.

Signed immediate and offset fields

Are encoded in two's complement notation unless otherwise stated.

SIMD

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in *Parallel addition and subtraction instructions* on page F1-3876.
- The Advanced SIMD instructions summarized in *Advanced SIMD and floating-point instructions* on page E1-3794, when operating on vectors.

  Note

  In Armv7, some VFP instructions can operate on vectors. However, Arm deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Simple sequential execution
The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and Arm does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity
The form of atomicity described in *Properties of single-copy atomic accesses* on page B2-112.

See also Atomicity, Multi-copy atomicity.

Single-precision value
A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Spatial locality The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

Speculative
Speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.
- Reads or writes generated by load or store instructions for which the data being written or the address being accessed comes from a register that has not been architecturally resolved.
- Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.

See also Execution stream.

Special-purpose register
One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- *Special-purpose registers* on page C5-374 specifies the AArch64 Special-purpose registers.
- *AArch32 Special-purpose registers* on page G1-5490 lists the AArch32 Special-purpose registers.

T32 instruction One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also A32 instruction, A64 instruction, T32 state.

T32 state The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also A32 state, T32 instruction.

Taken locally *Taken locally* is a qualifier that determines which instances of an exception are counted by particular PMU events. See, in particular, *Arm recommendations for IMPLEMENTATION DEFINED event numbers* on page K3-7666.

In this context, an exception that is *Taken locally* means an exception that is one of:

- Taken to the current Exception level.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This is not possible when the current Exception level is EL0.

- Taken from EL0 to EL1.
- Taken from EL0 to EL2 because the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Note

An exception taken from EL0 to EL2 because the *Effective value* of HCR_EL2.{E2H, TGE} is {0, 1} is not *Taken locally*. This includes exceptions taken to EL2 using AArch32 when HCR.TGE is 1.

Temporal locality
The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

Thumb instruction
See T32 instruction.

TLB *See* Translation Lookaside Buffer (TLB).

TLB lockdown A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

Translation Lookaside Buffer (TLB)
A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the Arm implementation.

Translation table
A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

Translation table walk
The process of doing a full translation table lookup. It is performed automatically by hardware.

Trap enable bits In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

Unaligned An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Unaligned memory accesses
Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE.

UNDEFINED Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to:

- Any encoding that is not allocated to any instruction.
- Any encoding that is defined as never accessible at the current Exception level.
- Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level.

If the generated exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

Copyright © 2013-2019 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also *Undefined Instruction exception* on page G1-5536.

Unified cache Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing

Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In Armv7 and earlier versions of the Arm architecture, and in the M-profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

UNK An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also UNKNOWN.

UNK/SBOP Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

UNK/SBZP Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

UNKNOWN An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNK, UNPREDICTABLE.

UNPREDICTABLE

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Non-Confidential

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE, UNDEFINED.

VA *See* Virtual address (VA).

VFP In Armv7, an extension to the Arm architecture, that provides single-precision and double-precision floating-point arithmetic.

Virtual address (VA)
An address generated by an Arm PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

See also Intermediate physical address (IPA), Physical address (PA).

Watchpoint A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

Way *See* Cache way.

WI Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also RAO/WI, RAZ/WI, RES0, RES1.

Word A 32-bit data item. Words are normally word-aligned in Arm systems.

Word-aligned Means that the address is divisible by 4.

Write-allocate cache
A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back cache
A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

Write-through cache
A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

Write buffer A block of high-speed memory that optimizes stores to main memory.
